## 1.0 ABSTRACT

This program tests the LSI-11 floating instruction set <FADD, FSUB, FMUL, and FDIV> option with fixed number patterns, using each register at least once as the stack pointer. It also checks stack overflow and that the floating instructions can be interrupted (by the console teletype). [However, this test will not be executed when bit 5 of SENVM byte is high]. The program should be run for at least 2 passes with all switches low. The program is designed to run under APT, and ACT, systems. When running under APT, with bit 5 of SENVM low it will be required to have a SLU with TTY registers having addresses of 176560-66 and interrupt vectors of 70 for receiver and 74 for transmitter. Under such a condition it will also be required to change the run time of first pass from 5 seconds to the time given in Sec. 8.1, and the run time for the longest test from 3 seconds to 30 seconds.

## 2.0 REQUIREMENTS

LTC SWITCH MUST BE IN OFF POSITION TO RUN DIAGNOSTIC.

### 2.1 Equipment

LSI-11 standard computer with FIS option and 4K of memory.

### 2.2 Storage

Program Storage - The routines use memory 0 - 17500.

### 2.3 Preliminary Programs

None.

## 3.0 LOADING PROCEDURE

Use standard procedure for ABS Tapes.

## 4.0 STARTING PROCEDURE

### 4.1 Control Switch Settings

See 5.1.1 (all low for worst case testing).

### 4.2 Starting Address

After loading the program it should always be started at 200. If it is desired to save the pass counter then the program should be restarted at location RESTART (i.e. 222) otherwise the program can be restarted at 200.

### 4.3 Program And/or Operator Action

#### 4.3.1 Stand Alone -

1. Load program into memory using ABS loader.
2. Set switches (see Sec 5.1.1) all low except bit 7 for worst case.
3. Type 200G.
4. The program will loop and "END PASS" will be typed after completion of every pass. However type out will be suppressed if bit 5 of location \$ENVVM is high.
5. A minimum of two passes should always be run.

4.3.2 Under Apt - Load the program, set the switches (see Sec. 5.1.1) and start. When under API, with bit 5 of \$ENVVM low it will be required to have a SLU with TIV registers having addresses of 176560-66 and interrupt vectors of 70 for receiver and 74 for transmitter. Under such a condition it will also be required to change the run time of first pass from 5 seconds to the time given in Sec. 8.1, and the run time for the longest test from 3 seconds to 30 seconds. The test times and pass times are suggested with bit 7 of \$SWREG, low, if it is desired to enable the iterations then the times should be multiplied by a factor of 256.

## 5.0 OPERATING PROCEDURE

### 5.1 Operational Switch Settings

All switches low except SW<11> is worst case testing. With bit 11 of the location \$SWREG (i.e. location 422), high each subtest will be looped upon until completion of 256 passes of that subtest. 'END PASS' will be typed upon completion of a pass of the entire program. Alternate pass will run with the T-bit set.

5.1.1 Switch Settings Are - A 16 bit location called \$SWREG (i.e. location 422) has been used to give the following options by inserting a 1 in their respective positions.

| BIT # | OCTAL VALUE | FUNCTION                      |
|-------|-------------|-------------------------------|
| 15    | 100000..... | Halt On Error                 |
| 14    | 040000..... | Scope Loop                    |
| 13    | 020000..... | Inhibit Printout              |
| 12    | 010000..... | Inhibit Trace Trapping        |
| 11    | 004000..... | Enable Iterations Of Subtest  |
| 10    | 002000..... | Bell On Error                 |
| 09    | 001000..... | Loop On Error                 |
| 08    | 0004XX..... | Loop On Test In Bits 7 Thru 0 |

An 8 bit byte \$ENVM (i.e. location 421) has been used to define the operating mode. All timeouts can be suppressed by making bit 5 of byte \$ENVM high, in other words by placing a 20000 in location 420.

### 5.2 Subroutine Abstracts

5.2.1 Scope - This subroutine call (via a TRAP instruction) is placed between each subtest in the instruction section. It records the starting address of each subtest as it is being entered in location 'LA \$'. If a scope loop is requested, the current subtest will be looped upon. SW<11> is a 1 inhibits iteration of subtests. The contents of 'LADS' may be used to determine the last subtest successfully completed.

5.2.2 HLT - This routine (called by an EMT instruction) prints out an error message (see 6.1). If SW<9> is a 1 and a HLT is executed, the subtest will be looped upon until 256 consecutive good passes are completed. To inhibit timeouts, make SW<13> a 1. To ring the bell or an error, make SW<10> a 1. A high bit 5 in location \$ENVM will inhibit any timeouts and ringing of bells.

5.2.3 T Bit Trap - If SW<12> is a 0, the T-Bit will be set on alternate passes. When the T-Bit is set, the processor traps after each instruction. The first instruction executed upon trapping is an 'RTT' which returns to the interrupted sequence of instructions. This sequence is continued until the end of the program is reached.

5.2.4 Trap Catcher - A ".+2" - 'HALT' sequence is repeated from 0-776 to catch any unexpected traps. Thus any unexpected traps or interrupts will halt at the vector +2.

5.2.5 Floating Error Trap (To 244) - If a floating point error (overflow, underflow, or divide by zero) was expected, the vector will point to a unique ISR within the subtes: where the error occurred which checks the data on the stack(s). If an error was not anticipated, an erroneous trap will be detected in traper.

5.2.6 NOP - A NOP is placed just before each FIS instruction. This allows the operator to patch in a halt for debugging purposes.

## 6.0 ERRCRS

### 6.1 Error Printout

The format is as follows:

ERRNM ADR PS SP ANS1 ANS2 ANS3 ANS4 ANS5 ANS6

Where:

|         |   |
|---------|---|
| ERRNM : | - Error Number  |
| ADR     | = Address of Error HLT  |
| PS      | = Processor Status  |
| SP      | - Contents of Stack Pointer Register  |
| ANS1-6  | - Error Data Read from the Stack(s). From 0 to 6 o' these may be typed depending on the number following the HLT; e.g., HLT+3 would type ANS1 thru ANS3, HLT (by itself) would stop after ERRNM, ADR, PS, and SP. |

To find the failing test, loop at the listing above the address typed. In most cases the comment beside the HLT tells what was being checked and what was expected. All printouts will be suppressed when bit 5 of location SENVM is high. While running under APT the diagnostic will not support spooling of console outputs.

## 6.2 Error Recovery

Restart at 200 or 222 (see Sec. 4.2).

## 6.3 Error Counter

An error count is kept in location 'ERRORS'. It can only be cleared from the console or by reloading the program.

## 7.0 RESTRICTIONS

None.

## 8.0 MISCELLANEOUS

### 8.1 Execution Time

Due to the random characteristics of the interrupt tests, the execution time can be half a minute or more. However, normally 'END PASS' will be typed within 40 seconds with all switches down. Execution time will increase by a factor of 256 when iterations of each subtest are enabled.

### 8.2 Stack Pointer

Stack is initially set to 600.

### 8.3 Pass Count

A 16 bit location '\$PASS' (i.e. location 406) is used to keep pass count. It can be cleared by restarting the program at 200.

### 8.4 Test Number

A 16 bit location '\$TESTN' (i.e. location 404) is used to keep track of the test number. Upper byte of this location gives the iteration number and the lower byte the test that was being executed.

## 0008.5 Power fail

Each test can be power failed with no errors. To use, start the test as usual and power down then up at any time. The program should type 'POWER' and continue to run from where the power fail interrupted with no other error trapouts.

## 0009.0 PROGRAM DESCRIPTION

This program tests all the FIS instructions of the LSI-11 (FADD, FSUB, FMUL, and FDIV). All registers are checked to see if they function properly as the stack pointer. The program has many subtests (the code between 2 scope statements) which are run once before continuing to the next subtest. SW<11> set to a 1 causes each subtest to be run 00256 times. SW<9> set to a 1 enables loop on error. The location \$ICNT contains the iteration count and the location \$TESTN contains the test number. All the subtests should be run sequentially by starting at 00200 not by starting at the beginning of the subtest. To loop on a particular subtest, put the test number (see listing) in the right byte of the location \$SWREG and SW<8> set to a 1. This test will be looped upon until SW<8> is set to a 0 or the right byte is changed. If the test is non-existent, the program will be run as usual.
