1.0 ABSTRACT

This diagnostic has two starting addresses:

200 standard tolerances
204 restart
210 tighter tolerances for the option test area's burn in.

This diagnostic tests the ADV11 with or without the BERG test connector.

When starting the diagnostic, a set of tests is listed and this statement is printed out: "Type the letter and carriage return of the desired test:". The following chart indicates which letter corresponds to which test:

W: The entire Wraparound test (requires BERG test connector)

- a. Analog subtests
- b. Noise test
- c. Interchannel Settling test
- d. Differential Linearity and Relative Accuracy test

C: Calibration test only

P: Print values test only

L: Logic Subtests only

A: Auto test (requires BERG test connector)

- A. Logic subtests
- B. Analog subtests
- C. Noise Test
- D. Interchannel Settling Test
- E. Differential Linearity and Relative Accuracy Test

2.0 REQUIREMENTS

2.1 Equipment

LSI-11 computer with 8K of memory
I/O Terminal
ADV11 Module
VT55 Terminal supported for graphic output
BERG test connector

2.2 Storage

This program uses all 8K of memory and is not "chainable" on an 8K CPU. The program is "chainable" on 12K or greater CPU. The program will destroy "absolute loader" on an 8K CPU, if 'W' or 'A' is selected.

3.0 LOADING PROCEDURE

Procedure for loading normal binary tapes should be followed.

4.0 STARTING PROCEDURE

4.1 Control Switch Settings

Standard PDP-11 Format

SW15=1	Halt on error
SW14=1	Loop on test
SW13=1	Inhibit error timeouts
SW12=1	Halt for VT55 display
SW11=1	Inhibit iterations
SW10=1	Bell on error
SW9 =1	Loop on error
SW8 =1	Loop on test in SWR <7:0>

200 is the starting address of the diagnostic for standard tolerances. 204 is the restart address. 210 is the starting address of the diagnostic for the option test area's burn in test.

5.0 OPERATING PROCEDURE

Start the diagnostic at 200 or 210. The program heading and the list of tests available, will be printed out followed by a message 'Type letter and <CR> for test:'. Then type the letter you want, according to the table listed and depress return. If started at the option test area's starting address, the program will not ask for the test but will run the logic test.

Two control characters, ^A and ^C, are set aside for interrupting a test and transferring control to either the beginning of the diagnostic (^C) or to the beginning of the specific test which was in progress (^A). During the logic tests while a reset is being performed, ^C or ^A will not be executed until after the reset has been completed, therefore continue typing ^C or ^A until it is successful.

For machines without a hardware switch register, location SWREG (176) is used as a software switch register. To modify the contents of SWREG, type ^G. The program responds with the current contents of SWREG and a slash. Type the desired new contents of SWREG followed by a carriage return.

If 'W' is typed, the program will type 'XX ADV11's FOUND'. Where XX is the number of ADV11's in octal. If the number is greater than 1, the test will be run successively on each ADV11. The program will run through the analog subtests, the Noise test, the Interchannel Settling test, and the Differential Linearity and Relative Accuracy test. The BERG test connector is required.

If 'C' is typed, the program will run the calibration routine and loop on the test until it is calibrated and a carriage return typed. If a certain ADV11 is to be calibrated, its status register address must be loaded into \$BASE (1250), and its vector address must be loaded into the low byte of \$VECT1 (1244).

If 'P' is typed, the program will run the print values routine and will loop on that test until the operator halts it. If a certain ADV11 is to be tested, its status register address must be loaded into \$BASE (1250), and its vector address must be loaded into the low byte of \$VECT1 (1244).

If 'A' is typed, the program will execute the logic tests, analog tests, noise, settle and differential linearity. At the beginning of the test the program will type 'XX ADV11'S FOUND'. Where XX is the number of ADV11's in octal. If the number is greater than 1 the test will run successively on each ADV11.

If 'L' is typed, the program will execute the logic tests, printing 'END PASS' when it has completed an entire pass. At the beginning of the test the program will type 'XX ADV11'S FOUND'. Where XX is the number of ADV11's in octal. If the number is greater than 1, the test will be run successively on each ADV11.

5.1 Inhibiting Auto-Size Feature

This program will automatically auto-size and test each ADV11 it detects on the system. To inhibit this feature, set bit 15 of location \$ENVM (1214). Also, load location \$BASE (1250) with the ADV11's status register address and the low byte of location \$VECT1 (1244) with the ADV11's vector address.

5.2 End of Pass Typeouts

At end of pass, the following typeout will occur:

'ENDPASS GOOD UNITS 0000000000000011

This indicates that units 1 and 2 have run without failure.

6.0 ERRORS

This program uses the Diagnostic "SYSMAC" package for error reporting and typeout. The error information consists of the following:

ERRPC: Location at which an error was detected.
STREG: Address of the status register.
ADBUFF: Address of the buffer
CHANL: Channel value
NOMINAL: Expected correct data
TOLERANCE: The acceptable deviation from the nominal
ACTUAL: Actual data
EXPECTED: Expected correct data

7.0 MISCELLANEOUS

7.1 Execution Time

Execution time for each of the tests is:

Calibration:	5 conversions/min @110 baud
Print Values:	8 conversions/8 seconds @ 110 baud
Wraparound Test:	7 minutes first pass; 25 minutes for successive passes
Logic Test:	1 minute
Auto Test:	8 minutes first pass, 26 minutes for successive passes

7.2 Status Register and Vector Addresses and Priority

When testing more than one ADV11, the difference in addresses is 4 for bus address and 10 for vector address. These values are in VADR (bus address) (1332) and VVCT (vector address) (1334). The first ADV11's status register address must be in \$BASE (1250), its vector address must be in the low byte of \$VCT1 (1244).

7.3 Switch Register

If a hardware switch register is present and the operator desires to use a software switch register and the ^G feature; it is necessary to load the starting address, set the hardware switch register to all ones (-1), and depress start. The program will then run with the software switch register.

7.4 VT55 Graphic Output

The screen display may be halted for examination by setting bit 12 of the switch register. Then, type 'P' to complete the program's execution.

8.0 RESTRICTIONS

8.1 Testing

The BERG Test Connector must be present when running the auto test and the wraparound test.

8.2 Starting Restriction

If a free-running clock, such as 60Hz from the power supply, is attached to the BEVNT bus line on both Rev Level C/D and E systems, an interrupt to location 100 will occur when using the 'G' and 'L' commands prior to executing the first instruction. Therefore this program can not disable the BEVNT bus line by inhibiting interrupts.

User systems requiring a free-running clock attached to the BEVNT bus line can temporarily avoid this situation by setting the PSW(RS) to 200, instead of using the 'G' command, load the PC (R7) with the starting address and use the proceed 'P' command. Before using the 'L' command, the PSW(RS) can be set to 200 to avoid receiving the BEVNT interrupt after loading the ABS loader.

8.3 Possible Program 'BOMBS'

The first two tests of this program check to see if the ADV11 responds to the expected address. If the ADV11 does not respond, a bus error occurs. Also bus errors can occur during the time the program sizes to see how many ADV11's are on your system.

For more information on the next subject, see JAN. 1976 LSI-11 ENGINEERING BULLETIN issued by The Digital Components Group.

Bus errors may alter the preset contents of location 4 before the trap is executed, thereby transferring program control to area in the program that was not set up to handle the trap. If this happens, the program will 'BOMB' and possibly rewrite parts of itself.

9.0 PROGRAM DESCRIPTION

9.1 Logic Tests

These 23 logic subtests run sequentially without further operator intervention. Its purpose is to check that each of the status register bits that are read/write can be loaded and properly read back; that initialize clears the external start enable bit, the done bit, the interrupt enable bit, the overflow bit, the error flag, and the A/D start bit. It also checks that the A/D done flag sets at end of conversion and clears when the converted value is read. It checks the interrupt logic and the correct setting of the error flag.

9.2 Calibration Routine

If 'C' is typed, the program will ask for a channel. Type channel number followed by a carriage return. The program will ask you if you want offset or gain. Apply voltage requested to selected channel. Adjust pot requested for 0.00 SB typeout. Type carriage return when adjusted. The last typeout will be checked for 0.00 LSB with a tolerance of 0.04 LSB if outside, the program will ask you to adjust the same pot again.

9.3 Print Values Routine

This test begins when the operator types 'P'. It then loads the channel from the switch register bits 0-7 and does a conversion on that channel. If SWR bit 13 is down (0), it prints out the converted value on the teletype; otherwise, if SWR bit 13 is up (1), it puts the converted value in the display register. The operator may change the channel at any time during the test, however the new values from the new channel will not be printed until the next line of 8 values is printed. The 8 values on each line correspond to only one channel.

9.4 Differential Linearity

This test determine if a change in the input voltage represents a similar change in the resulting converted binary value, by measuring the width of each state correct to 0.01 LSB.

9.5 Settling Test

The purpose of this test is to check that the time needed to settle and correctly report a new input value after switching channels does not exceed the expected amount of time for such a change.

9.6 Noise Test

This test measures the internal short-term repeatability noise within the A/D. RMS noise equals 1 standard deviation of the Gaussian curve, PEAK noise equals 2.3 standard deviation of the Gaussian curve.

9.7 Analog Tests

These 6 subtests check the channels and their output.
