I. OVERVIEW

The purpose of this analysis is to provide a basic understanding of the Shugart SA 850/450 floppy drive read chain electronics, and to provide a record for future references.

Experiments were performed where ever possible to provide comparisons between theoretical and actual results. It probably would be helpful to study the table of contents on appendix and also section twelve--summary of plots, more closely to visualize the comparisons.

A read chain block diagram is shown on page five.

II. READ CHANNEL FRONT END

The front end of read channel consists of read/write head, read damping resistors and steering diodes.

1. D.C. ANALYSIS:

The steering diodes are there to provide D.C. bias paths during the read mode, and to provide D.C. blocking during write mode. Side select is accomplished by the write chip center taps. A summary table is provided below:

	READ MODE		WRITE MODE	
	SIDE 0	SIDE 1	SIDE 0	SIDE 1
CT 0	LOW	HIGH	HIGH	LOW
CT 1	HIGH	LOW	LOW	HIGH

During write mode, the write chip data pins (6,7) provide high and low resistance paths, according to the input data, to accomplish the write function.

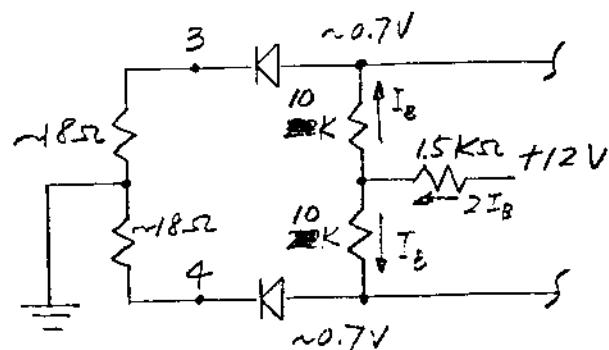

During read mode, pins (6,7) of write chip become an open circuit, hence no data would be written even if one of the center taps (the side that is not selected) is high.

There are also two diodes in front of the read chip to provide input clamping to prevent read chip from blowing up during transient and/or static discharge.

D.C. equivalent CKT of head in read mode is

SA 850

SA 450

D.C. bias current (D.C. current through the head):

SA 850:

$$I_B = \frac{12V - 0.7V}{22K}$$

$$\approx 0.51mA$$

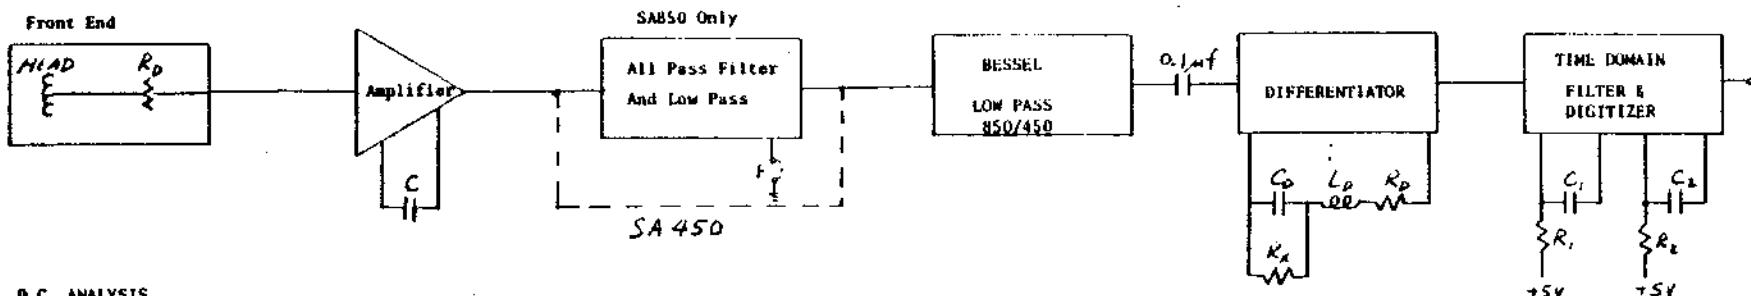

SA 450:

$$I_B = \frac{12V - 0.7V}{\frac{1.5K + 10K//10K}{2}}$$

$$\approx 0.87mA$$

The D.C. voltage at points 3 & 4 is, for all practical purposes, at ground.

2. EQUIVALENT CIRCUIT:

A complete model of the A.C. equivalent circuit is shown below:

L = Equivalent head inductance (full coil)

R_L = Head internal D.C. resistance

C_L = Equivalent distributed head capacitance

R_p = Pure resistance at resonance.

R_W = Pig tail wire resistance

C_W = Pig tail wire capacitance

R_D = Equivalent read damping resistance

C_A = Amplifier input capacitance

R_A = Amplifier input resistance

F_0 = Resonant frequency (Head and pigtail only)

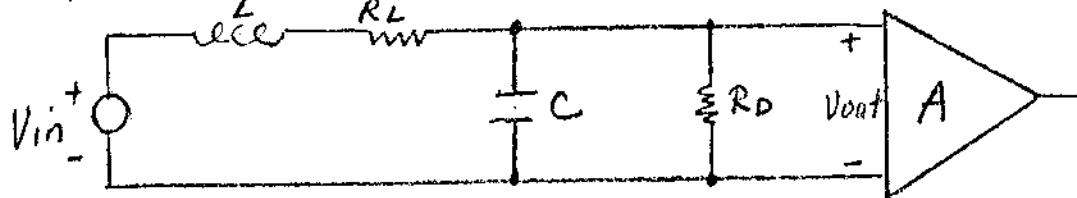

Typical readings of head and pigtail are:

	F_0	L	R_L	C_L	R_p	R_W	C_W	R_D		C_A	R_A
SIDE 0	513 Khz	1.91 mH	36ohm	48pf	76Kohm	4 ohm	1 pf	850	450	10pf	100kohm
SIDE 1	536 Khz	1.72 mH	36ohm	51pf	51Kohm	4 ohm	1 pf	5.9K ohm	4k ohm		

- * The readings for both side 0 & 1 are usually identical.
- The inductance is spec. for $18\text{mH} \pm 2\text{mH}$ and the capacitance is spec. for $12 \pm 3\text{pf}$.

3. TRANSFER FUNCTION: (Appendix A)

Due to the complexity of the above model and in consideration of the practicality, the model is being simplified as the following:

Assuming: $R_w = 0$, $R_p = R_A = \infty$

$$C = C_L + C_w + C_A$$

The transfer function as derived in appendix A is:

$$T(s) = \frac{1}{LC} \cdot \frac{s^2 + s(\frac{R_L}{L} + \frac{1}{CR_D}) + \frac{R_L + R_D}{LCR_D}}{s^2 + 2\zeta s + \frac{R_L + R_D}{LCR_D}}$$

$$2\zeta = (\frac{R_L}{L} + \frac{1}{CR_D}) ; \zeta = \text{Damping factor; not normalized}$$

$$\omega_0^2 = \frac{R_L + R_D}{LCR_D} \approx \frac{1}{LC} ; \omega_0 = 3 \text{ dB corner frequency}$$

$$|\zeta| = \frac{\zeta}{\omega_0} = \frac{1}{2R_D} \sqrt{\frac{L}{C}}$$

From the relationship listed above, it is obvious that head performance is degraded after connected to the amplifier. That is the head band-width is reduced due to the introduction of additional capacitance. For both 850/450:

$$f_o = \frac{1}{2\pi} \sqrt{\frac{1}{LC}} \quad (L = 1.91 \text{ mH}, C = 59 \text{ pf}) \quad (\text{natural frequency})$$

$$= 494 \text{ KHz} \quad (\text{Compare with } 513 \text{ KHz})$$

Bode plot of various L_s and C_s are plotted at Appendix A.

	L	C	R_D	$ \zeta $	OVERSHOOT %	f_o
SA 850	1.95 mH	50 pF	5.89K	0.502	15.2 %	538 KHz
	1.9 mH	59 pF		0.462	22 %	495 KHz
SA 450	1.75 mH	50 pF	4.0 K	0.74	0 %	538 KHz
	1.9 mH	59 pF		0.68	0 %	495 KHz

As can be noted from the plots for SA 850, peaking does not occur at f_o . For $|\zeta| < 0.1$, peaking occurs at f_o . For $0.1 > |\zeta| > 0.1$, peaking occurs at

$$f = f_o \sqrt{1 - 2|\zeta|^2} \quad (\text{peaking frequency})$$

Subject
UPDATES ON SA450/850 READ CHANNEL
ANALYSIS

Date
FEBRUARY 4, 1980

A mistake was discovered by Art Geffon on P. 18A of the report.

The equation for C_D is:

$$C_D = \frac{I_{max}}{A_{max} E_{max} W_{max}}$$

where E_{max} should have been defined as

$$\begin{aligned} E_{max} &= \text{Max. head output (zero to peak)} \\ &\leq 7 \text{ mV (O-P)} \end{aligned}$$

The error caused all subsequent calculations to be off by a factor of two. However, using the values calculated in the report would not affect the differentiator's performance in terms of frequency and linearity. The error resulted in a more conservative differentiator design. In other words, it increased the upper limit of the differentiator's input dynamic range. All other parameters were self-adjusted to compensate for the shift. Due to this conservative design, we might be sacrificing the low end sensitivity of the differentiator. Art is going to run some experiments to determine the effect.

BW:ds

4. READ DAMPING ANALYSIS:

For minimum phase distortion, group delay should equal to phase delay. Under this theoretical consideration, we would like to have a read damping factor of .866 and quality factor of .577. (See Appendix A --linear phase analysis). The damping factor indicates the amount of over shoot and it affects the amplitude and phase linearity of signal. Damping factor for SA 850:

$$|\zeta| = \frac{\zeta}{\omega_0} = \frac{1}{2R_D} \sqrt{\frac{L}{C}}$$

$$R_D = 6.8K // 2(2.2K) = 5.9K \text{ ohm}$$

$$\begin{aligned} |\zeta| &= 0.48 && (\text{Under Damped}) \\ |\zeta| &= 0.46 && (\text{if } L = 1.7 \text{ mH}, C = 59 \text{ pf}) \end{aligned}$$

SA 450:

$$R_D = 4.89K // 2(10K) = 4K \text{ ohm}$$

$$\begin{aligned} |\zeta| &= 0.71 \\ |\zeta| &= 0.68 && (\text{if } L = 1.7 \text{ mH}, C = 59 \text{ pf}) \end{aligned}$$

Given ZETA, the percent of overshoot, if occurs, can be calculated by

$$\text{Overshoot \%} = \left[\frac{1}{2|\zeta| \sqrt{1 - |\zeta|^2}} - 1 \right] 100\% \quad |\zeta| < .707$$

This equation is true for ZETA less than 0.707. For ZETA greater than .707, the system is over damped and no overshoot can occur. For an under-damped system, overshoot will occur yet the read back signal will have a narrower pulse width.

An experiment was done by Art Geffon to determine the damping factor. The result showed that a head with $L=1.7\text{mH}$, $C=59 \text{ pf}$, $R_D=5.9\text{k ohm}$ has ZETA equal to 0.43 (see Appendix A). This is very close to the calculated value.

*** Three parameters dictate the choice of damping factors. They are

- 1) head bandwidth entension consideration to retain more higher harmonics which would affect the margin; 2) signal to noise ratio which would also affect margin; 3) phase linearity which would affect signal linearity and margin to see P. 46 for linear phase analysis.

5. SENSITIVITY ANALYSIS:

In order to determine how component tolerance will affect various parameters, it is necessary to do a sensitivity analysis for individual parameter with respect to different components. Damping factor sensitivity will be considered.

$$S_{g_i}^{\frac{1}{\zeta}} \triangleq \frac{\frac{\partial \frac{1}{\zeta}}{\partial g_i}}{\frac{\partial g_i}{g_i}} = \frac{g_i}{\frac{1}{\zeta}} \cdot \frac{d \frac{1}{\zeta}}{d g_i}$$

(Sensitivity of $\frac{1}{\zeta}$ with respect to variable g_i)

$$S_{g_1+g_2+g_3+\dots}^{\frac{1}{\zeta}} \triangleq S_{g_1}^{\frac{1}{\zeta}} + S_{g_2}^{\frac{1}{\zeta}} + S_{g_3}^{\frac{1}{\zeta}} + \dots$$

$$S_{R_D+L+C}^{\frac{1}{\zeta}} = S_{R_D}^{\frac{1}{\zeta}} + S_L^{\frac{1}{\zeta}} + S_C^{\frac{1}{\zeta}}$$

$$\frac{\Delta \zeta}{\zeta} = \frac{\Delta R_D \frac{1}{\zeta}}{R_D} ; \frac{\Delta \zeta}{\zeta} = \frac{\Delta L}{L} \frac{1}{\zeta} ; \frac{\Delta \zeta}{\zeta} = \frac{\Delta C}{C} \frac{1}{\zeta}$$

Worst case analysis:

$$\frac{\Delta \zeta}{\zeta} = \frac{\Delta R_D}{R_D} S_{R_D}^{\frac{1}{\zeta}} + \frac{\Delta L}{L} S_L^{\frac{1}{\zeta}} + \frac{\Delta C}{C} S_C^{\frac{1}{\zeta}}$$

$$\therefore \frac{1}{\zeta} = \frac{1}{2R_D} \sqrt{\frac{L}{C}}$$

$$S_{R_D}^{\frac{1}{\zeta}} = \frac{R_D}{\zeta} \frac{d \zeta}{d R_D} = \frac{R_D}{2\zeta} \sqrt{\frac{L}{C}} \left(-\frac{1}{R_D^2} \right) = -\frac{1}{2\zeta R_D} \sqrt{\frac{L}{C}}$$

$$S_L^{\frac{1}{\zeta}} = \frac{L}{\zeta} \frac{d \zeta}{d L} = \frac{L}{\zeta} \frac{1}{4R_D \sqrt{LC}} = \frac{1}{4R_D \zeta} \sqrt{\frac{L}{C}}$$

$$S_C^{\frac{1}{\zeta}} = \frac{C}{\zeta} \frac{d \zeta}{d C} = \frac{C \sqrt{L}}{2\zeta R_D} \left(-\frac{1}{2} \right) (C)^{-\frac{3}{2}} = \frac{1}{4\zeta R_D} \sqrt{\frac{L}{C}}$$

$$\begin{aligned} \frac{\Delta \zeta}{\zeta} &= -\frac{1}{2\zeta R_D} \sqrt{\frac{L}{C}} \left(\frac{\Delta R_D}{R_D} \right) + \frac{1}{4R_D \zeta} \sqrt{\frac{L}{C}} \left(\frac{\Delta L}{L} \right) - \frac{1}{4\zeta R_D} \sqrt{\frac{L}{C}} \left(\frac{\Delta C}{C} \right) \\ &= \left[-2 \left(\frac{\Delta R}{R_D} \right) + \left(\frac{\Delta L}{L} \right) - \frac{\Delta C}{C} \right] \frac{1}{4\zeta R_D} \sqrt{\frac{L}{C}} \end{aligned}$$

$$\frac{\Delta |\zeta|}{|\zeta|} = \left[\left| \frac{\Delta R}{R_D} \right| + \frac{1}{2} \left| \frac{\Delta L}{L} \right| + \frac{1}{2} \left| \frac{\Delta C}{C} \right| \right] \frac{1}{2\zeta R_D} \sqrt{\frac{L}{C}} \quad 010$$

$$\frac{\Delta |\zeta|}{|\zeta|} = \left[\left| \frac{\Delta R}{R_D} \right| + \frac{1}{2} \left| \frac{\Delta L}{L} \right| + \frac{1}{2} \left| \frac{\Delta C}{C} \right| \right]$$

Percent change of $|\zeta| \propto$ percent change of $R_D, L, C.$
e.g., 5% change in components could cause a

$$\frac{\Delta |\zeta|}{|\zeta|} = [5\% + \frac{1}{2} 5\% + \frac{1}{2} 5\%]$$

$$\frac{\Delta |\zeta|}{|\zeta|} = 10\% \text{ change in damping factor.}$$

This also implies using 5% damping resistors could cause a worse case of 5% change in damping factor.

The following two families of curves are standard second order response with various damping factors. The one on the left is in frequency domain and the other one is in time domain.

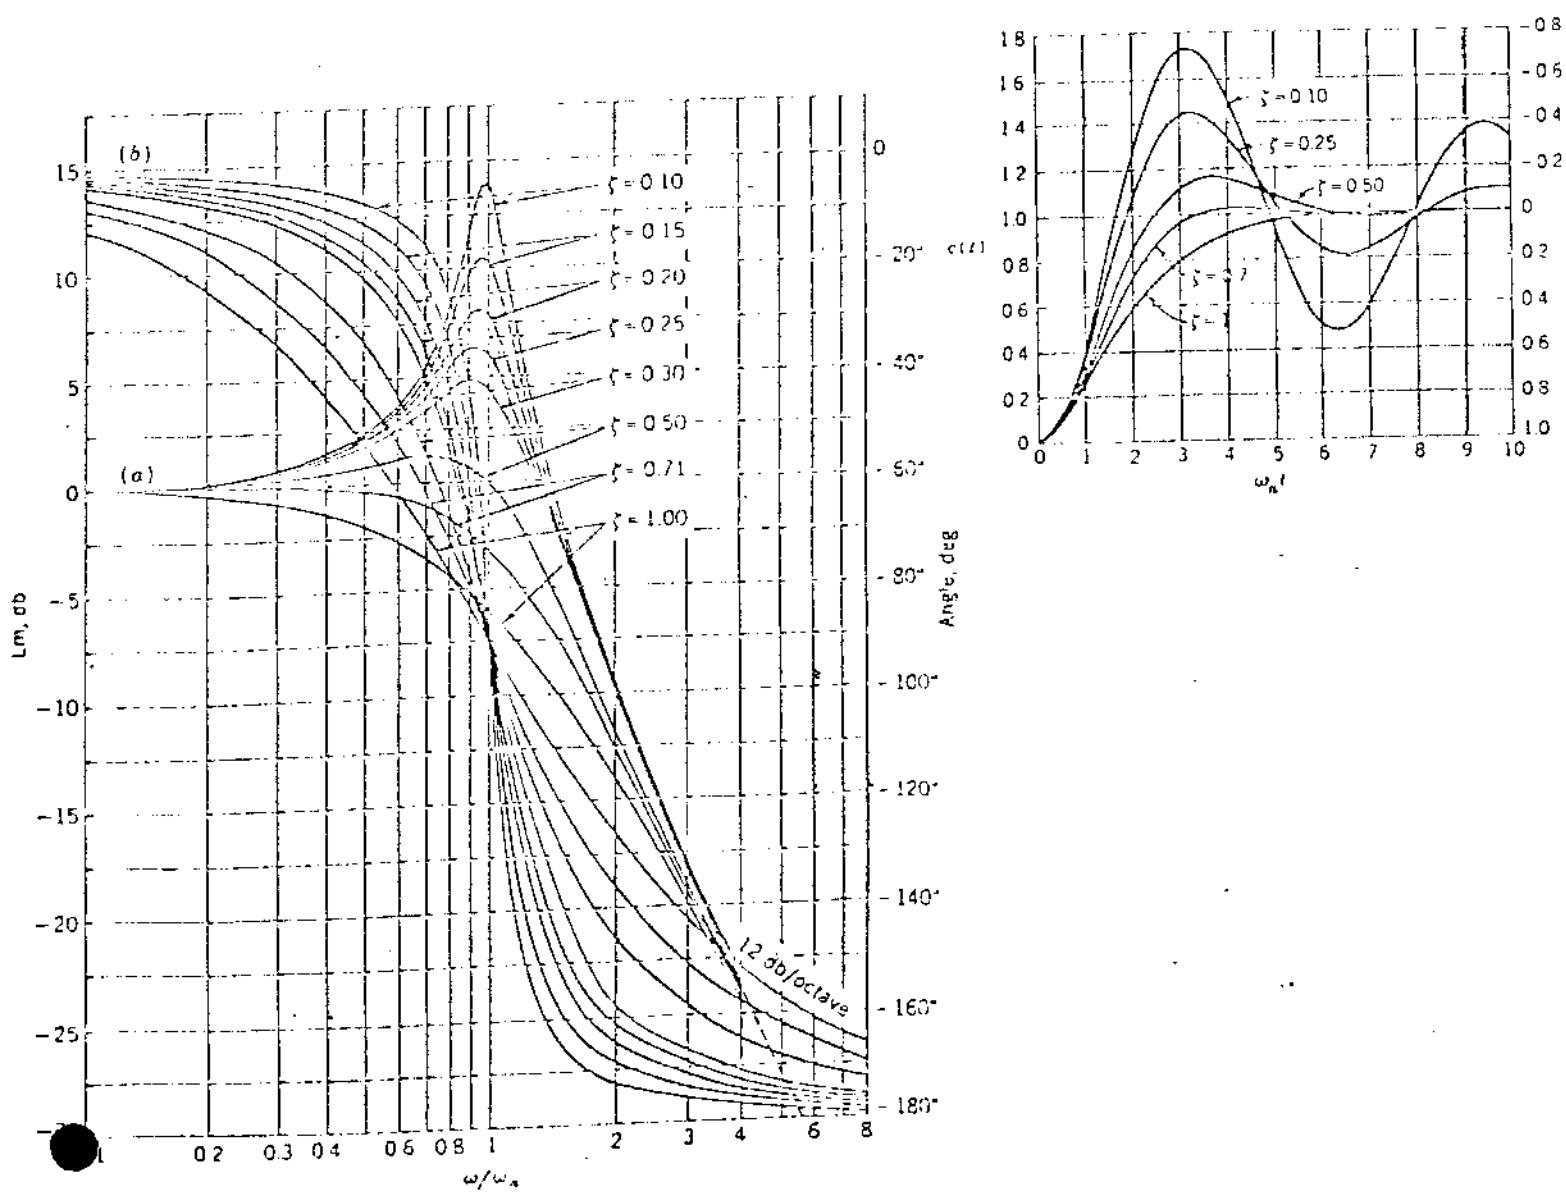

FIGURE 3-4
Log magnitude and phase diagram for

$$\left[1 + \frac{j2\zeta\omega}{\omega_n} + \left(\frac{j\omega}{\omega_n} \right)^2 \right]^{-1}$$

III. READ CHIP--AMPLIFIER PORTION

The read chip is an eighteen-pins LSI chip. (See Shugart ES 30064-0 & Mot. MC3470). The chip basically consists of three separate portions--amplifier, differentiator and time-domain filter and digitizer. Each portion will be discussed separately in a logical order so as to preserve the flow of read chain signals.

1. AMPLIFIER GAIN CALCULATION:

The amplifier is a two-stage amplifier with gains equalled to:

$$A_0 = A_1 \cdot A_2$$

$$A_1 = \frac{2 \times (2500)}{240 + 2r_e}$$

$$= 10 \Omega$$

r_e = Transistor internal
emitter resistance

$$A_2 = \frac{2(3226)}{580 + 2r_e} = 8.6$$

$$\approx \frac{26 \text{ mV}}{200 \mu\text{A}}$$

$$= 130 \Omega$$

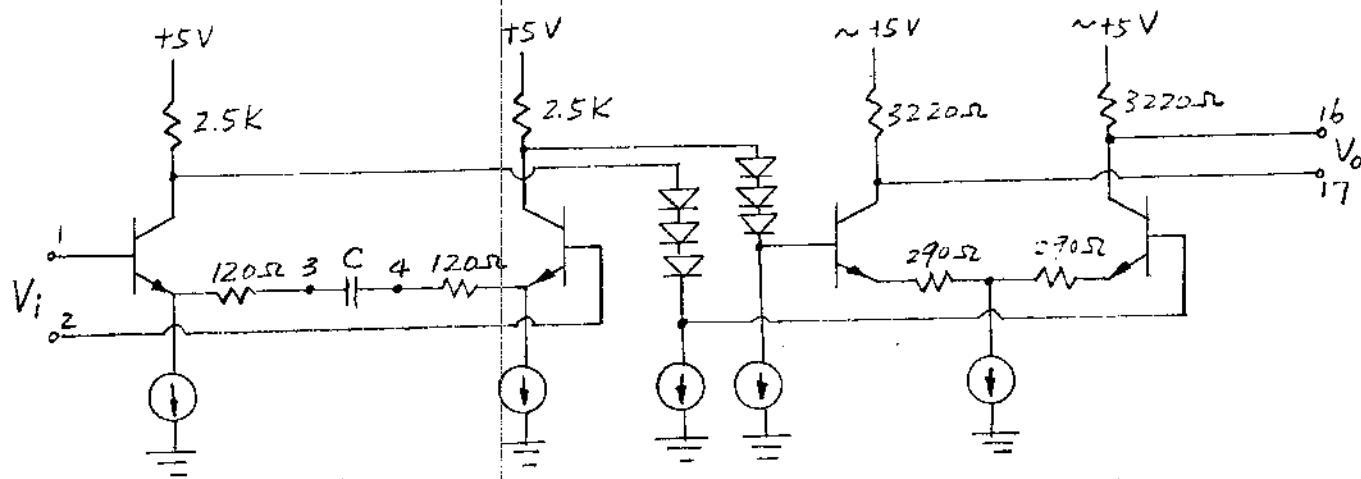

$$A_0 = 86$$

$$\approx 100$$

$$r'_e \approx \frac{26 \text{ mV}}{300 \mu\text{A}}$$

$$= 87 \Omega$$

**The Motorola LSI Process Variation, according to the designer--Mike Henry, usually resulted in values of average gain higher than calculated. The average is usually around 100.

Simplified schematic of MC3470, amplifier portion.

2. TRANSFER FUNCTION:

Due to the fact that the transistor parameters are not given, the band-width of the amplifier cannot be calculated. I shall use the guaranteed minimum device band-width for analysis purposes. From actual tests (See Appendix B), the minimum band-width of the amplifier is more than 5 MHZ.

$$T(s) = \frac{A_1 \cdot A_2 \cdot W_B}{s + W_B}$$

$$= \frac{10 A_1 W_B}{s + W_B}$$

$$W_B = \text{Min. band-width}$$

$$= 2\pi \times 5 \times 10^6 \text{ Hz}$$

The gain of the first stage is affected by the D.C. blocking capacitor.

$$A_1 = \frac{2(2500)}{R + \frac{1}{SC}}$$

$$R = 2(120) + 2 \times \left(\frac{26 \times 10^{-3}}{200 \times 10^{-6}} \right) \approx 500 \Omega$$

$$A_1 = \frac{500 SC}{500 SC + 1}$$

$$T(s) = 10 \cdot \frac{\frac{500 SC W_B}{500 SC + 1}}{s + W_B}$$

$$= \frac{100 SW_B}{(s + W_B)(s + \frac{1}{500C})}$$

From the transfer function, it is obvious that the high frequency corner of the amplifier is determined by W_B while the low frequency corner is determined by the value of the capacitor & the internal resistance. If we do not have to worry about read/write recovery, then the capacitor can be chosen such that

$$\frac{1}{WC} = \frac{R}{100}$$

W = the lowest frequency we want to pass

e.g. $W = 2\pi$ (62.5 KHz)

$R = 500 \Omega$ (Fixed)

$C \approx .47 \mu F$

This number can be varied to suit different requirements

3. D.C. BLOCKING CAPACITOR:

The capacitor is necessary at gain-stage #1 of the read amplifier to prevent gain-stage #2 from saturating due to D.C. offset from stage #1. A problem arises after insertion of the capacitor. That is, during write mode, the capacitor will be AC charged to a worse case of 5V P-P which will affect the read/write recovery time. It was determined empirically (visually) that read/write recovery time equals to $100\mu\text{s}$ for SA 450 and $50\mu\text{s}$ for SA 850. This amounted to two time constants for SA 450 and four time constants for SA 850.

$$\begin{aligned} C &= \frac{\text{R/W Recovery time}}{XR} & X = \text{Number of time constants} \\ &= \frac{50\mu\text{s}}{4 \times 500} \\ &= 0.025\mu\text{f} & (\text{SA850}) \end{aligned}$$

$$\begin{aligned} C &= \frac{100\mu\text{s}}{2 \times 500} \\ &= 0.1\mu\text{f} & (\text{SA 450}) \end{aligned}$$

See Appendix B for the exponential decaying of amplitude versus time constant plot.

4. AMPLIFIER SATURATION:

The read amplifier begins to show distortion if the input exceeded 28mV (P-P). With a nominal gain of 100, the output would be 2.8 V (P-P). When input reaches 35 mV, the amplifier breaks down completely. We are currently operating at an input voltage of less than 15 mV (P-P) which is in the linear region. (See Appendix B for the saturation plot).

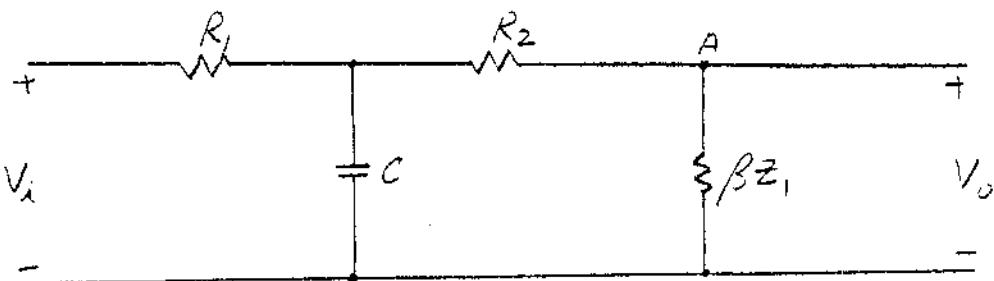

A rough estimation from the read circuit shows that the read output pins are sitting at +3V. This tells us that the output cannot exceed 2V (O-P). This agrees with what was observed.

IV. IBM FILTER (SA 850 ONLY)

The so-called IBM filter is actually a jumper selectable "all pass" filter or "low pass" filter. When the "F" jumper is "IN", a ground is provided to the circuit, the filter becomes a single pole low pass filter. When "F" jumper is "OUT", the filter becomes a single pole all pass filter.

1. SINGLE POLE LOW PASS FILTER

The equivalent circuit of the single pole low pass is:

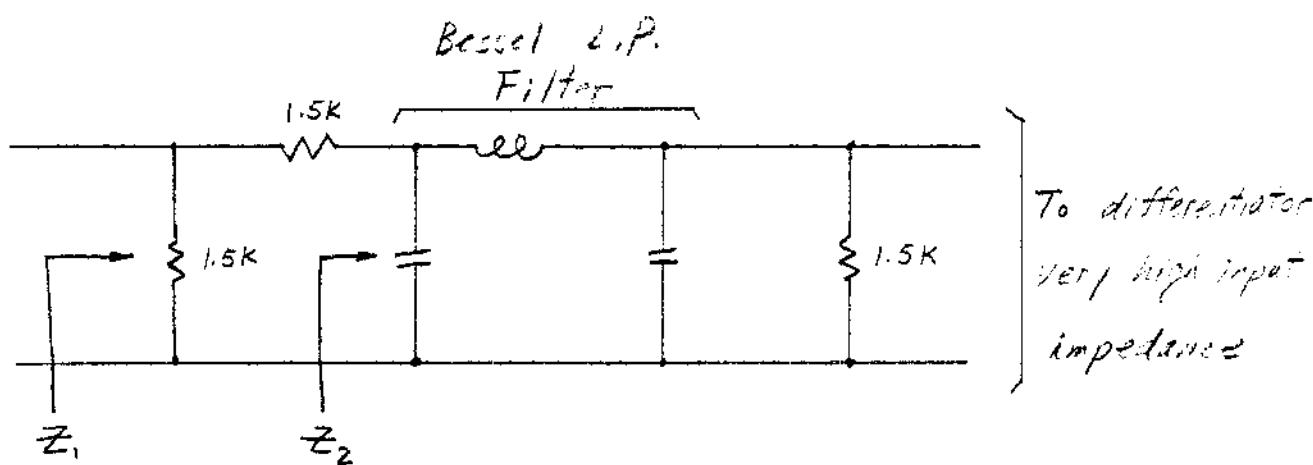

Point A is the emitter of either transistors (8B, pin 10 or 8) on the schematic of SA 850.

Z_1 is the parallel impedance of 1.5K ohm and $1.5k \text{ ohm} + Z_2$.

Z_2 is the input impedance of Bessel filter.

Beta is the forward current gain of the transistors.

To evaluate the change of impedance Z_1 to the response of the L.P. network and for simplicity without losing accuracy, I am using piece wise linear approach by assuming:

$$Z_2 = 1.5K \quad (\text{in passband})$$

$$Z_2 = 0 \quad (\text{in stopband})$$

$$Z_1 = 1.5k \quad (1.5K+1.5K)=1K \quad (\text{pass band})$$

$$Z_1 = 1.5k \quad 1.5K = .75K \quad (\text{stop band})$$

$$\beta \geq 100$$

$$R_1 = 1k \text{ ohm}$$

$$R_2 = 1k \text{ ohm}$$

$$\beta(1K\Omega) \text{ or } \beta(.75K\Omega) \gg 1K$$

This means that the impedance changes will not have a drastic effect on the network under study. This is an important point to note when we are trying to calculate the transfer function and response of the network in Appendix C. It simplifies the matter a lot.

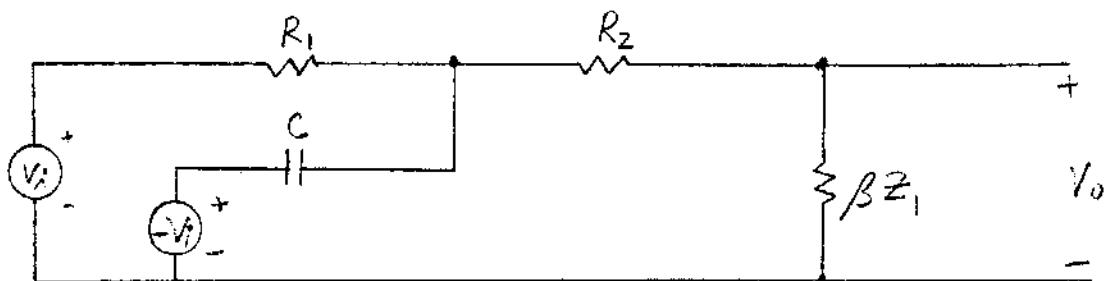

The transfer function of the original network as calculated in Appendix C is:

$$T(s) = \frac{1}{CR_1} \left(\frac{1}{s + \frac{1}{CR_1}} \right) \quad (\beta Z_1 \gg R_1, R_2)$$

This is a typical single pole low pass network. Its responses are plotted in Appendix C with various C's and R_1 's.

2. SINGLE POLE ALL PASS FILTER:

The equivalent circuit is:

The transfer function of this network (see Appendix C) is:

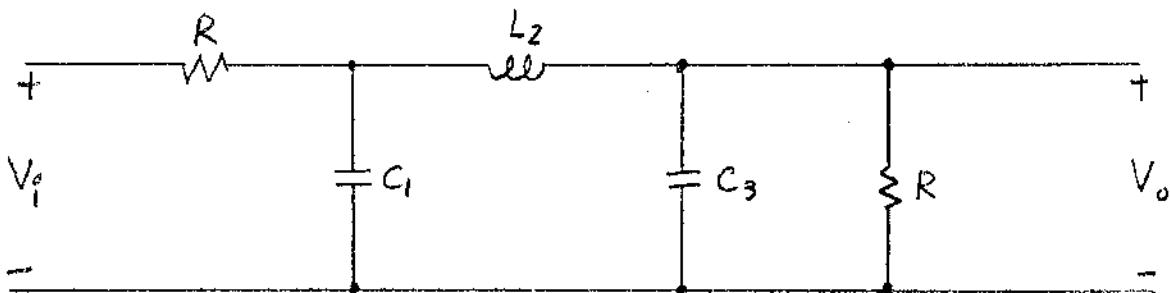

$$T(s) = \frac{1 - SCR_1}{1 + SCR_1} \quad ; \quad T(j2\pi f) = \angle -2 \tan^{-1} 2\pi f CR_1$$

It is obvious that the network is used for phase compensation. The amplitude is unity. The responses of this network are plotted in appendix C with various values of C and R.

V. LOW PASS BESSSEL FILTER

The filter was used for its superior linear phase characteristics. See memo to Roger Stromsta on 8-7-79 on the filter.

The transfer function of the third order filter is:

$$T(s) = \frac{1}{s^3 R C_1 C_3 + s^2 L_2 (C_1 + C_3) + s (R(C_1 + C_3) + \frac{L_2}{R}) + 2}$$

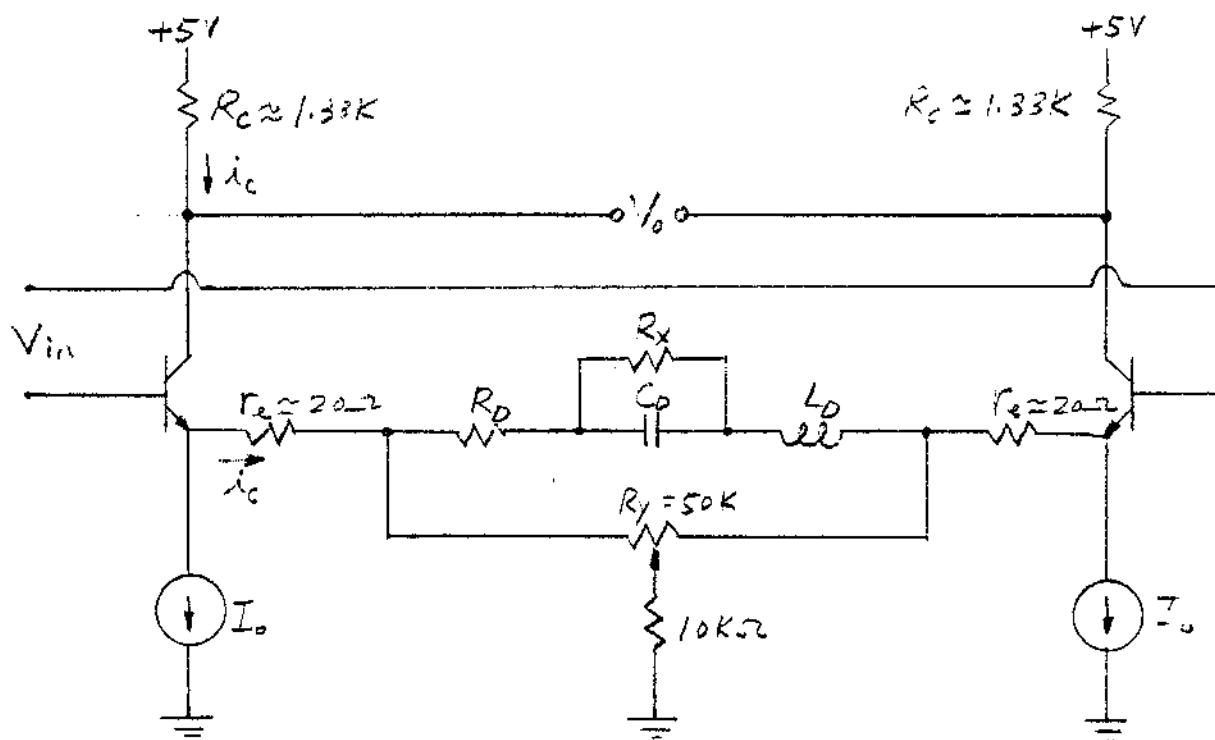

The filter being used for the current SA 850 is a standard 3 pole L.P. Bessel filter with proper scaling. The one being used for the SA 450 is a modified 3 pole L.P. Bessel with C_3 changed from standard 47 pf to 100 pf for high frequency compensation.

The actual frequency response plots of the SA450 do indicate that the standard elements LP filter has a more linear phase characteristics than the adjusted one.

VI. READ CHIP--DIFFERENTIATOR PORTION

1. OVERALL DESCRIPTION:

For a complete description of the differentiator, please read Motorola's ML3470 specification and application note. The following is a brief description of the differentiator. There are two 0.1 micro-farad capacitors at the input of differentiator. They are there to prevent any D.C. level imbalance on the line which would upset (saturate) the input stage of the differentiator.

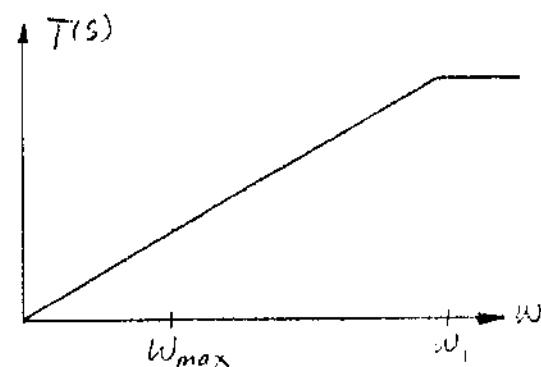

$$V_o = 2R_c i_c$$

For a simple differentiator

$$R_0 = 0, R_x = \infty, L_0 = 0, R_y = \infty$$

$$\therefore i_c = C \frac{dV_i}{dt}$$

$$\therefore V_o = 2R_c C_0 \frac{dV_i}{dt}$$

Simple ideal differentiator

ω_{max} = Max. operating freq.

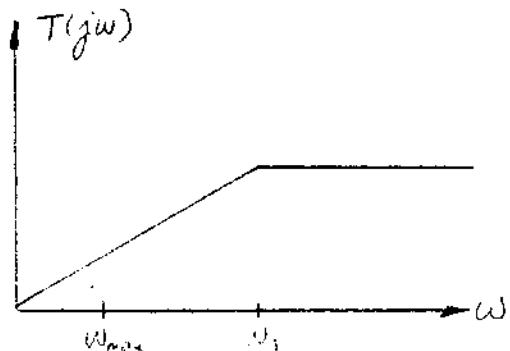

$$\omega_c = Pole = \frac{1}{2i\pi C_0}$$

R_D is introduced to ensure the phase linearity of the differentiator and to limit the noise band-width where

$$10\omega_{max} = \frac{1}{C_0(2f_e + R_D)}$$

$$\omega_i = 10\omega_{max}$$

$$R_D = \frac{1}{10\omega_{max} C_0} - 2f_e \quad \text{--- (1)}$$

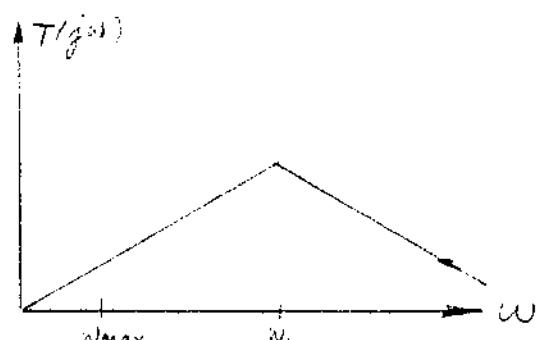

Differentiator whose pole is affected by R_D .

L_D is introduced to create another pole to further reduce the noise band-width:

$$\omega_i = 10\omega_{max}$$

$$= \frac{1}{\sqrt{L C_0}}$$

$$L_D = \frac{1}{100(\omega_{max})^2 C_0} \quad \text{--- (2)}$$

Differentiator where another pole is added

C_D is determined such that under maximum input voltage, the current source will not be saturated. That is,

$$C_0 = \frac{I_{max}}{A_{max} E_{max} \omega_{max}} \quad \text{--- (3)}$$

$$I_{max} \approx 1mA$$

$$A_{max} = \text{Max. amplifier gain} \\ = 120$$

$$E_{max} = \text{Max. ideal output} \\ \leq 15mV (p-p)$$

$$\omega_{max} = \text{Max. frequency} = 2\pi \times 250\text{kHz} \quad (29.7) \\ = 2\pi \times 125\text{kHz} \quad (29.7)$$

R_Y is there to null the current imbalance in the differentiator and to compensate for offset voltage in the digitizer portion. By varying R_Y , the internal asymmetry of the device can be eliminated.* Under A.C. analysis, the resistor R_Y can be ignored.

R_X is added to control the location of zero of the transfer function. This zero is adjusted so as to cancell out the pole created by the D.C. blocking capacitor in the amplifier portion as discussed earlier. In other words, we want to adjust R_X to improve the overall system low frequency linearity.

$$\therefore \text{Pole created by D.C. capacitor} = \frac{1}{RC}$$

$$\frac{1}{RC} = \frac{1}{C_D R_X}$$

$\underbrace{}$ zero of differentiator

$$\therefore R_X = \frac{500C}{C_D} \quad \text{--- (4)}$$

There are two capacitors at each of the read chip's D.C. power inputs. The power inputs are +24 V and +5 V for SA850 and +12 V and +5 V for SA450. The capacitors are there for power line noise filtering. For SA850, there is an additional +12 V zener diode CR11 which is for generating +12 V on board.

* Assumption was made here that the supply voltages and input voltage remain constant. Otherwise, asymmetry can still occur.

2. TRANSFER FUNCTION:

The transfer function without R_x is : (See Appendix E)

$$T(s) = \frac{R_c}{L_D} \cdot \frac{s}{s^2 + s \frac{(2R_e + R_D)}{L_D} + \frac{1}{L_D C_D}}$$

With R_x :

$$T'(s) = \frac{R_c}{L_D} \cdot \frac{\left(s + \frac{1}{C_0 R_x}\right)}{s^2 + s\left(\frac{1}{C_0 R_x} + \frac{R_D + 2R_e}{L_D}\right) + \frac{1}{L_D C_D}}$$

Note the zero location has changed
Transfer function for the amplifier:

$$T''(s) = \frac{100s\omega_B}{(s + \omega_B)(s + \frac{1}{R_C})}$$

Since this is a linear system, the total transfer function is :

$$T(s) = T'(s) \cdot T''(s) \\ = \frac{R_c}{L_D} \cdot \frac{\left(s + \frac{1}{C_0 R_x}\right)}{s^2 + s\left(\frac{1}{C_0 R_x} + \frac{R_D + 2R_e}{L_D}\right) + \frac{1}{L_D C_D}} \cdot \frac{100s\omega_B}{(s + \omega_B)(s + \frac{1}{R_C})}$$

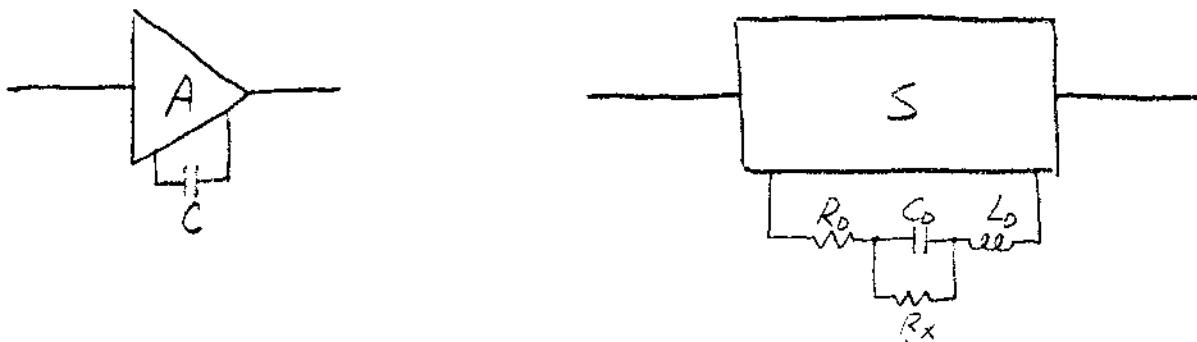

With perfect pole/zero cancellation:

$$T(s) = \frac{100R_c s\omega_B}{L_D} \cdot \frac{1}{\left(s^2 + s\left(\frac{1}{C_0 R_x} + \frac{R_D + 2R_e}{L_D}\right) + \frac{1}{L_D C_D}\right)\left(s + \omega_B\right)}$$

The responses of the differentiator before and after pole/zero cancellation are plotted in Appendix E.

3. COMPONENT SELECTION:

The following components are selected under ideal and theoretical conditions. They are selected and their responses are plotted for the purpose of comparison with the actual values used on the devices.

$$C = 0.025 \mu F \quad (\text{SA 850})$$

$$C = 0.1 \mu F \quad (\text{SA 450})$$

$$C_o = \frac{i_{c(\max)}}{A_{\max} E_{\max} \omega_{\max}} \quad (\text{From eqn. #3})$$

$$= \frac{1 \times 10^{-3}}{(120)(15 \times 10^{-3})(250 \times 10^3)}$$

$$C_o = 353 \text{ pf} \quad (\text{SA 850})$$

$$C_o = \frac{1 \times 10^{-3}}{(120)(15 \times 10^{-3})(125 \times 10^3)}$$

$$C_o = 707 \text{ pf} \quad (\text{SA 450})$$

$$R_D = \frac{1}{10 \omega_{\max} C_o} - 2 R_e \quad (\text{From eqn. #1})$$

$$= \frac{1}{10 (2\pi 250 \times 10^3) (330 \times 10^{-12})} - 40 \Omega \quad \text{standard value used}$$

$$R_D = 153.2 \quad (\text{SA 850})$$

standard value

$$R_D = \frac{1}{(10)(2\pi \times 125 \times 10^3)(680 \times 10^{-12})} = 40\Omega$$

$R_D = 147\Omega$
(150Ω)

↑
 $(SA 450)$ Standard value used
 $Standard\ value$

$$R_x = \frac{RC}{C_D} \quad (From eqn. #4)$$

$$= \frac{500 \times 0.027 \times 10^{-6}}{330 \text{ pF}}$$

$R_x = 40.1 \text{ k}\Omega$
$(SA 850)$

$$R_x = \frac{500 \times 0.1 \times 10^{-6}}{680 \times 10^{-12}}$$

$R_x = 73.5 \text{ k}\Omega$
$(SA 450)$

$$L_D = \frac{1}{100(\omega_{max})^2 C_D} \quad (From eqn. #2)$$

$$= \frac{1}{100(2\pi \times 250 \times 10^3)^2 \times 330 \times 10^{-12}}$$

$L_D = 12.3 \mu\text{H}$
$(12 \mu\text{H})$

$(SA 850)$
(Standard value)

$$L_D = \frac{1}{100(2\pi \times 125 \times 10^3)^2 \times 680 \times 10^{-12}}$$

$L_D = 23.8 \mu\text{H}$
$(22 \mu\text{H})$

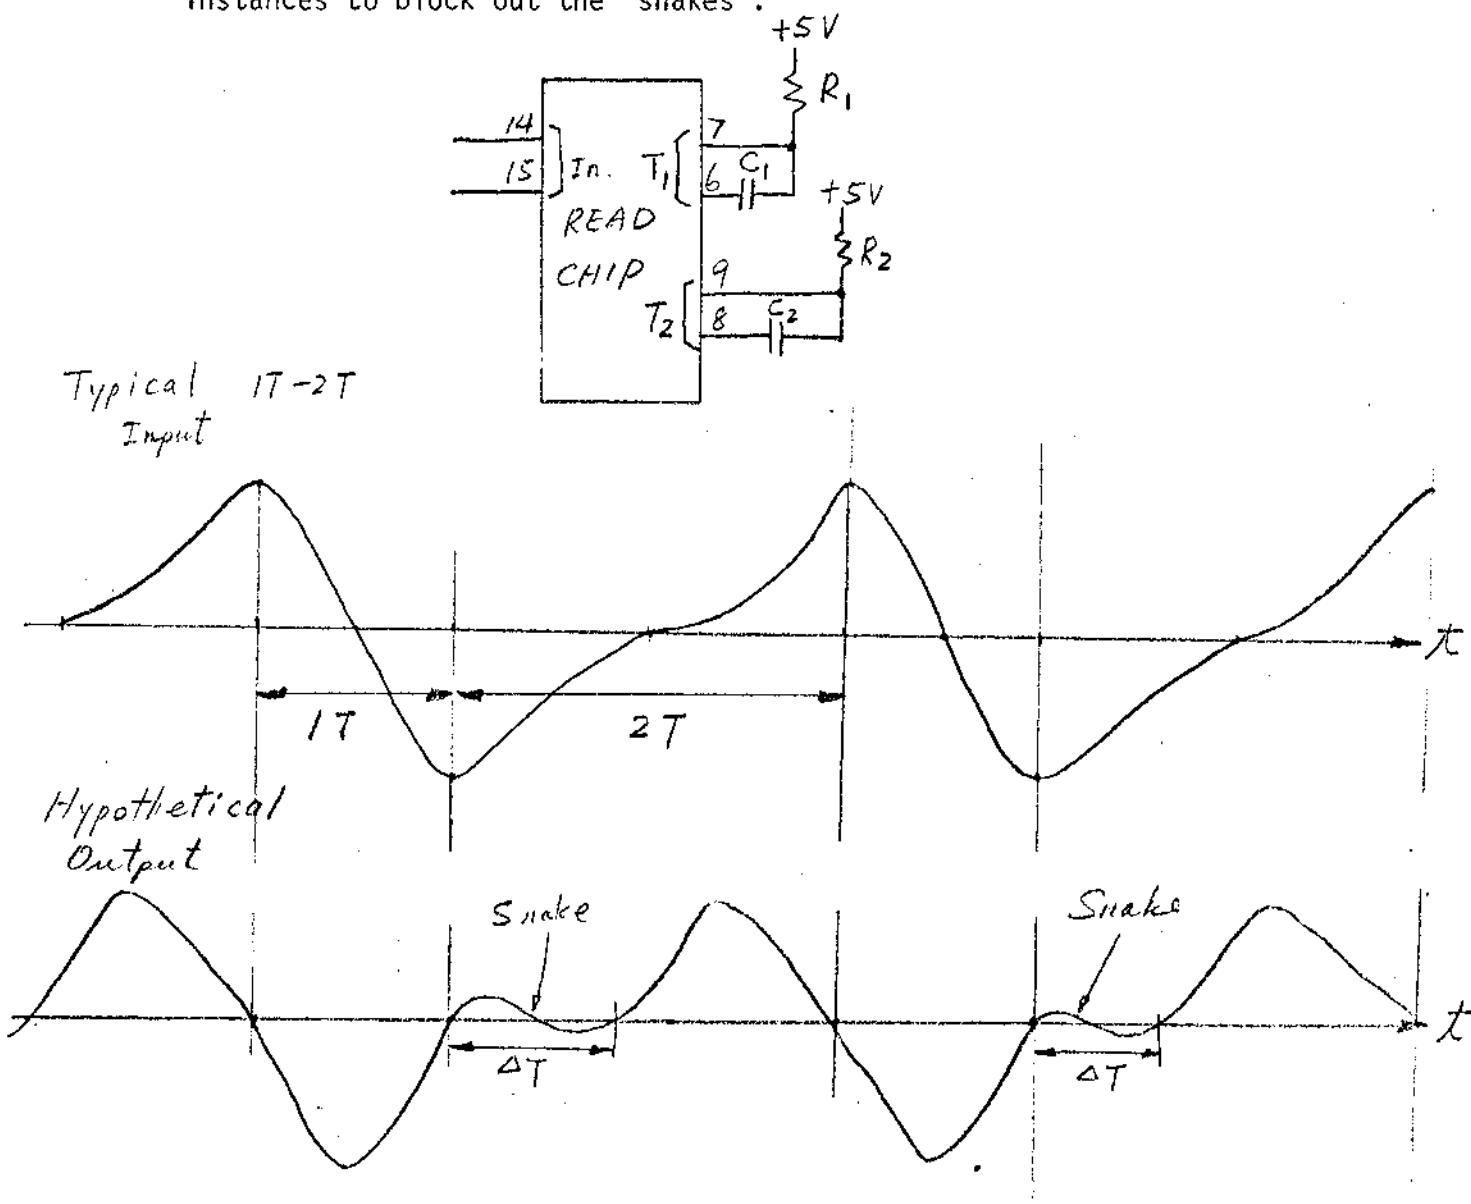

$(SA 450)$
(Standard value)

Frequency response and time response plot of the actual values and the ideal (optimum) values are shown in Appendix E. As revealed from the plots, the frequency response curves (no perfect pole/zero cancellation) with optimum elements do look better than the response curves with actual values--currently in use on our drives. Furthermore, by assuming a perfect pole/zero cancellation, the frequency response of the actual value curves improved substantially at low frequency while the optimum value curves did not show much of a difference. The time domain response plots do indicate less phase delay in the optimum case than the actual. These time domain plots are assuming a steady state conditions. One thing that is interesting to note is that in the case of perfect pole/zero cancellation, the steady-state phase delay remains the same--no improvement.

VII. READ CHIP-- TIME DOMAIN FILTER AND DIGITIZER

1. TIME DOMAIN FILTER AND BIT PULSE WIDTH:

The filter is necessary because the actual signal from our read/write head is not a sinewave. It is more like Gaussian curves superimposed on each other and plus the system noise. The differentiated signal would not be a pure cosine wave. It would have "snakes" on the differentiated signal. This would mean that extra bit would be generated if these "snakes" were not being filtered. The time domain filter behaves like a window where it opens up at some instances and closed at other instances to block out the "snakes".

If the time domain filter had effectively blocked out the snakes, then the differentiator and the zero-crossing comparator in the chip would behave like a peak detector and data bit would be regenerated. Period T_1 determines effectively how much we want to block and period T_2 determines the pulse width of the regenerated bits. The periods are determined

$$T_1 > \Delta T$$

$$T_1 < \frac{1}{3}(2T)$$

Under the worst case situation:

$2T$ is assumed to be the longest period in MFM encoding.

$$\Delta T \leq \frac{4\mu s}{3} \quad (\text{SA } 250) \quad 2T = 4\mu s \quad (\text{SA } 250)$$

$$\ll \frac{8\mu s}{3} \quad (\text{SA } 450) \quad = 8\mu s \quad (\text{SA } 450)$$

If ΔT ever gets greater than $1/3 (2T)$, the time domain filter would not be effective. Bit error would occur!

Without going into any further details, it is obvious that the optimum T_1 (assuming symmetrical signal) should be:

$$T_1 \approx \frac{1}{3}(2T)(1 - \sqrt{\text{Device time variance}})$$

$$= 1133 \text{ ns} \quad (\text{SA } 250)$$

$$= 2267 \text{ ns} \quad (\text{SA } 450)$$

Optimum theoretical values

$$T_1 = (R, C, \times 0.625) + 200 \text{ ns} \quad (\text{See Sec. 6})$$

$$= 969 \text{ ns} \quad (\text{SA } 250)$$

$$= 1250 \text{ ns} \quad (\text{SA } 450)$$

Actual values used on
Chauvin boards.

There are three constraints which have to be met for the time domain filter to work:

- (1) $\Delta T < \frac{1}{3}(2T)$ (snake cannot be big)
- (2) ΔT pulse is near center
- (3) $T_1 > \Delta T$

The aforementioned criteria is not critical for our current SA 850/450 operations. We have a lot of margin to play with at this point. However, in the future, if we intend to increase bit density with the same chip, problems may arise.

$$T_2(\text{Pulse width}) = R_2 C_2 \times 0.625 \quad (\text{see Spec.})$$

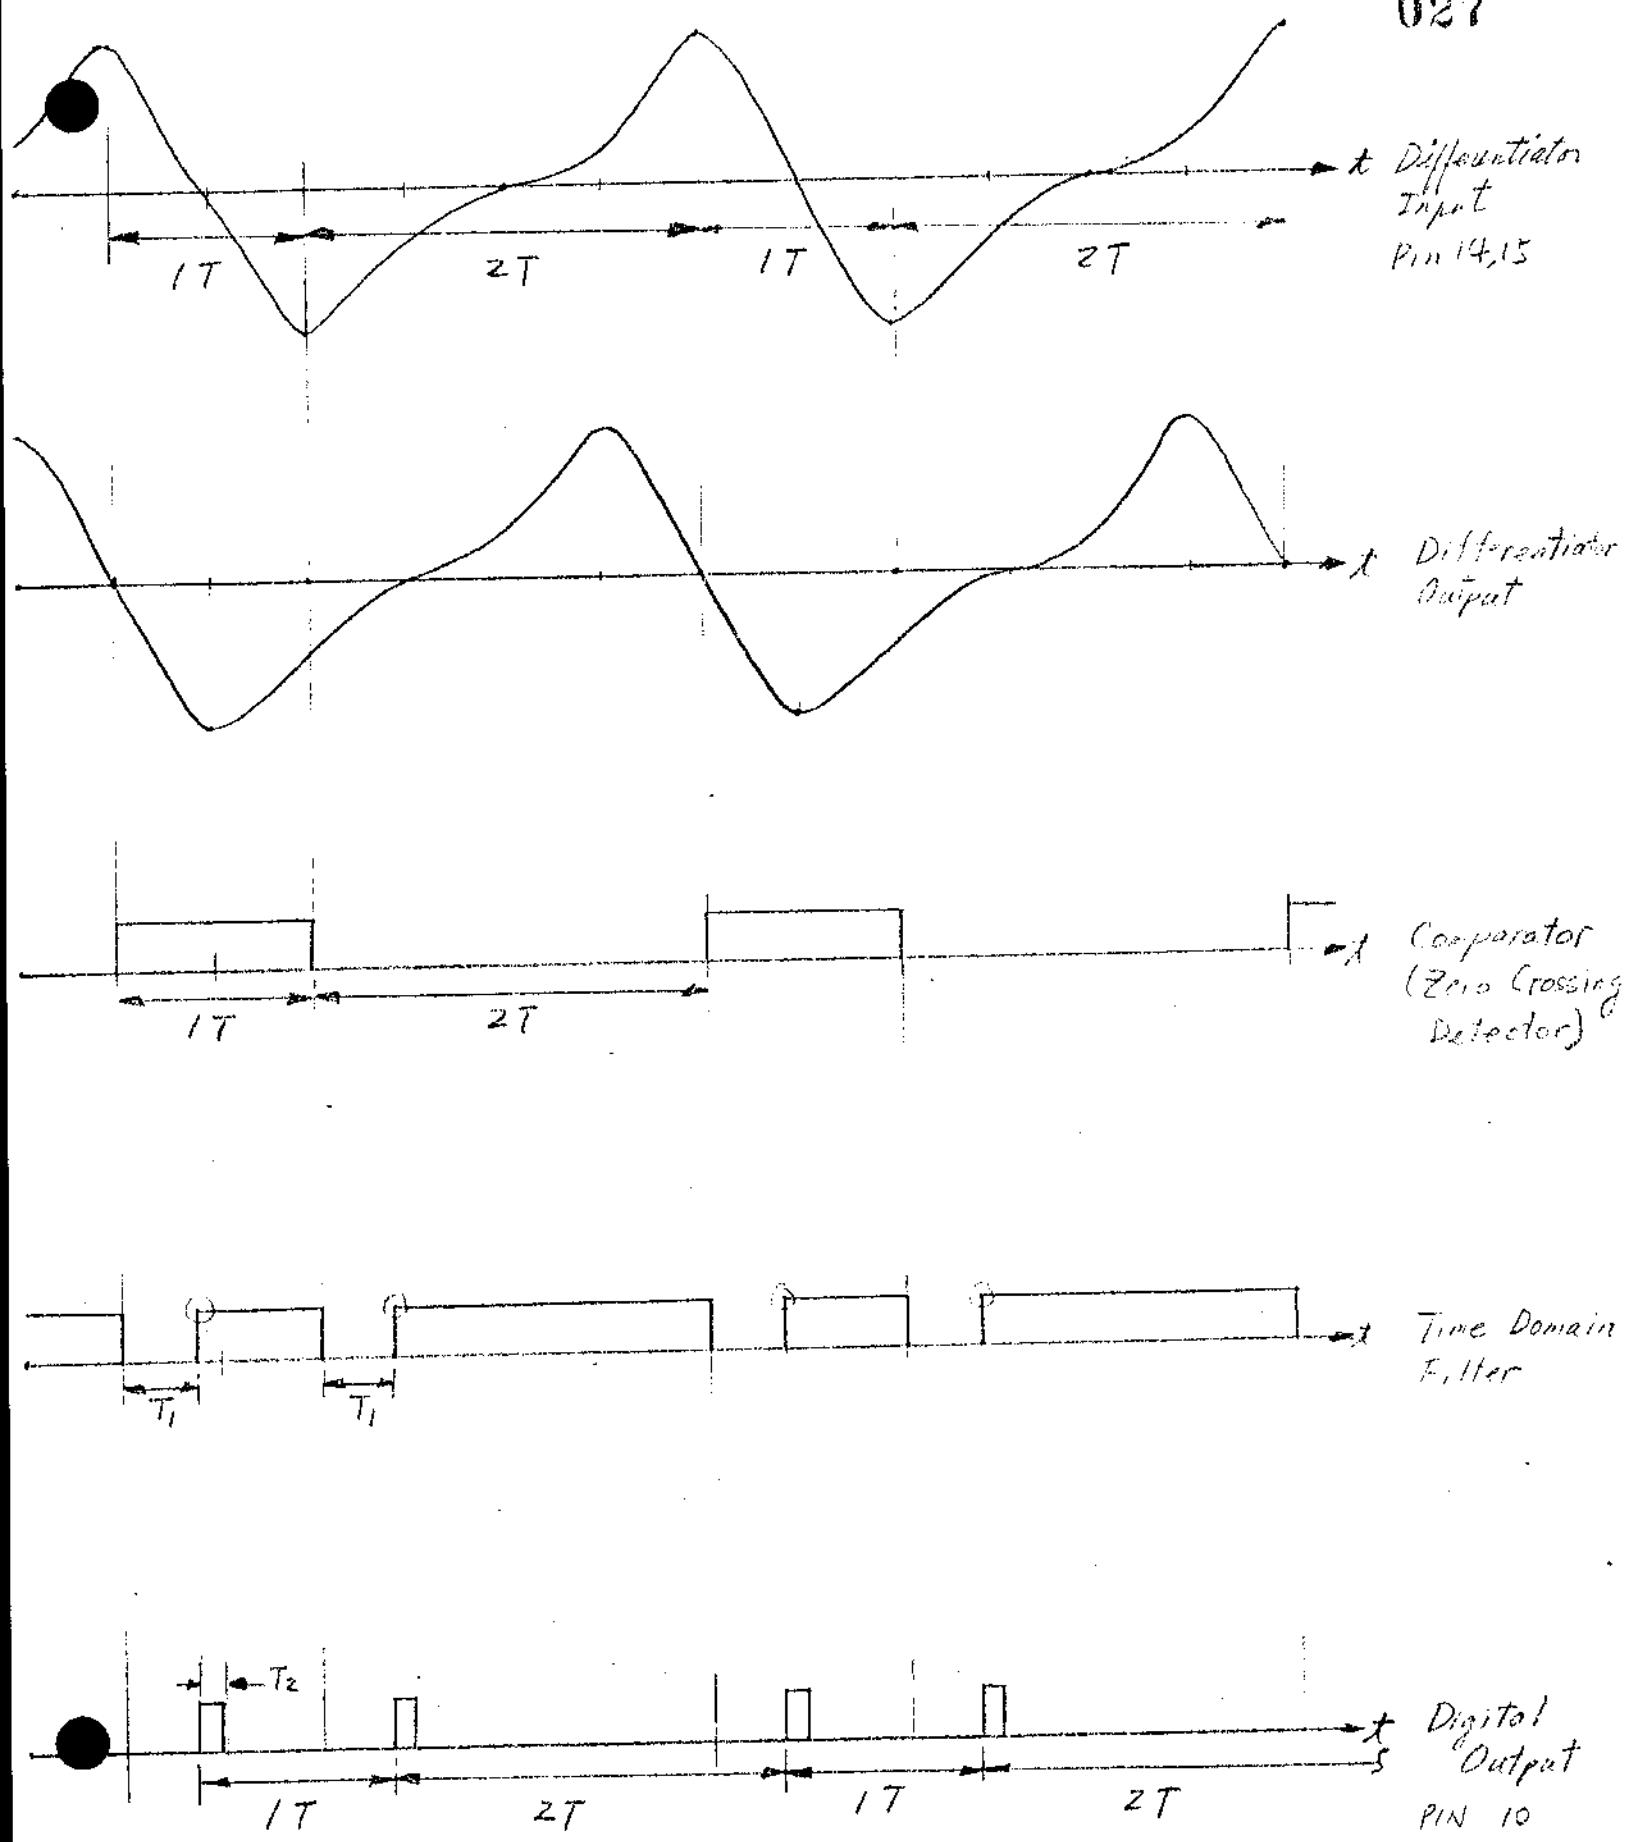

T_2 is not critical as long as it is wide enough to provide enough hold time for TTL circuit. Minimum of 100 nano seconds is sufficient. Current value of T_2 for SA 850 is 200 nS, for SA 450 is 1.05 μ s.

2. DIGITIZER:

It consists of basically a comparator, one shot and a D-flip flop. Together they convert the analog input signal which contains the data into a series of digital pulse train. Then the digitized information (bits) can be processed by the host system (computer). The digital output is being time delayed by an amount T_1 , which is the time domain filter window width.

The following sketch show a hypothetical and ideal case of how an analog signal is being converted into digital information.

027

IIX. CONCLUSION:

This read chain analysis by no means is "the analysis" to determine the system parameters. It is extremely unlikely for anyone to come up with a perfect working system from paper work calculation and modeling. A lot of changes have to be made by an experienced system designer judging from overall system performance to perfect the design. However, this analysis does provide a complete explantion of individual functions of the read chain and also provides a quantitative way (guideline) of selecting components. Any major deviation from the calculation should probably be backed up with logical explantions from the original designer.

In general, the experiments agreed very well with simulated plots in the pass band. The original goal of this assignment was to put in writing how each individual blocks of the read chain functioned. The time expection and the original goal of this assignment making it not feasible at this point to delve into other related questions. They are as follows:

1. Actual impacts of IBM filter on phase performance.
2. Is the low pass Bessel filter necessary at all and how does it affect our phase margin?
3. What is the amount of phase jitter introduced by the read chip?
4. The noise level of the read chain.
5. Electromagnetic interference susceptibility of our drives.

Some of these questions can be answered quite easily, with time availability, by taking the analysis done here one step further. Others require a completely different approach to get to the answer.

A similar analysis on write chain, which is supposedly to be completed at the same time, will most likely ready in about a week.

IX. ACKNOWLEDGEMENTS:

I am grateful to both Art Geffon and Dick Freytag for their kind advise and suggestions. Also, it would have been impossible to complete this analysis in the given amount of time without the help of Steve Downey in turning out those computer plots.

to sinewave input, assuming perfect pole/zero cancellation,
with actual and with optimum elements:

Same variations on elements as in #21,

P.194- P.204

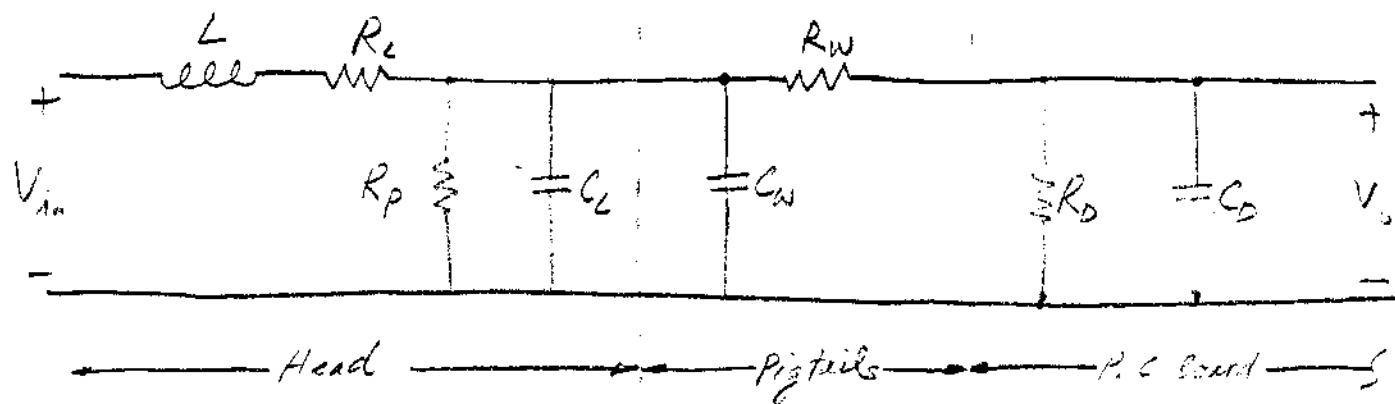

III. SET UP OF EXPERIMENTS:

The frequency response experiment was set up as following.

For the response of transformer and FET probe, please see reference #10. Their total responses are very linear. The experiment set up is not ideal because of number of jumpers and length of wires. For frequency beyond 5MHz, the results may not be accurate. The experiments were done to provide comparisons to the theoretical predictions. Accuracy is not the real object here. Accuracy here means $\pm 5\% - \pm 10\%$. However, within the pass band 50KHz - 300KHz, the responses are generally very accurate.

A-1. Derivation of read channel front end transfer function and related parameters

L = Head inductance

C_L = Head distributed capacitance

R_L = Head D.C. resistance

R_p = Head resistance at resonant

C_w = Pigtail equivalent capacitance

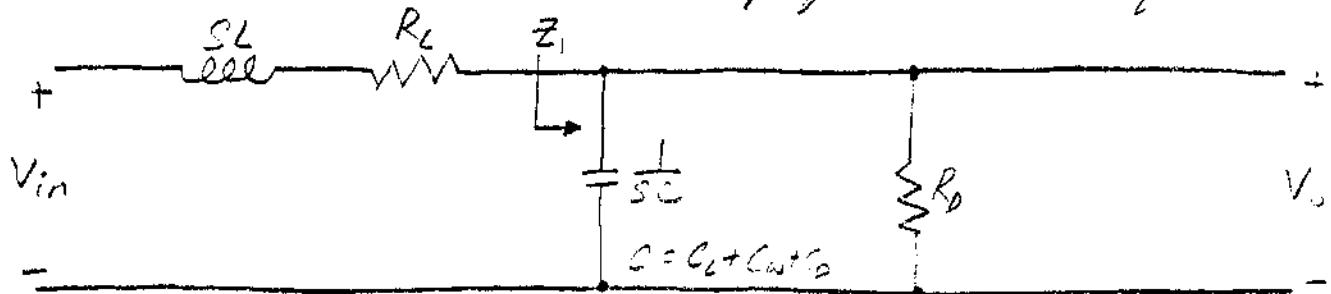

R_w = Pigtail D.C. resistance

R_d = Input damping resistance

C_o = Input capacitance of amplifier

$$\therefore R_w \approx 0 ; R_p \gg R_d$$

\therefore The circuit can be simplified and transformed to

$$\frac{V_o}{V_{in}} = \frac{1}{R_L + \frac{1}{LC}} = \frac{\frac{1}{LC} \cdot R_D}{\frac{1}{LC} + R_D}$$

$$= \frac{R_D}{SCR_D + 1}$$

$$\frac{V_o}{V_{in}} = \frac{\frac{R_D}{SCR_D + 1}}{SL + R_L + \frac{R_D}{SCR_D + 1}}$$

$$= \frac{R_D}{S^2 L C R_D + SL + S R_L C R_D + R_L + R_D}$$

$$T(s) = \frac{V_o}{V_{in}} = \frac{1}{LC \left[s^2 + s \left(\frac{R_L}{L} + \frac{1}{CR_D} \right) + \frac{R_L + R_D}{LC R_D} \right]}$$

$$\omega_0^2 = \frac{R_L + R_D}{LC R_D} \approx \frac{1}{LC} \quad (R_D \gg R_L)$$

$$f_0 = \frac{1}{2\pi} \sqrt{\frac{1}{LC}}$$

$$2f = \left(\frac{R_L}{L} + \frac{1}{CR_D} \right) \approx \frac{1}{CR_D} \quad (\text{For current load } \frac{R_L}{L} \ll \frac{1}{CR_D})$$

$$|Z| \equiv \frac{1}{\omega_0} = \frac{1}{2\omega_0} \sqrt{\frac{L}{C}}$$

For current drives:

$$C_C + C_D \approx 50 \text{ pF} ; C_D < 10 \text{ pF}$$

$$R_D = 6.8K\Omega // 22K\Omega = 5.69K\Omega \quad (\text{SA } 750)$$

$$= 4.87K\Omega // 20K\Omega = 4K\Omega \quad (\text{SA } 400)$$

To find the amplitude and phase response

$$T(j\omega) = \frac{1}{LC} \cdot \frac{1}{-\omega^2 + j\omega(\frac{R_L}{C} + CR_0) + \frac{1}{LC}}$$

$$= \omega_0^2 \frac{1}{-\omega^2 + j\omega 2\zeta f_0 + \omega_0^2}$$

$$= A(\omega) e^{j\theta(\omega)}$$

$$A(\omega) = \omega_0^2 \frac{1}{(-\omega^2 - \omega_0^2)^2 + (2\zeta\omega_0\omega)^2}$$

$$A(\omega) = \sqrt{\frac{1}{(1 - \frac{\omega^2}{\omega_0^2})^2 + (\frac{2\zeta\omega_0\omega}{\omega_0})^2}}$$

$$A(2\pi f) = \sqrt{\frac{1}{(1 - \frac{f^2}{f_0^2})^2 + (\frac{2\zeta\omega_0}{f_0})^2}}$$

Amplitude response

$$\theta(\omega) = -\tan^{-1} \frac{2\zeta\omega}{\omega_0^2 - \omega^2}$$

The solution to the phase is a valid solution yet it is not in the form we like, e.g. the angle is bounded by $\pm \frac{\pi}{2}$. We would prefer a solution in another form which would produce a more familiar curve. ($90^\circ/\text{decade-pole}$)

From the original transfer function

$$T(s) = \frac{1}{LC} \cdot \frac{1}{s^2 + 2\zeta s + \omega_0^2}$$

$$\omega_0^2 = \frac{1}{LC}$$

ζ = damping factor

$$T(s) = \frac{1}{2c} \frac{1}{(s - \zeta + \sqrt{\zeta^2 - \omega_0^2})(s - \zeta - \sqrt{\zeta^2 - \omega_0^2})}$$

Since we are interested in underdamped systems, $\zeta < \omega_0$

$$\therefore T(s) = \frac{1}{2c} \frac{1}{(s + \zeta + j\sqrt{\omega_0^2 - \zeta^2})(s + \zeta - j\sqrt{\omega_0^2 - \zeta^2})}$$

$$T(j\omega) = \frac{1}{2c} \frac{1}{[j(\omega + \sqrt{\omega_0^2 - \zeta^2}) + \zeta][j(\omega - \sqrt{\omega_0^2 - \zeta^2}) + \zeta]}$$

$$\begin{aligned}\theta(\omega) &= -\tan^{-1} \frac{\omega + \sqrt{\omega_0^2 - \zeta^2}}{\zeta} - \tan^{-1} \frac{\omega + \sqrt{\omega_0^2 - \zeta^2}}{\zeta} \\ &= -\tan^{-1} \frac{\frac{\omega}{\omega_0} + \sqrt{1 - \frac{\zeta^2}{\omega_0^2}}}{|\zeta|} - \tan^{-1} \frac{\frac{\omega}{\omega_0} - \sqrt{1 - \frac{\zeta^2}{\omega_0^2}}}{|\zeta|}\end{aligned}$$

$$\boxed{\theta(2\pi f) = -\tan^{-1} \frac{\frac{f}{\omega_0} + \sqrt{1 - \frac{\zeta^2}{\omega_0^2}}}{|\zeta|} - \tan^{-1} \frac{\frac{f}{\omega_0} - \sqrt{1 - \frac{\zeta^2}{\omega_0^2}}}{|\zeta|}}$$

Phase response

Percentage of overshoot for a second order system
is (See ref. # 1, chapter 9)

$$\text{Overshoot \%} = \begin{cases} \left[\frac{1}{2\sqrt{1-\zeta^2}} - 1 \right] 100\% & |\zeta| < 0.707 \\ 2\% & |\zeta| > 0.707 \end{cases}$$

The signal doesn't peak at ω_0 for $|\zeta| > 0.1$

The signal peaks at

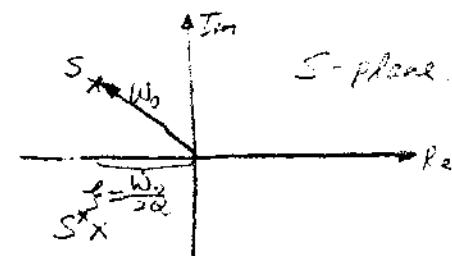

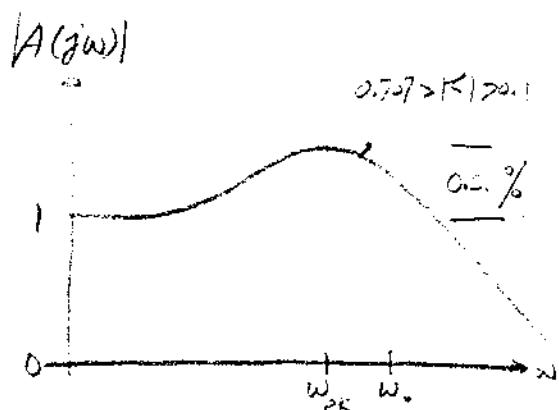

$$\omega_{\text{peak}} = \frac{\omega_0}{\sqrt{1-2\zeta^2}} \quad 0.707 > |\zeta| > 0.1$$

$$\approx \omega_0 \quad |\zeta| < 0.1$$

$$= 3\omega_0 \quad |\zeta| > 0.707$$

$$2\zeta \triangleq \frac{\omega_0}{Q}$$

$$|\zeta| = \frac{1}{2Q}$$

A-2. Linear phase analysis:

It is important to know what is the real meaning of linear phase and what criteria to use to achieve linear phase for a second order system. Second order system is important to most of network analysis because of all the relatively simple yet important characteristics exhibit by it. For a first order system, there is no self-resonant and hence no peaking can occur. This means that a first order system has to be overdamped and that there is not much change we can do to a first order system to alter its normalized phase and amplitude characteristics. Any higher order of linear system can thus be broken down into a combination of first and second order system. Interestingly enough, a lot of real life engineering circuits can be modelled as a second order system.

By definition, in order to achieve linear phase:

$$T_{ph} \text{ (phase delay)} = T_{gr} \text{ (Group delay)}.$$

In general: $T(j\omega) = |H(\omega)| \angle \theta(\omega)$

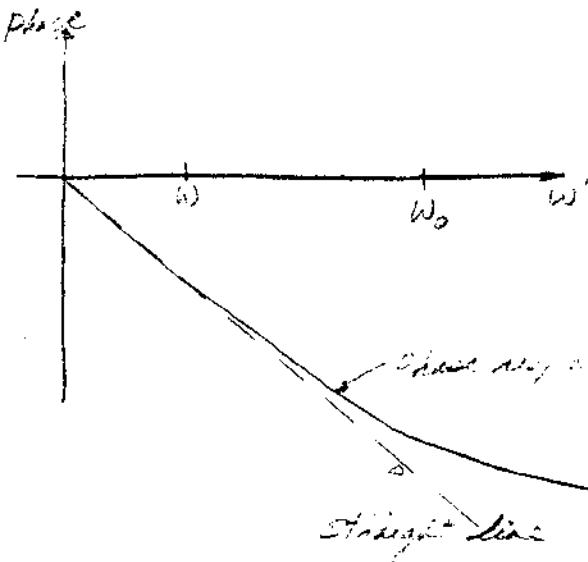

$$T_{ph} \triangleq -\frac{\theta(\omega)}{\omega} \quad ; \quad T_{gr} \triangleq -\frac{d\theta(\omega)}{d\omega}$$

For the case of real sinusoidal input
(See ref. #2 - Chapter 16)

$$\theta(\omega) = -\tan^{-1} \frac{2\omega\omega_0/\beta}{\omega_0^2 - \omega^2}$$

Let us assume that we want the phase response to be linear within a certain reasonable region where

$\omega \ll \omega_0$. (It is not possible to have a second order phase response to be linear over the whole frequency spectrum.)

Using the MacLaurin-series expansion of the inverse-tangent function:

$$\tan^{-1} x \approx x - \frac{x^3}{3} + \dots \quad (x^2 < 1)$$

$$\theta_{ph} = \frac{1}{\omega} \left(\tan^{-1} \frac{2\omega\omega_0/\beta}{\omega_0^2 - \omega^2} \right) \quad (\text{the argument can be shown to be } < 1; \omega \ll \omega_0)$$

$$= \frac{1}{\omega} \left\{ \frac{2\beta}{\omega_0^2 - \omega^2} - \frac{1}{3} \left(\frac{2\beta/\omega_0}{\omega_0^2 - \omega^2} \right)^3 \right\}$$

$$= \frac{1}{\omega} \left\{ \frac{2\beta/\omega_0}{1 - (\omega/\omega_0)^2} - \frac{1}{3} \left(\frac{2\beta/\omega_0}{1 - (\omega/\omega_0)^2} \right)^3 \right\}$$

$$T_{ph} = \frac{1}{\omega} \left[\left(2K \left(\frac{\omega}{\omega_0} \right) \left(1 + \left(\frac{\omega}{\omega_0} \right)^2 \right) \right] - \frac{1}{3} \left[2K \left(\frac{\omega}{\omega_0} \right) \left(1 + \left(\frac{\omega}{\omega_0} \right)^2 \right) \right]^3 \right]$$

Binomial series expansion for the denominator, $(1-x)^{-n} = 1 + nx + \dots$

$$T_{ph} = \frac{2|\beta|}{\omega_0} \left[1 + \left(\frac{\omega}{\omega_0} \right)^2 - \frac{4|\beta|^2}{3} \left(\frac{\omega}{\omega_0} \right)^2 \right]$$

$$T_{gr} = \frac{d}{d\omega} \tan^{-1} \frac{2\omega\omega_0|\beta|}{\omega_0^2 - \omega^2}$$

$$= \frac{2\omega\omega_0|\beta|}{1 + \left(\frac{2\omega\omega_0|\beta|}{\omega_0^2 - \omega^2} \right)^2} \frac{d}{d\omega} \left(\frac{2\omega\omega_0|\beta|}{\omega_0^2 - \omega^2} \right)$$

$$= \frac{2|\beta|}{\omega_0} \left[\frac{1 + \left(\frac{\omega}{\omega_0} \right)^2}{1 - \left(\frac{\omega}{\omega_0} \right)^2 (2 - 4|\beta|^2) + \left(\frac{\omega}{\omega_0} \right)^4} \right]$$

$$= \frac{2|\beta|}{\omega_0} \left[\frac{1 + \left(\frac{\omega}{\omega_0} \right)^2}{1 - [2\left(\frac{\omega}{\omega_0} \right)^2 - 4|\beta|^2\left(\frac{\omega}{\omega_0} \right)^2]} \right] \begin{matrix} \text{(Higher order term ignored)} \\ \frac{\omega}{\omega_0} \ll 1 \end{matrix}$$

$$= \frac{2|\beta|}{\omega_0} \left[1 + \left(\frac{\omega}{\omega_0} \right)^2 \right] \left[1 + (2 - 4|\beta|^2)\left(\frac{\omega}{\omega_0} \right)^2 \right]$$

$$(1-x)^{-n} = 1 + nx + \dots$$

$$= \frac{2|\beta|}{\omega_0} \left[1 + (3 - 4|\beta|^2)\left(\frac{\omega}{\omega_0} \right)^2 \right] \begin{matrix} \text{(For small values of } \omega \text{ and } \omega_0) \\ \text{ignoring higher order terms} \end{matrix}$$

$$\text{If } T_{ph} = T_{gr}; \text{ then } 1 - \frac{4}{3}|\beta|^2 = 3 - 4|\beta|^2$$

$$\boxed{|\beta| = 0.866; Q = \frac{1}{2|\beta|} = 0.577} \Rightarrow \begin{matrix} \text{Ideal condition} \\ \text{for linear phase} \end{matrix}$$

A-5 Experimental Determination of Damping Factor:

$$V_o(t) = V_i(t) * h(t)$$

(output) = (input) * (ZERO INPUT RESPONSE)

└ CONVOLUTION

$$\mathcal{L}[V_o(t)] = \mathcal{L}[V_i(t) * h(t)]$$

$$V_o(s) = \mathcal{L}[V_i(t)] \cdot \mathcal{L}[h(t)]$$

└ MULTIPLICATION

$$= V_i(s) H(s)$$

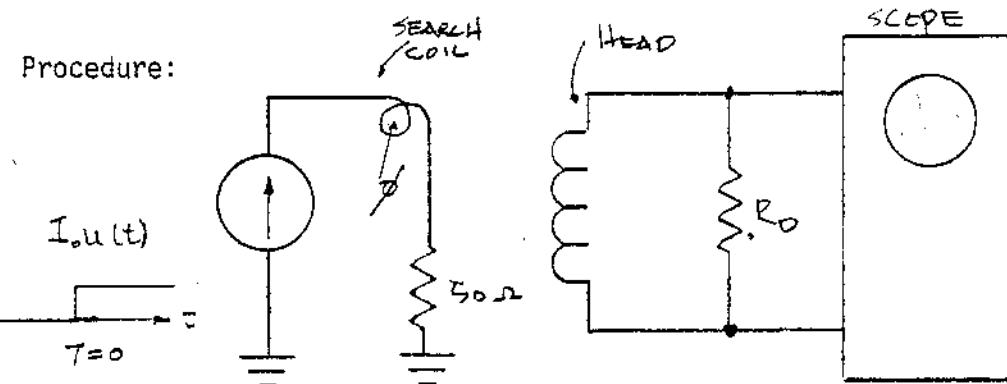

└ TRANSFER FUNCTION

$$\therefore \mathcal{L}[\delta(t)] = 1$$

$$\left\{ \begin{array}{l} V_o(t) = \delta(t) * h(t) \\ V_o(s) = H(s) \end{array} \right.$$

IMPULSE

The last two equations described that response of a system (network) to an impulse equalled to the system transfer function $H(s)$ in frequency domain and equalled to zero input response in time domain.

A step current is applied to the search coil. The flux generated equals to :

n_s = turns of search coil; I_o = Amplitude of current
 R_m = reluctance of the set up (consider to be constant)

$$= \frac{l}{\mu_0 A}$$

μ_0 = Permeability of air

A = Cross-section of head

l = Length of magnetic linkage surrounding search coil and head coil

Voltage induced at the head equals:

$$V_h = - n \frac{d\phi}{dt} \quad \gamma = \text{Number of turns of head coil}$$

$$= - n \frac{d(n_s I_o)}{dt} \quad \mu_0$$

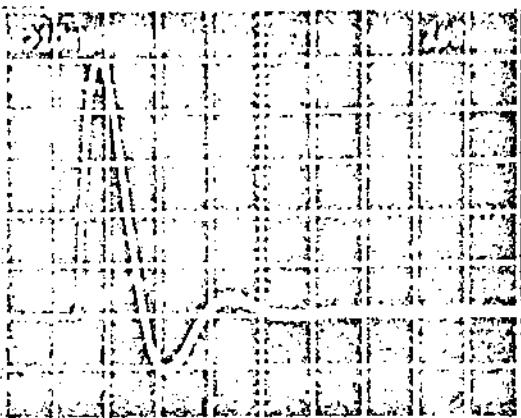

$$= - n n_s I_o S(t)$$

$$\frac{du(t)}{dt} \triangleq S(t)$$

This implied that by applying a step current to the search coil, we are really applying an impulse to the head. The response we see on a memory scope is the zero response of the head.

Result of experiment:

By finding the ratio between the main lobe and the second lobe from the scope, we can find ZETA of the system by using the following relationship:

$$\varsigma = \frac{\text{2nd lobe amplitude}}{\text{Main lobe amplitude}}$$

$$\varsigma = \frac{1.1}{5} = .22$$

$$|\varsigma| = \frac{\left| \frac{\ln \varsigma}{\pi} \right|}{\sqrt{1 + \left(\frac{\ln \varsigma}{\pi} \right)^2}}$$

$$|\varsigma| = \underline{0.434}$$

DAMPING RESISTOR $R = 6.8 \text{ k}\Omega$

* $L = 1.7 \text{ mH}$

$C = 5.9 \text{ pF}$

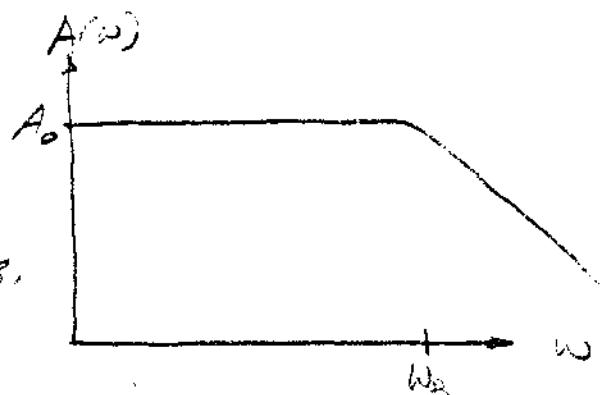

$R_D = 6.8 \text{ k} \parallel 44 \text{ k}\Omega = 5.89 \text{ k}\Omega$

This experimental result agreed very closely to the calculated value. $|\varsigma| = \underline{0.48}$

- * Inductance value could be in error due to improper range selected when measurement was taken. The value probably should have been 1.9 mH. In this case, the calculated damping factor agrees better with the experiment. $|\varsigma| = 0.46$

3 - 1. Derivation of real amplifier transfer function and related parameters.

For a typical linear amplifier with bandwidth of ω_B , its transfer function is

$$T(s) = \frac{A_0 \omega_B}{s + \omega_B} ; A_0 = A_1 \cdot A_2$$

≈ 100

typical linear amplifier response

With introduction of D.C. blocking capacitor, it becomes

$$\therefore A_0 = A_1 \cdot A_2$$

$$A_1 = \frac{2 \times 2.5 k\Omega}{R + \frac{1}{sC}}$$

(Standard gain of differential amplifier)

R = Total internal & external resistance

C = External D.C. blocking capacitors

$$A_2 \approx 10$$

$$\omega_B = 2\pi \times 5 \text{ MHz} \text{ (from spec.)}$$

$$\therefore A_0 = \frac{5000 s C}{5000 s C + 1} \times 10$$

$$T(s) = \frac{\frac{5000 s C \omega_B}{5000 s C + 1}}{s + \omega_B} \times 10$$

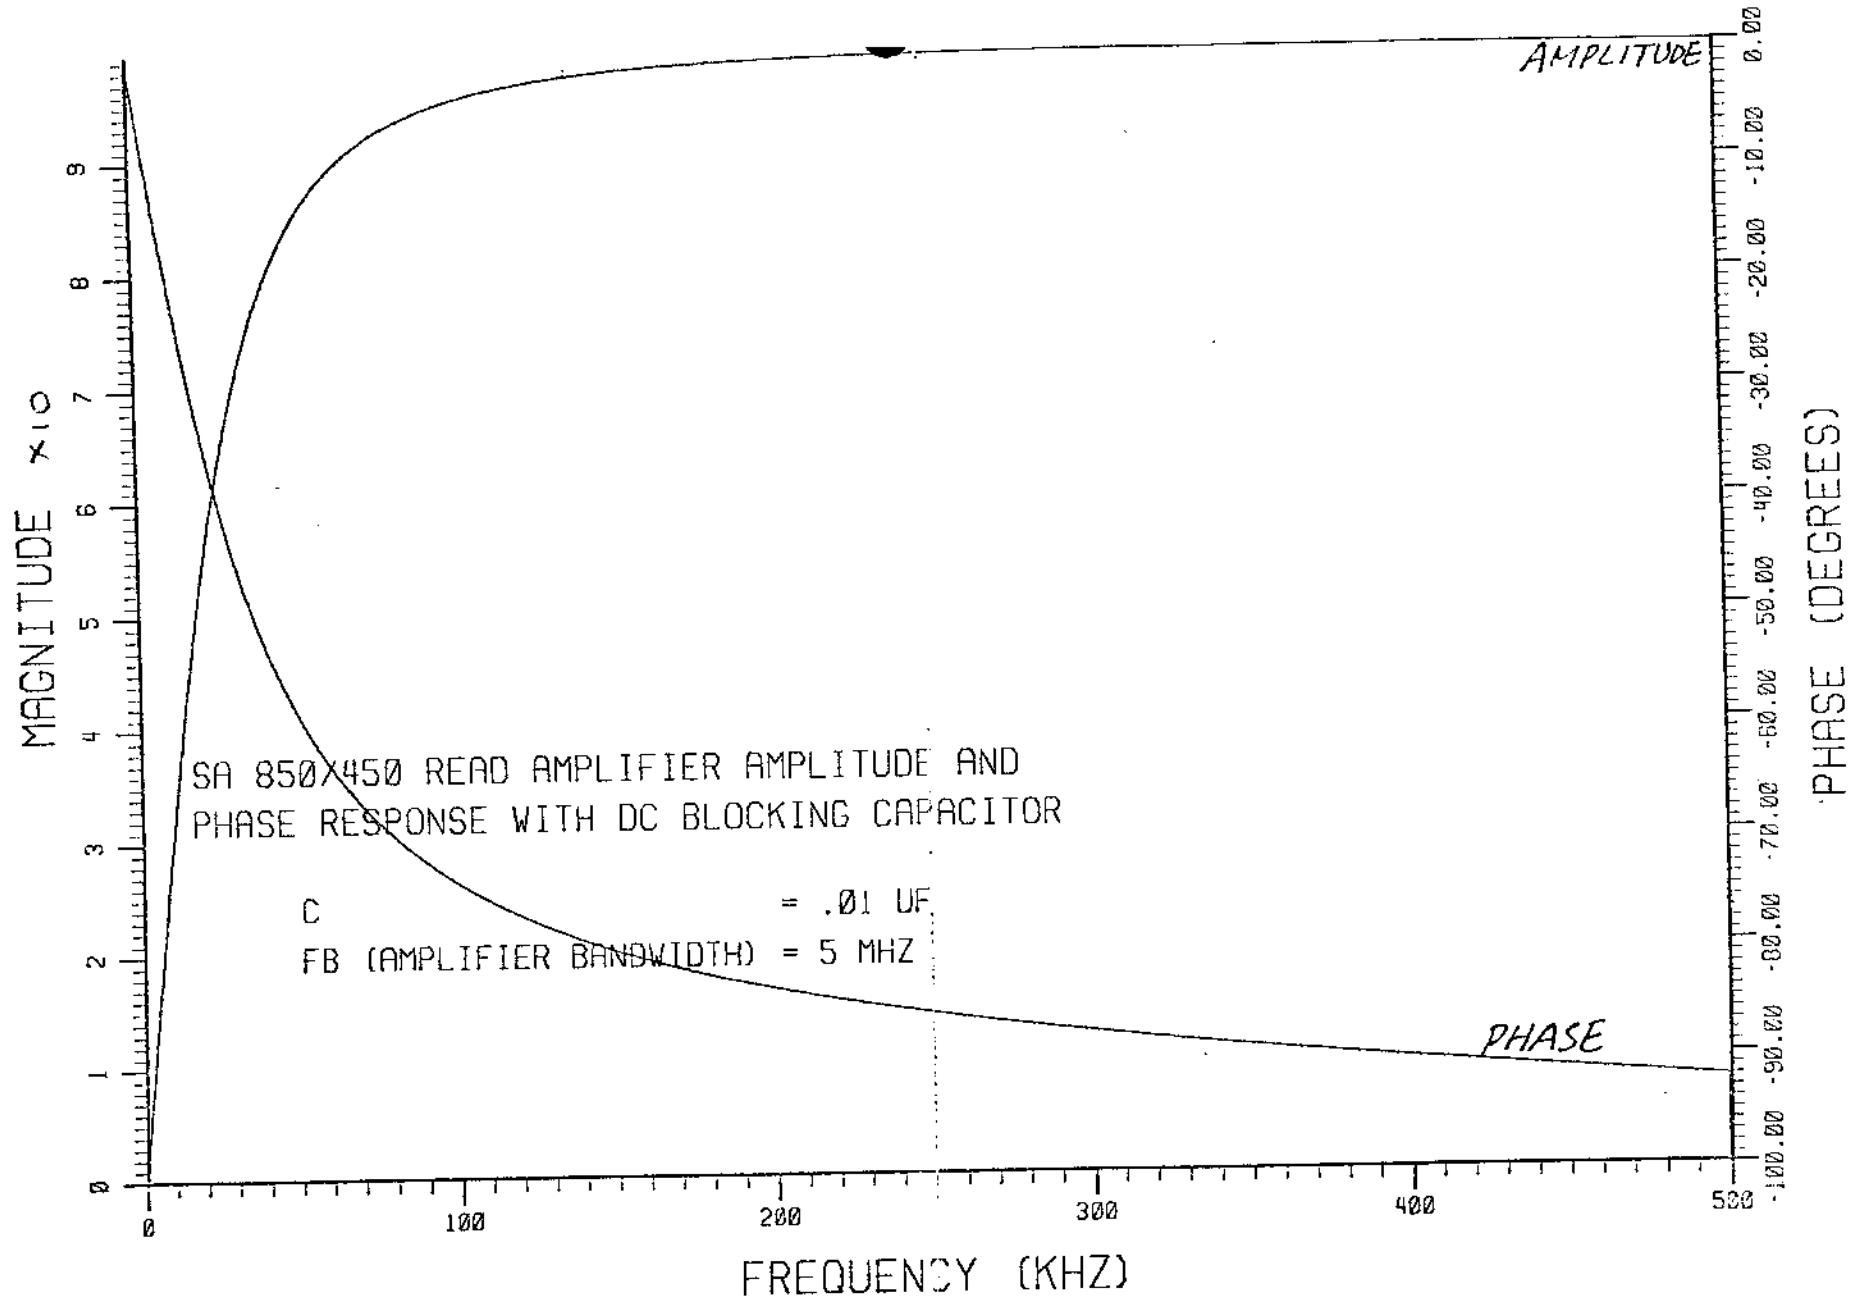

$$T(s) = \frac{\frac{100\omega_0}{s + \omega_0} (s + \frac{1}{500sC})}{(s + \omega_0)(s + \frac{1}{500C})} \times 10$$

$$T(j\omega) = \frac{100j\omega\omega_0}{(j\omega + \omega_0)(j\omega + \frac{1}{500C})}$$

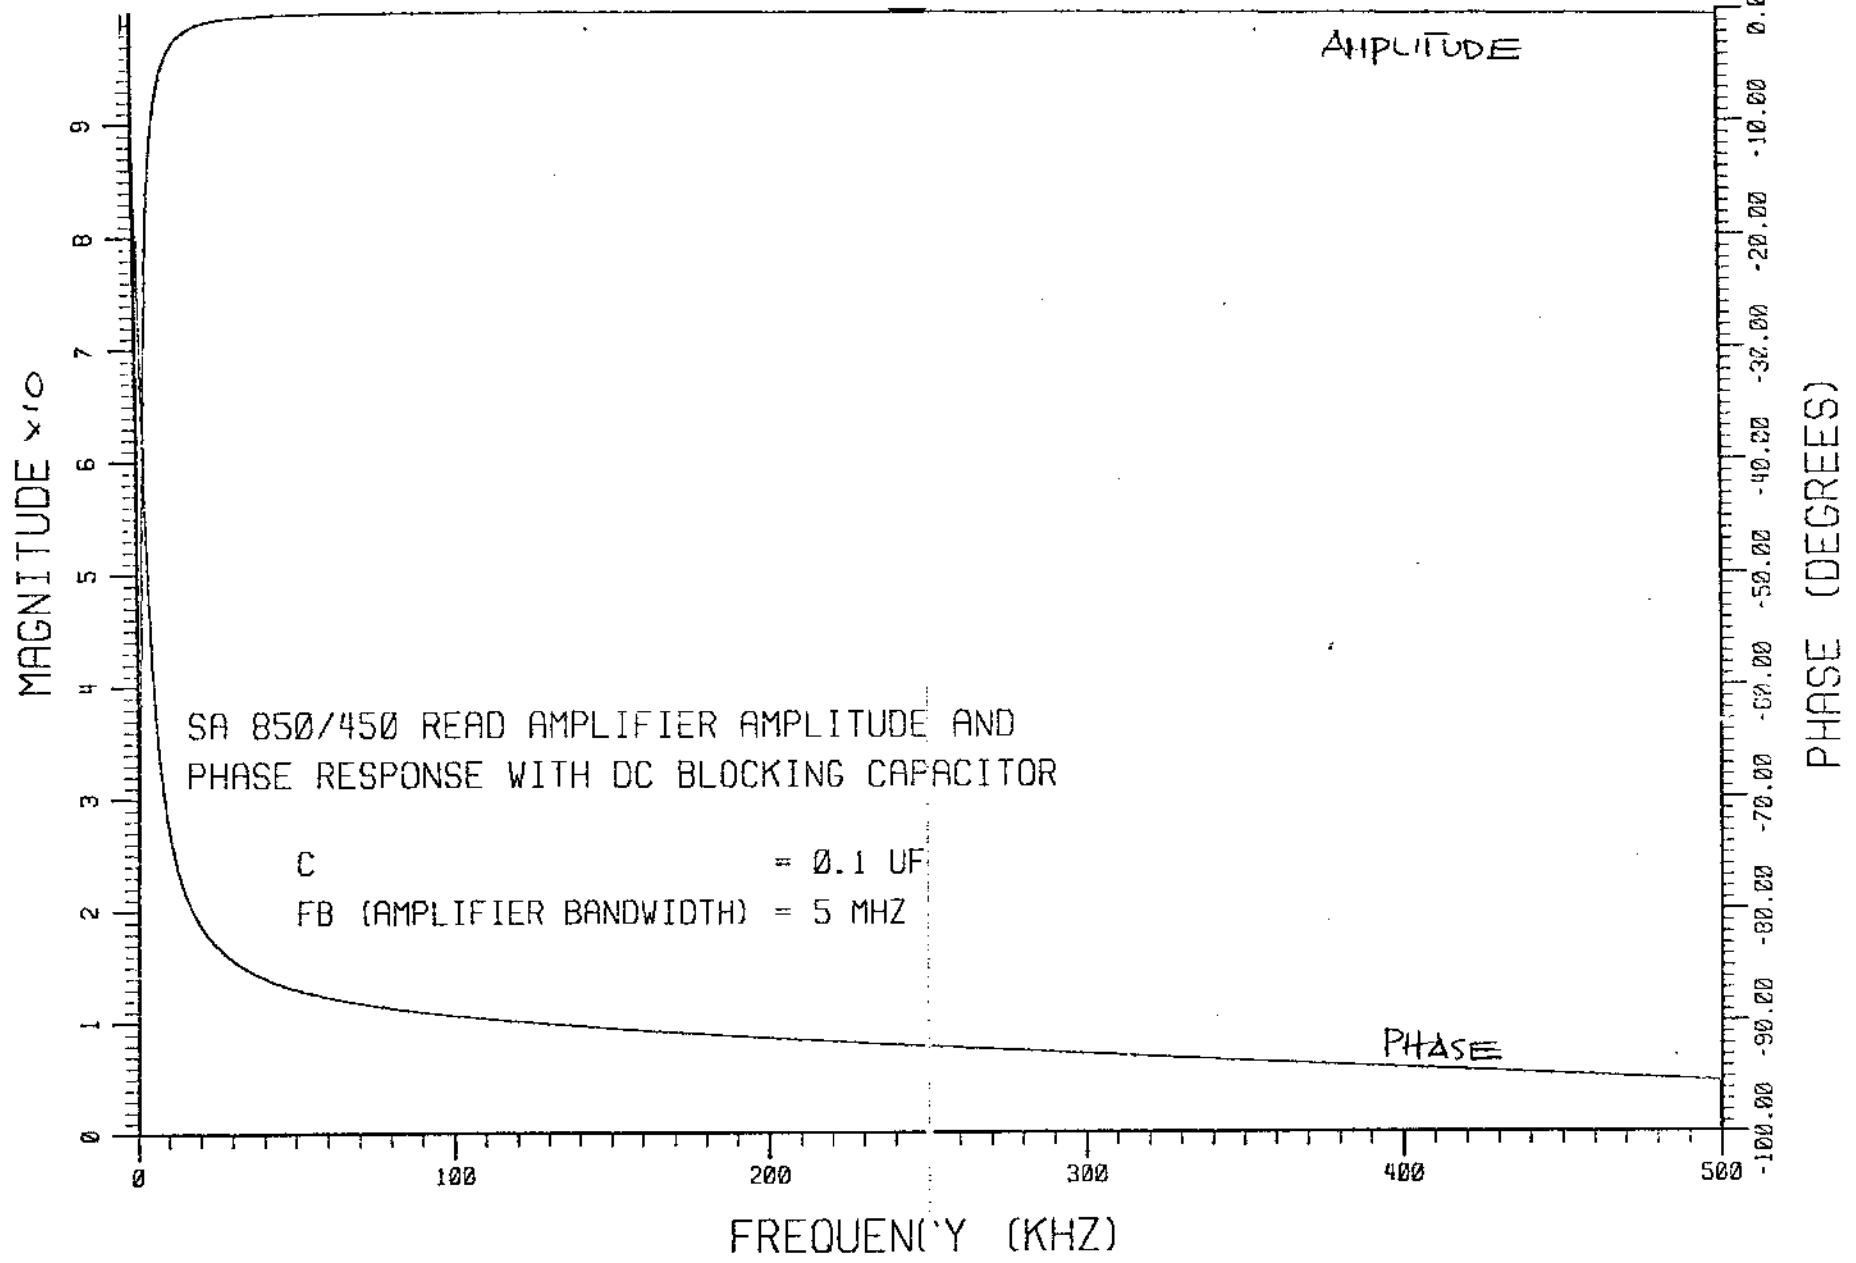

$$= \frac{100\omega\omega_0}{\sqrt{\omega^2 + \omega_0^2} \cdot \sqrt{\omega^2 + \left(\frac{1}{500C}\right)^2}} \angle 90^\circ - \tan^{-1} \frac{\omega}{\omega_0} - \tan^{-1} 500C\omega$$

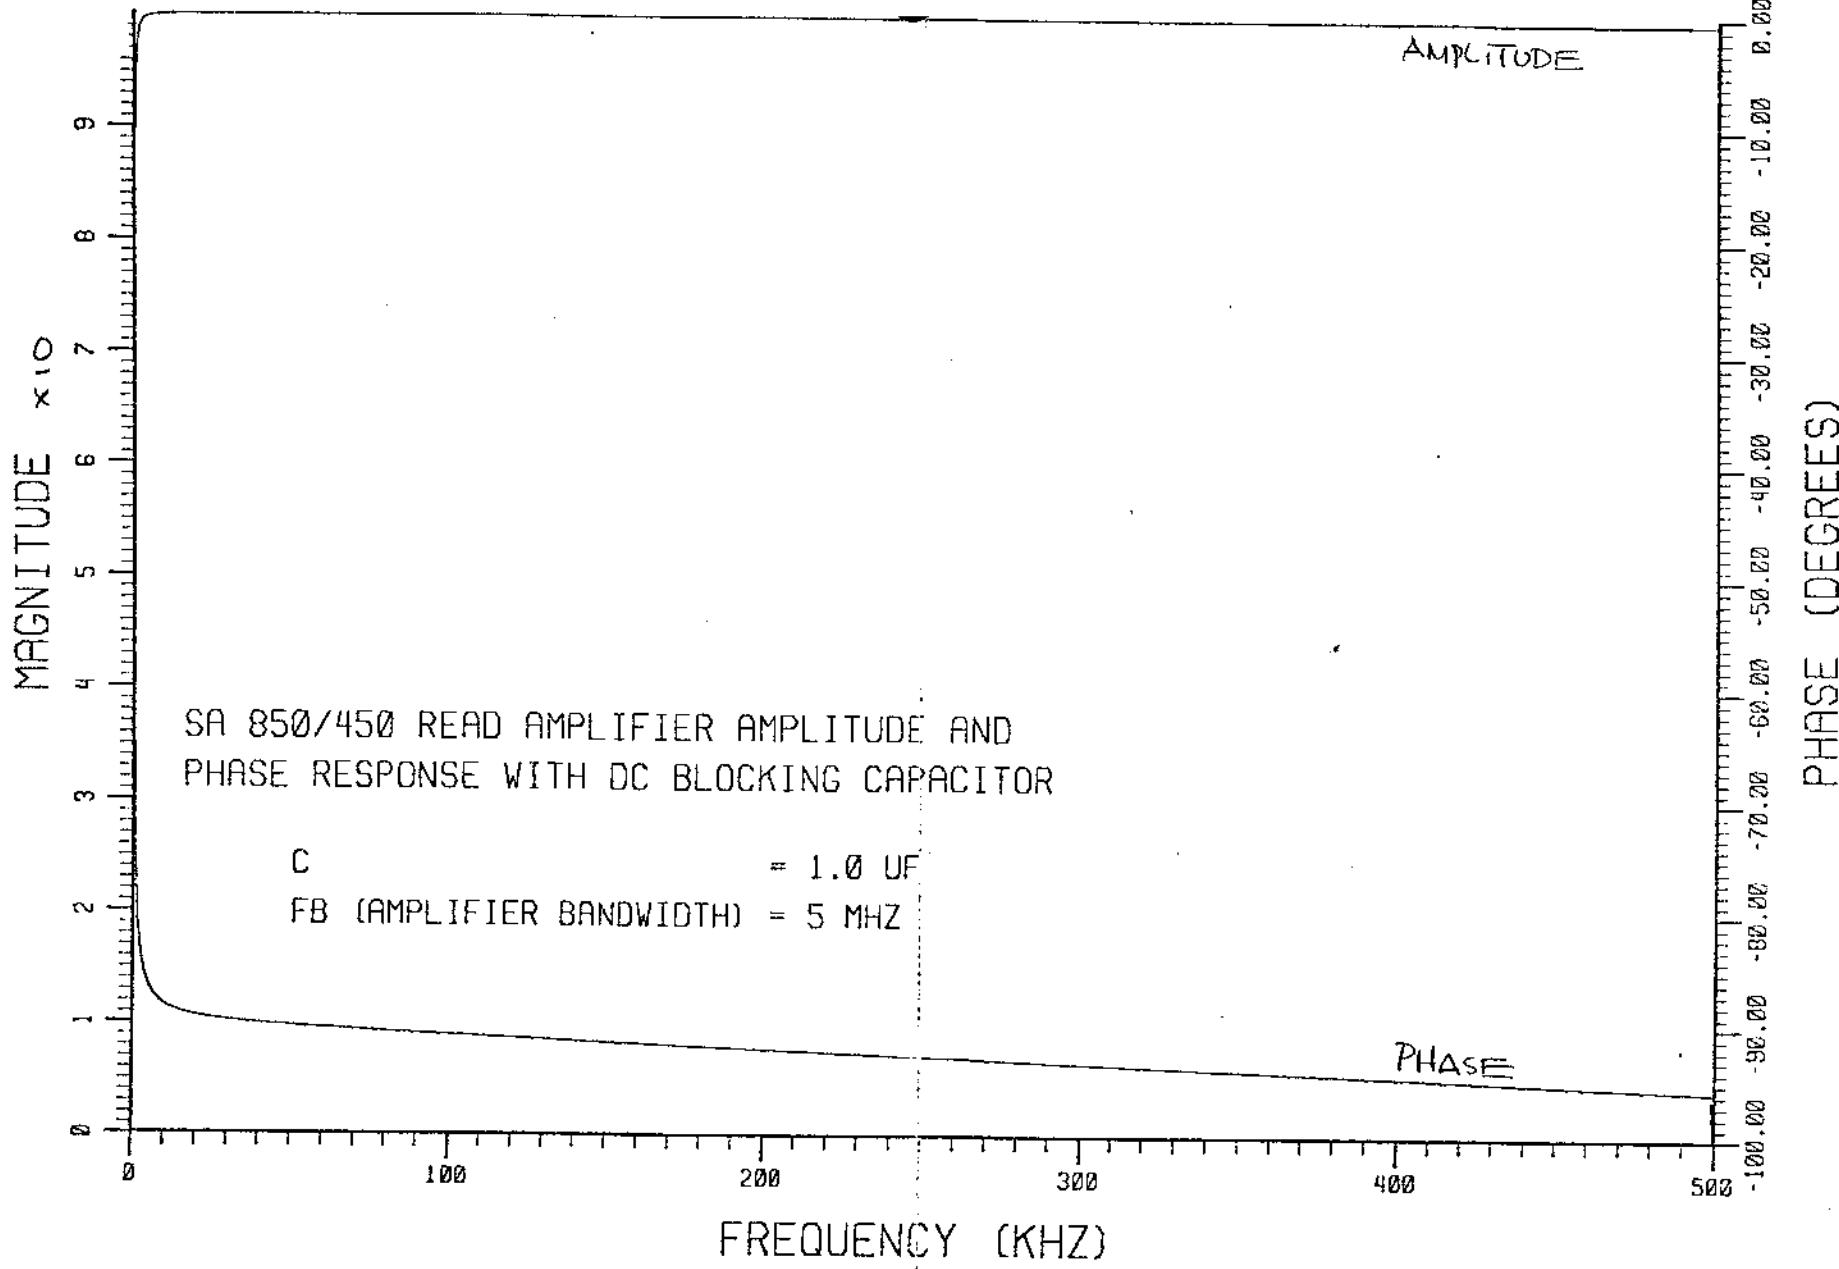

●

$$T(j2\pi f) = \frac{100 f f_0}{\sqrt{f^2 + f_0^2} \cdot \sqrt{f^2 + \left(\frac{1}{500 \times 2\pi C}\right)^2}} \angle 90^\circ - \tan^{-1} \frac{f}{f_0} - \tan^{-1} 2\pi \times 500Cf$$

C-1. Derivation of IBLH all pass filter transfer functions

Equivalent CKT:

$Z_3 \triangleq$ Input Impedance
of base filter

β = Forward current gain
of transistor

Superposition:

$$Z_x = \frac{(\beta Z_3 + R_2) \frac{1}{SC}}{R_2 + \beta Z_3 + \frac{1}{SC}} = \frac{(\beta Z_3 + R_2)}{SC(\beta Z_3 + R_2) + 1}$$

$$V_x = V_i \cdot \frac{Z_x}{R_1 + Z_x} = \frac{\frac{\beta Z_3 + R_2}{(SC(\beta Z_3 + R_2) + 1)}}{R_1 + \frac{\beta Z_3 + R_2}{(SC(\beta Z_3 + R_2) + 1)}}$$

$$= \left(\frac{\beta Z_3 + R_2}{SCR_1(\beta Z_3 + R_2) + \beta^2 Z_3 - R_1 + R_2} \right) V_i$$

$$V_o' \Big|_{V_x=0} = V_x \left(\frac{\beta Z_3}{R_2 + \beta Z_3} \right) = V_i \left(\frac{\beta Z_3 + R_2}{SCR_1(\beta Z_3 + R_2) + \beta^2 Z_3 - R_1 + R_2} \right) \left(\frac{\beta Z_3}{R_2 + \beta Z_3} \right)$$

$$= V_i \left(\frac{\beta Z_3}{SCR_1(\beta Z_3 + R_2) + \beta^2 Z_3 - R_1 + R_2} \right)$$

$$V_o' \Big|_{V_x \neq 0} = (-V_i) \left[\frac{\frac{(\beta Z_3 + R_2) R_1}{\beta Z_3 + R_1 + R_2}}{\frac{1}{SC} + \frac{(\beta Z_3 + R_2) R_1}{\beta Z_3 + R_1 + R_2}} \right] \left(\frac{\beta Z_3}{\beta Z_3 + R_2} \right)$$

$$= -V_i \left[\frac{SC(\beta Z_3 + R_2) R_1 / \beta Z_3}{\beta Z_3 + R_1 + R_2 + SCR_1(\beta Z_3 + R_2)(\beta Z_3 + R_2)} \right]$$

$$= -V_i \frac{SCR_1 / \beta Z_3}{SCR_1(\beta Z_3 + R_2) + \beta^2 Z_3 + R_1 + R_2}$$

$$V_o = V_i' + V_o''$$

$$= V_i \left(\frac{\beta Z_3 - SCR_1 \beta Z_3}{SCR_1 (\beta Z_3 + R_2) + \beta Z_3 + R_1 + R_2} \right)$$

$$= V_i \left(\frac{1 - SCR_1}{SCR_1 \left(1 + \frac{R_2}{\beta Z_3} \right) + \frac{R_1 + R_2}{\beta Z_3} + 1} \right)$$

For SA 650 : $\beta \geq 100$, $R_1 = R_2 = 1000 \Omega$

$Z_3 \approx 1.5k \parallel (1.5k + 1.5k)$ (In Passband of Bessel filter)

$$= 1k\Omega$$

$Z_3 \approx 1.5k \parallel 1.5k$

(In Stopband of Bessel filter)

$$= 750 \Omega$$

The above transfer function can be simplified to

$$T(s) = \frac{V_o}{V_i} = \left(\frac{1 - SCR_1}{1 + SCR_1} \right)$$

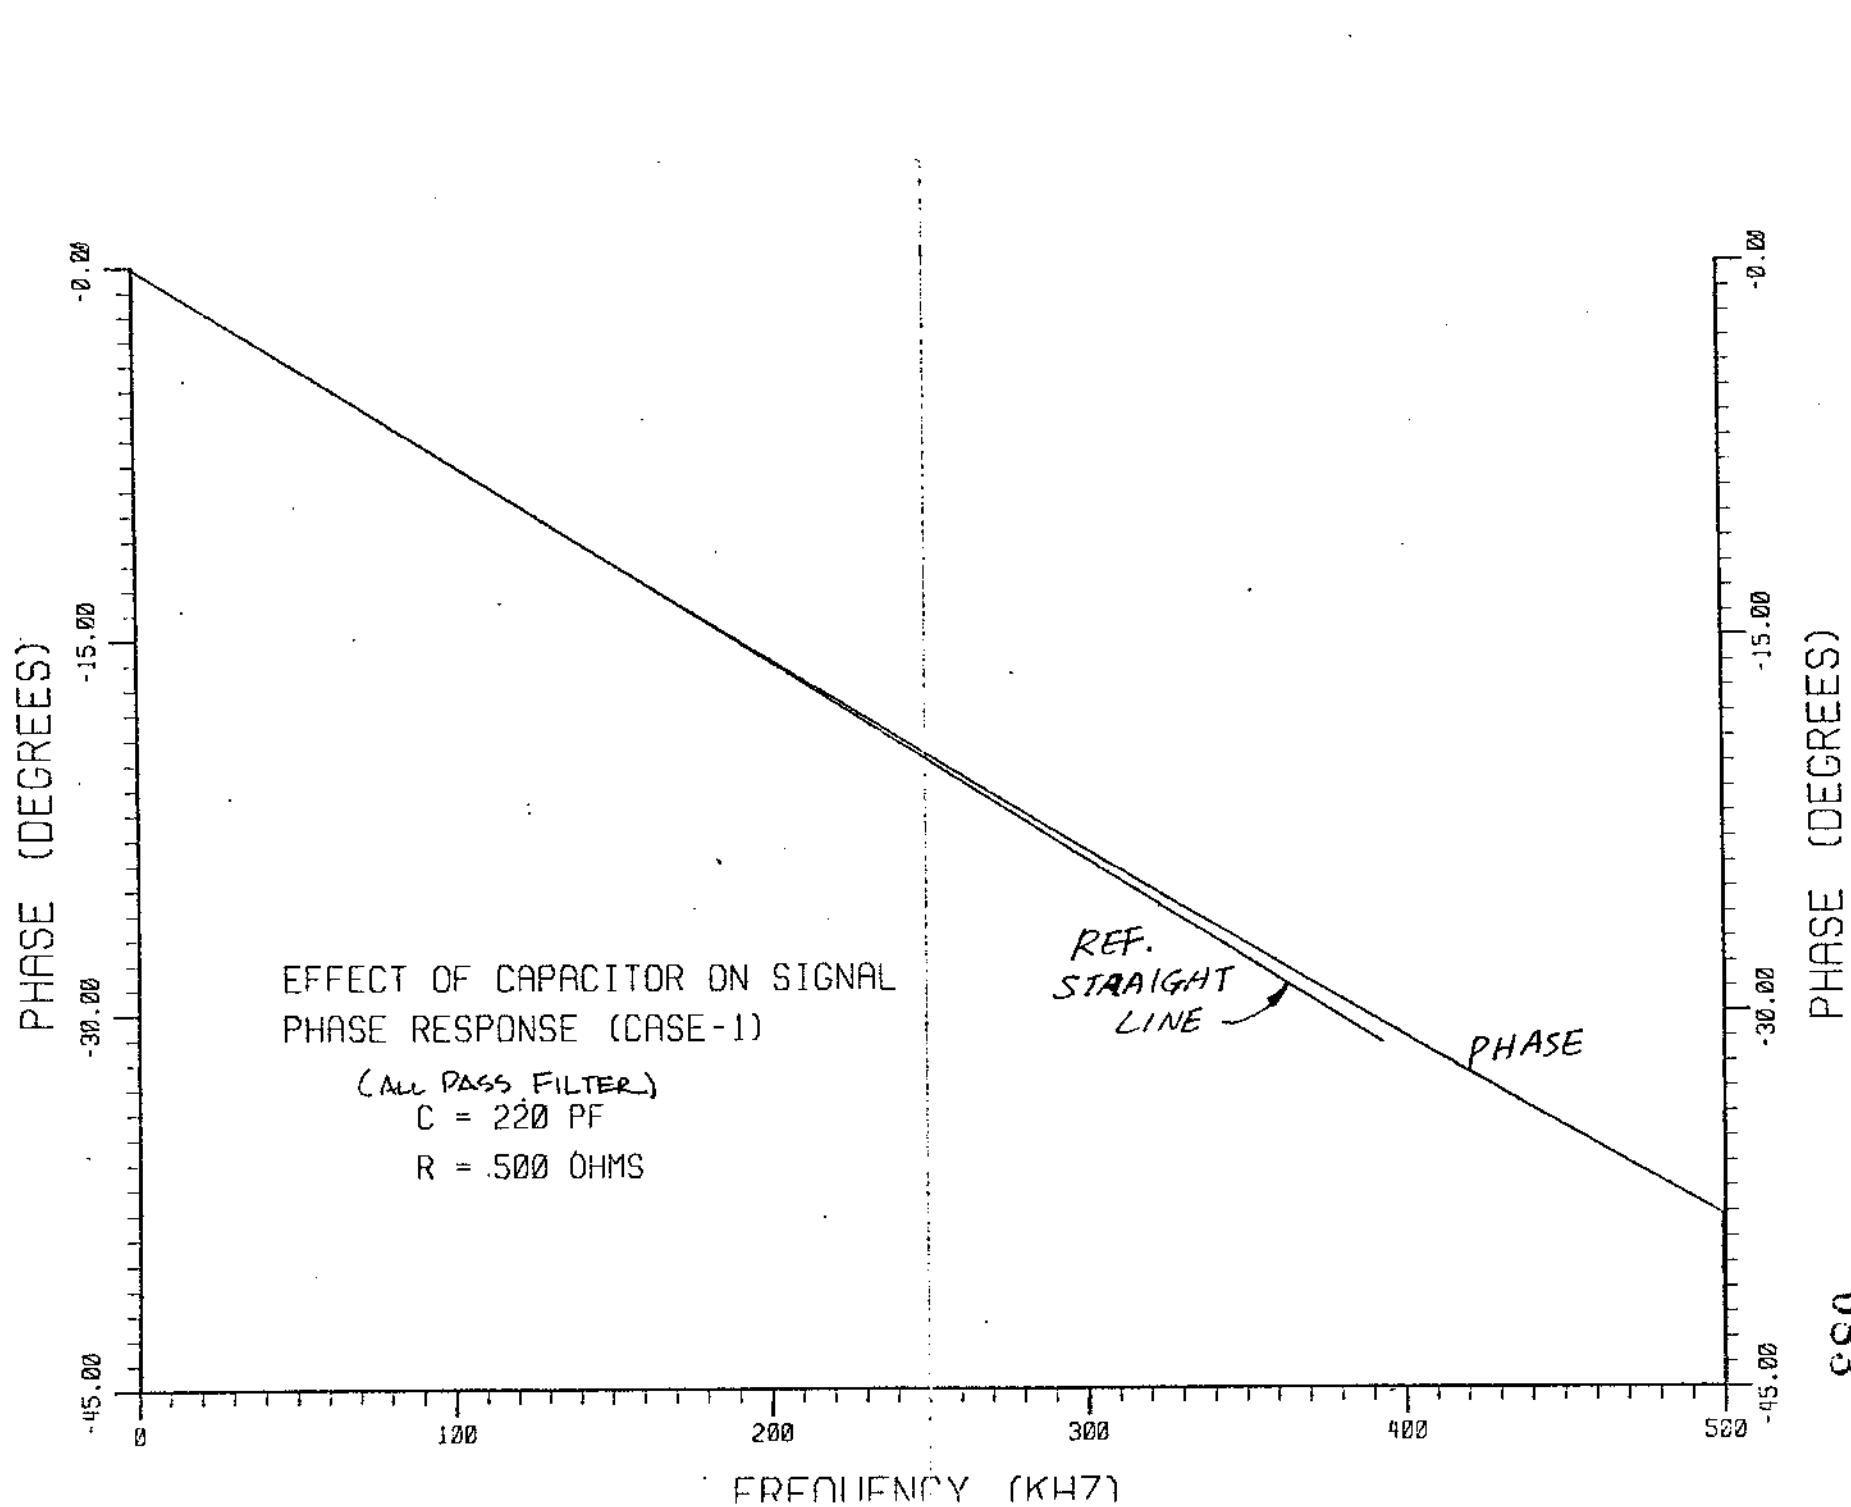

$$T(j\omega) = \frac{1 - j\omega CR_1}{1 + j\omega CR_1}$$

$$= \frac{\sqrt{1 + (j\omega CR_1)^2} \angle -\tan^{-1} \omega CR_1}{\sqrt{(1 + \omega CR_1)^2} \angle \tan^{-1} \omega CR_1}$$

$$= -2 \tan^{-1} \omega CR_1$$

$$\boxed{T(j2\pi f) = -2 \tan^{-1} 2\pi f CR_1}$$

This is obvious an all-pass function with magnitude of 1.

E-1 Derivation of differentiator transfer function with/without parallel resistor:

The current source according to calculation is $1.8mA$.
 For conservative reason, $1mA$ is being used for the following analysis. For A.C. analysis purpose, resistors R_x & $10k\Omega$ are ignored. They are there to adjust D.C. offset (asymmetry).

Case I - R_x does not exist :

$$\frac{V_o}{V_n} = \frac{R_c}{2R_e + Z}$$

$$Z = R_o + sL_o + \frac{1}{sC_o}$$

$$= \frac{sL_o R_o + s^2 L_o C_o + 1}{s C_o}$$

$$\begin{aligned}\frac{V_o}{V_{in}} &= \frac{R_C}{2R_e + \frac{SC_0 R_e + s^2 L_0 C_0 + 1}{SC_0}} \\ &= \frac{R_C}{\frac{2SC_0 R_e + SC_0^2 R_e + s^2 L_0 C_0 + 1}{SC_0}} \\ &= \frac{SC_0 R_C}{s^2 L_0 C_0 + S(2C_0 R_e + s^2 L_0 C_0) + 1}\end{aligned}$$

$$T(s) = \frac{R_C}{L_0} \cdot \frac{s}{s^2 + s(\frac{2R_e + R_C}{L_0}) + \frac{1}{L_0 C_0}}$$

$$|f| = \left(\frac{2R_e + R_C}{2} \right) \sqrt{\frac{C_0}{L_0}}$$

$$\omega_0 = \sqrt{\frac{1}{L_0 C_0}}$$

Case II. - $R_x \parallel C_0$:

$$R_x \parallel C_0 = \frac{R_x \cdot \frac{1}{SC_0}}{R_x + \frac{1}{SC_0}}$$

$$= \frac{R_x}{SC_0 R_x + 1}$$

$$\begin{aligned}Z &= R_0 + SC_0 + \frac{R_1}{SC_0 R_1 + 1} \\ &= \frac{SC_0 R_0 R_x + S^2 L_0 C_0 R_1 + SC_0 + S^2 R_1}{SC_0 R_x + 1}\end{aligned}$$

$$Z = \frac{S^2 L_0 C_0 R_x + S(L_0 + C_0 R_x R_s) + R_s + R_x}{S C_0 R_x + 1}$$

$$\begin{aligned}
 T(s) &= \frac{V_o}{V_i} = \frac{R_o}{2R_e + \frac{S^2 L_0 C_0 R_x + S(L_0 + C_0 R_x R_s) + R_s + R_x}{S C_0 R_x + 1}} \\
 &= \frac{S C_0 R_x R_o + R_o}{S^2 L_0 C_0 R_x + S(L_0 + C_0 R_x R_s - 2R_e C_0 R_x) + R_s + R_x} \\
 &= \frac{R_o (S + \frac{1}{C_0 R_x})}{L_0 (S^2 + S(\frac{L_0 + C_0 R_x R_s - 2R_e C_0 R_x}{2L_0 C_0 R_x}) + \frac{R_s + R_o + 2R_e}{L_0 C_0 R_x})} \\
 \boxed{T(s) = \frac{R_o}{L_0} \cdot \frac{(S + \frac{1}{C_0 R_x})}{(S^2 + S(\frac{1}{C_0 R_x} + \frac{R_s + 2R_e}{L_0}) + \frac{1}{L_0 C_0})}} \quad (R_x \gg R_s + R_o)
 \end{aligned}$$

$$|B| = \frac{\sqrt{L_0 C_0}}{2} \left(\frac{1}{C_0 R_x} + \frac{R_s + 2R_e}{L_0} \right)$$

$$\omega_n = \frac{1}{\sqrt{L_0 C_0}}$$

We can see how a zero is being moved from infinity to $-\frac{1}{C_0 R_x}$ by comparing both cases. The self-resonant frequency is not effected and the damping factor is only effected by a negligible amount.

To carry case II further, since this is the circuit that is being used on our SAT50/450 drivers,

$$\begin{aligned}
 T(s) &= \frac{R_c}{L_D} \frac{s + \frac{1}{C_o R_x}}{(s^2 + 2\zeta s + \omega_0^2)} \\
 &= \frac{R_c}{L_D} \frac{s + \frac{1}{C_o R_x}}{(s + \zeta + \sqrt{\zeta^2 - \omega_0^2})(s + \zeta - \sqrt{\zeta^2 - \omega_0^2})} \\
 T(j\omega) &= \frac{R_c}{L_D} \frac{\sqrt{\omega^2 + (\frac{1}{C_o R_x})^2} \angle \tan^{-1} C_o R_x \omega}{(j\omega + \zeta + j\sqrt{\omega^2 - \zeta^2})(j\omega + \zeta - j\sqrt{\omega^2 - \zeta^2})} \\
 &= \frac{R_c}{L_D} \cdot \frac{\sqrt{\omega^2 + (\frac{1}{C_o R_x})^2}}{\sqrt{[(\omega + \sqrt{\omega^2 - \zeta^2})^2 + \zeta^2][(\omega - \sqrt{\omega^2 - \zeta^2})^2 + \zeta^2]}} \angle \Theta(\omega) \\
 A(\omega) &= \frac{R_c}{L_D} \frac{\sqrt{\omega^2 + (\frac{1}{C_o R_x})^2}}{\sqrt{[(\omega^2 + \omega_0^2) + 2\omega \sqrt{\omega_0^2 - \zeta^2}] [(\omega^2 + \omega_0^2) - 2\omega \sqrt{\omega^2 - \zeta^2}]}} \\
 &= \frac{R_c}{L_D} \frac{\sqrt{\omega^2 + (\frac{1}{C_o R_x})^2}}{\sqrt{[(\omega^2 + \omega_0^2)^2 - (2\omega \sqrt{\omega_0^2 - \zeta^2})^2]}
 \end{aligned}$$

$$A(2\pi f) = \frac{R_c}{L_D} \frac{\sqrt{(2\pi f)^2 + (\frac{1}{C_o R_x})^2}}{\sqrt{[(2\pi f^2 + 2\omega_0^2)^2 - (4\pi f \sqrt{(2\pi f)^2 + \zeta^2})^2]}} \quad |\zeta| \leq 1$$

$$\Theta(\omega) = \angle \tan^{-1} C_o R_x \omega - \tan^{-1} \frac{\omega + \sqrt{\omega^2 - \zeta^2}}{\zeta} - \tan^{-1} \frac{\omega - \sqrt{\omega^2 - \zeta^2}}{\zeta}$$

$$\Theta(2\pi f) = \angle \tan^{-1} C_o R_x 2\pi f - \tan^{-1} \frac{\zeta + \sqrt{1 - \zeta^2}}{|\zeta|} - \tan^{-1} \frac{\zeta - \sqrt{1 - \zeta^2}}{|\zeta|}$$

E6 E7

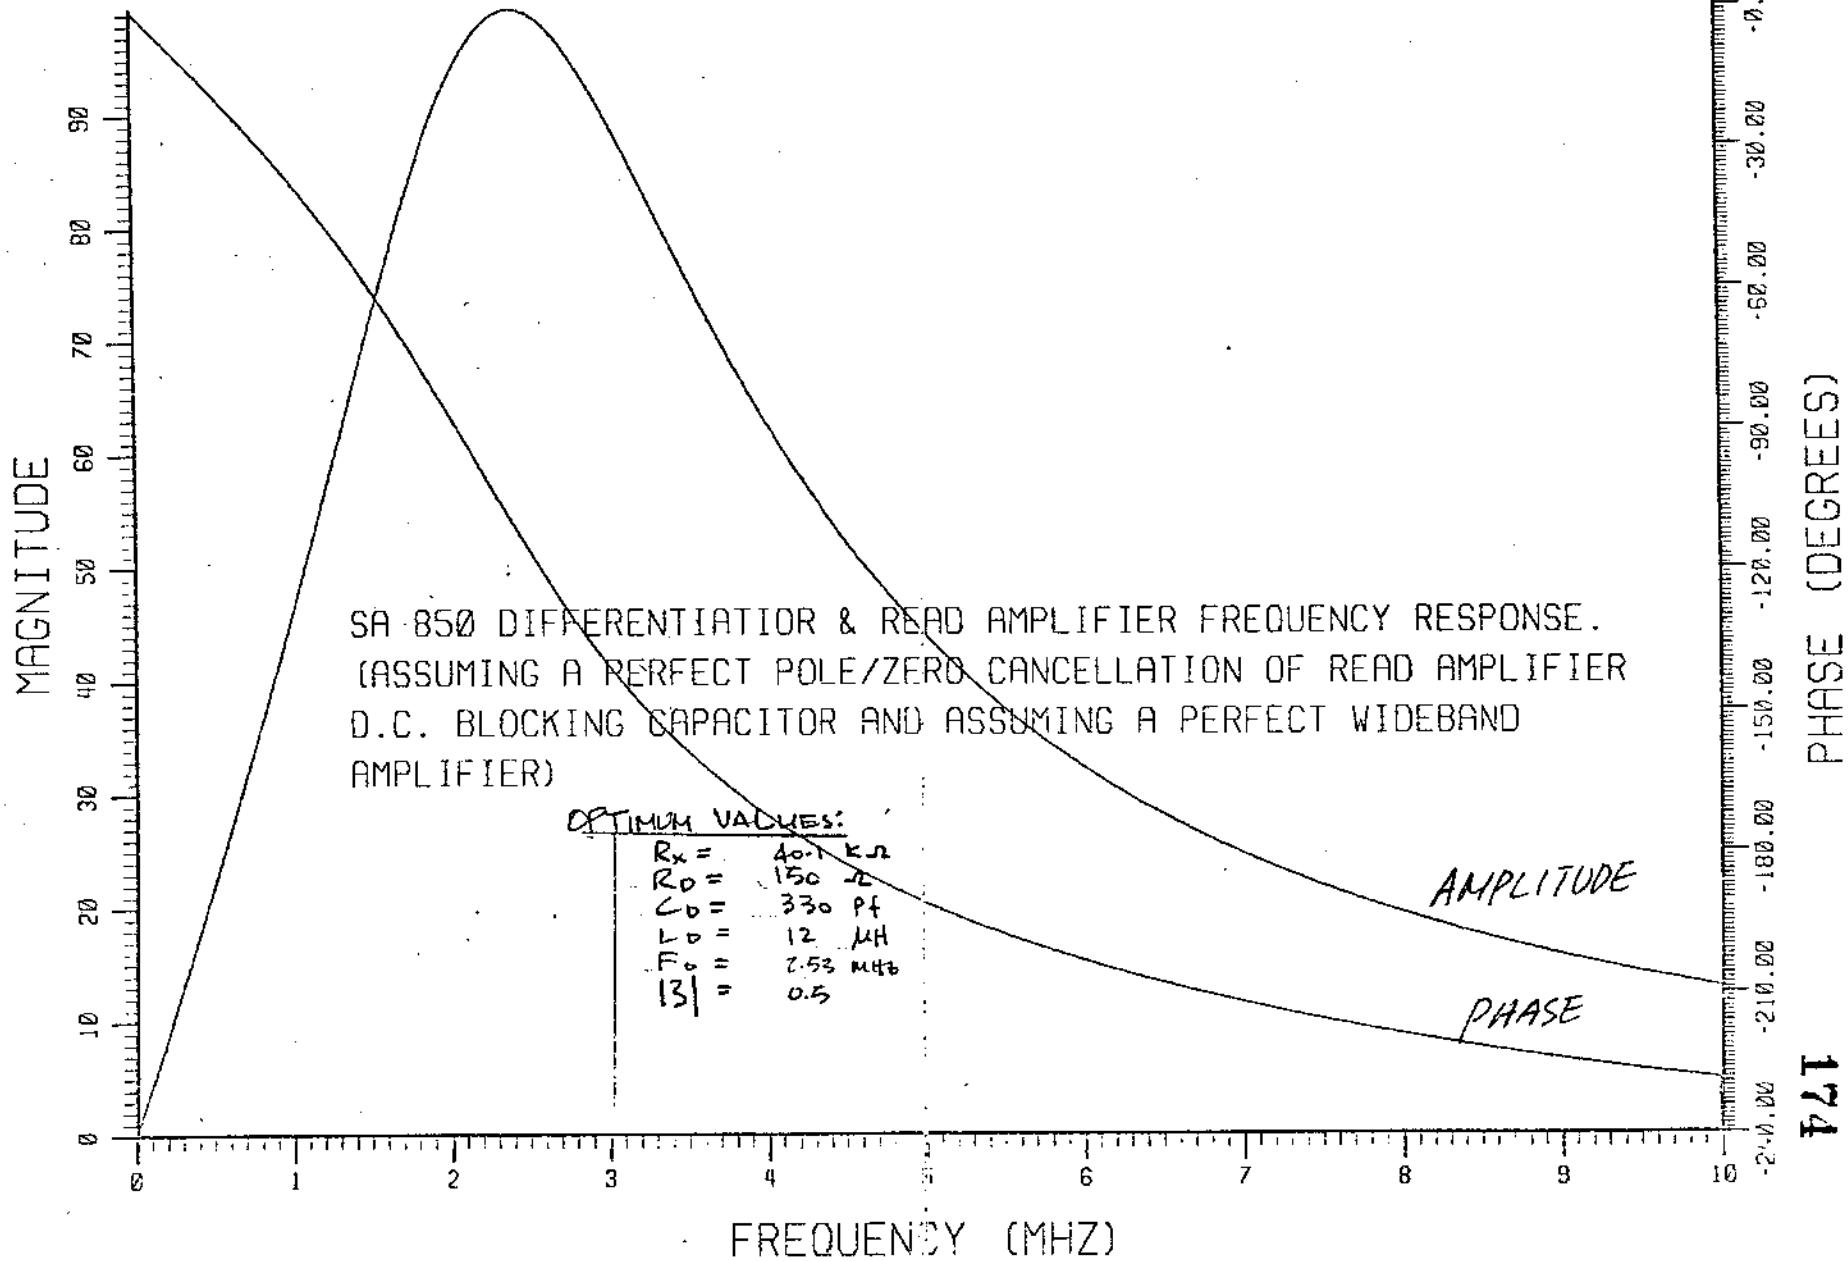

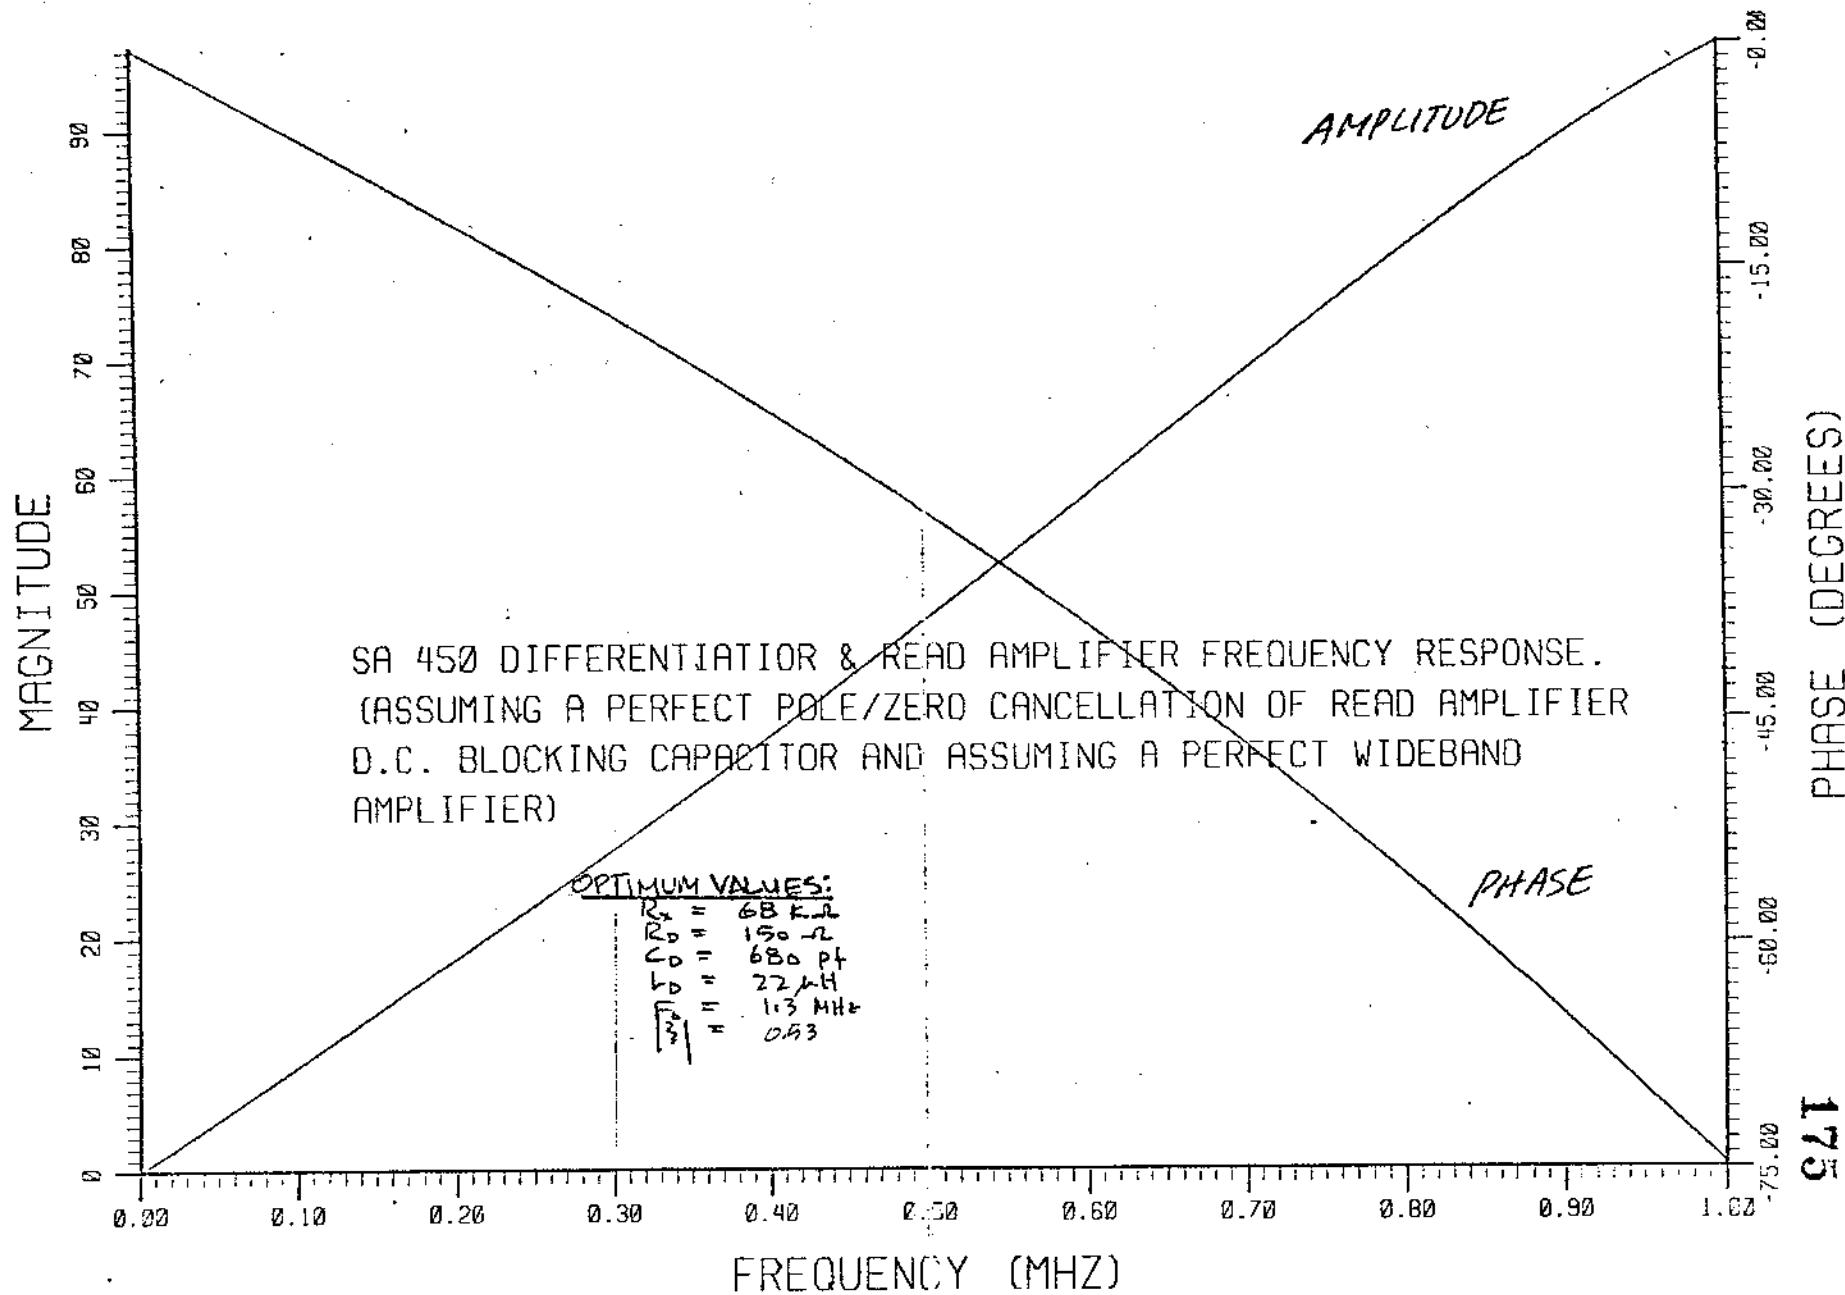

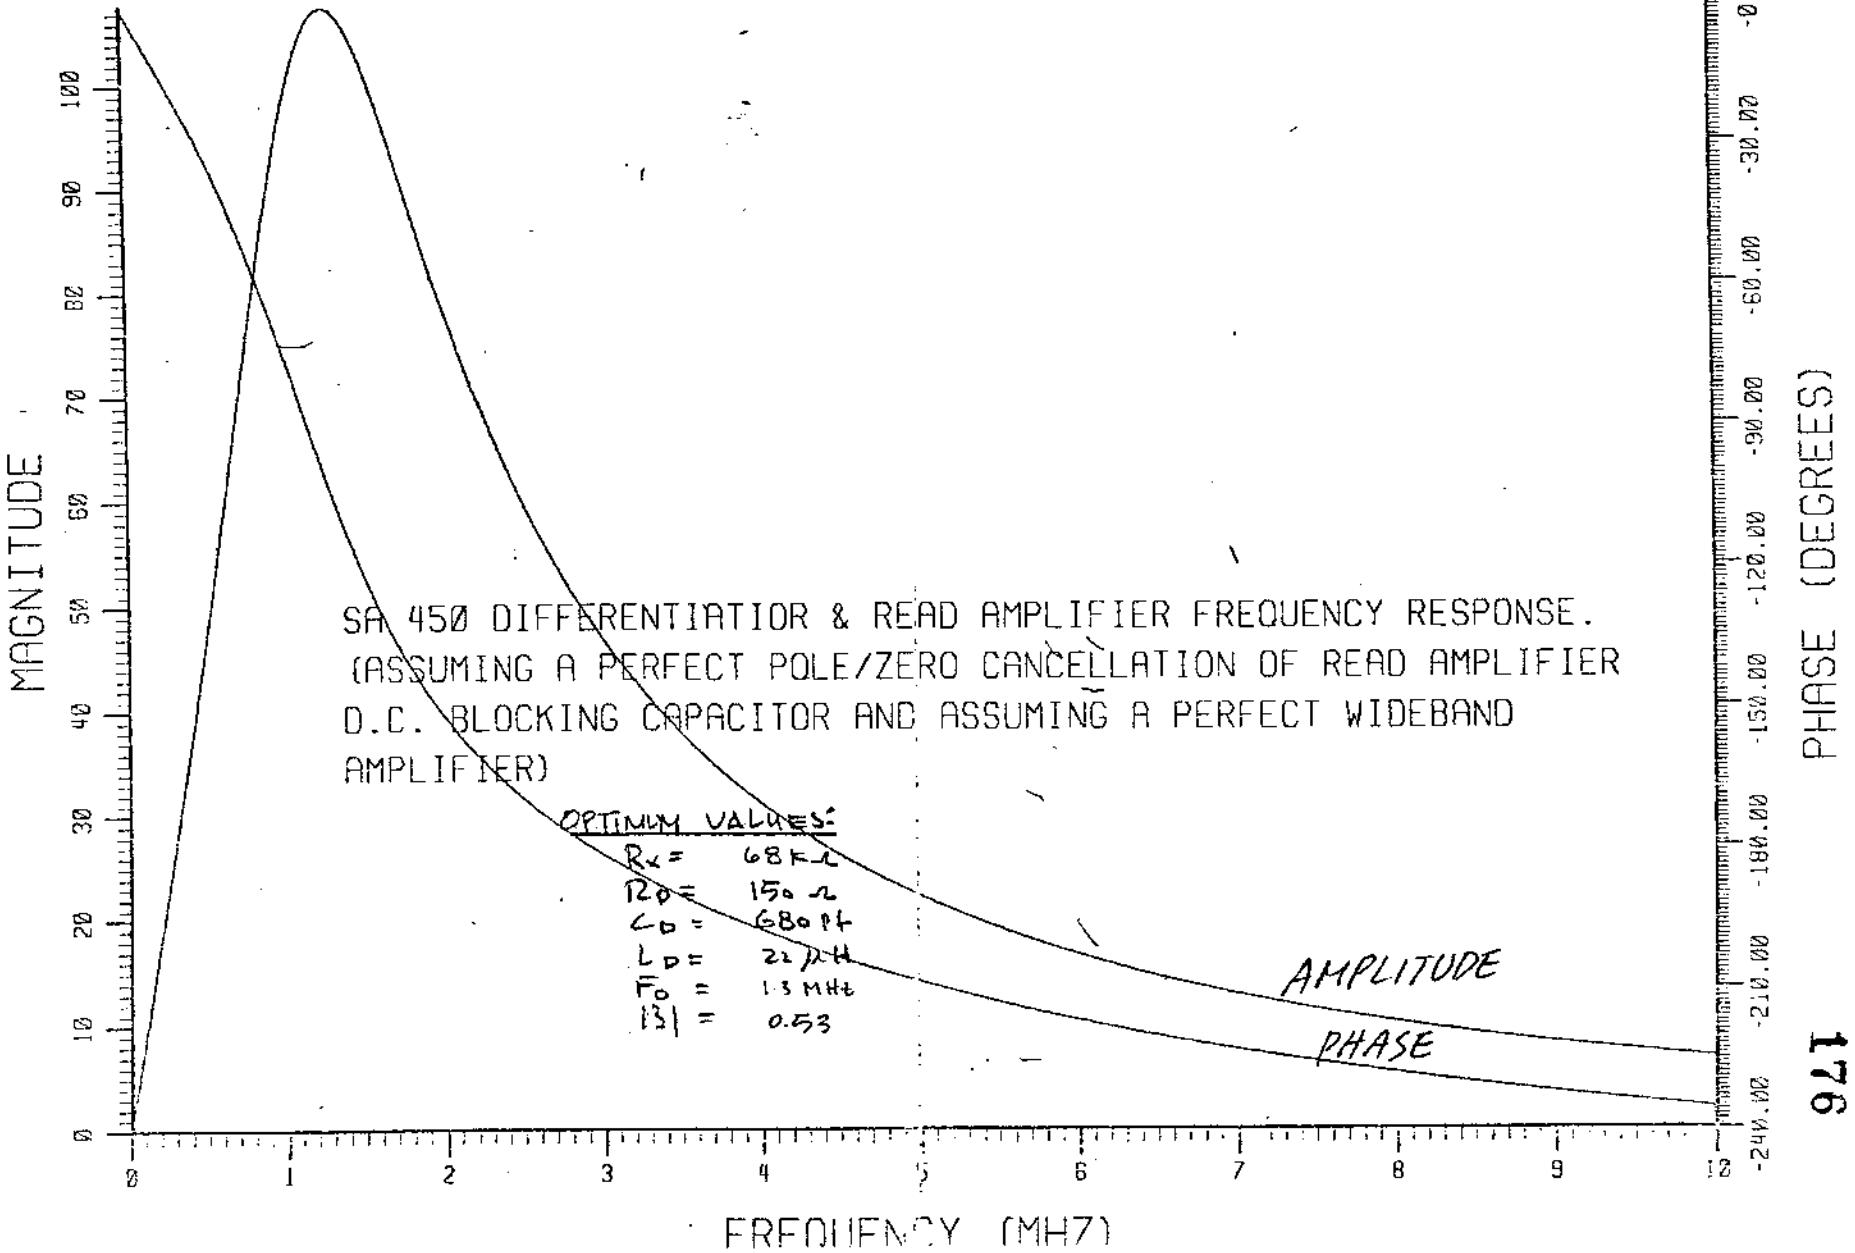

E-8. Derivation of time response of differentiator for pure sinewave input.

Sinewave was chosen for its relatively simple Laplace transform form. Also, it is quite close to the lead output signal for time delay evaluation purposes. The transfer function for Case I in Appendix E-1 shows that:

$$T(s) = \frac{R_c}{L_0} \cdot \frac{s + \frac{1}{C_0 R_x}}{(s + \zeta)^2 - \zeta^2 + \omega_0^2}$$

IF $V_{in} = \sin \omega t \cdot u(t)$

$$V_i(s) = \mathcal{L}(V_{in}) = \frac{\omega}{s^2 + \omega^2}$$

$$V_o(t) = V_i(t) * h(t) \quad \begin{matrix} \text{Convolution} \\ \text{Zero input response} \end{matrix}$$

$$V_o(s) = V_i(s) \cdot H(s) \quad \text{Transfer function}$$

$$\begin{aligned} V_o(s) &= \left(\frac{\omega}{s^2 + \omega^2} \right) \cdot \left(\frac{R_c}{L_0} \cdot \frac{s + \frac{1}{C_0 R_x}}{(s + \zeta)^2 - \zeta^2 + \omega_0^2} \right) \\ &= \frac{AS + B}{s^2 + \omega^2} + \frac{CS + D}{(s + \zeta)^2 - (\zeta^2 - \omega_0^2)} \quad \begin{matrix} \text{Partial fraction} \\ \text{expansion} \end{matrix} \end{aligned}$$

$$(AS + B)(s^2 + 2\zeta s + \omega_0^2) + (Cs + D)(s^2 + \omega^2) = \frac{R_c}{L_0} \omega s + \frac{R_c \omega}{L_0 C_0 R_x}$$

$$AS^3 + (B + 2\zeta A)s^2 + (2\zeta B + Aw^2)s + B\omega_0^2 + (s^2 + \omega^2)Cs + (s^2 + \omega^2)Ds =$$

$$\frac{R_c}{L_0} \omega s + \frac{R_c \omega}{L_0 C_0 R_x}$$

Equating equal power terms:

$$\begin{cases} A + C = 0 \\ 2\zeta A + B + D = 0 \\ \omega_0^2 A + 2\zeta B + \omega^2 C = \frac{R_c w}{L_0} \\ \omega_0^2 B + \omega^2 D = \frac{R_c w}{L_0 C_0 R_x} \end{cases}$$

To solve for $A, B, C \& D$, a determinant approach is deemed necessary

$$\Delta = \begin{vmatrix} 1 & 0 & 1 \\ 2\zeta & \omega^2 & 0 \\ \omega_0^2 & 0 & \omega^2 \end{vmatrix} + \begin{vmatrix} 2\zeta & 1 & 1 \\ \omega_0^2 & 2\zeta & 0 \\ 0 & \omega_0^2 & \omega^2 \end{vmatrix}$$

$$= \omega^4 - \omega_0^2 \omega^2 + 4\zeta^2 \omega^2 + \omega_0^4 - \omega_0^2 \omega^2$$

$$\Delta = \omega^4 + \omega_0^4 - 2\omega_0^2 \omega^2 + 4\zeta^2 \omega^2 = (\omega^2 - \omega_0^2)^2 + (2\zeta \omega)^2$$

$$A = \frac{\begin{vmatrix} 0 & 1 & 1 \\ \frac{R_c w}{L_0} & 2\zeta & 0 \\ \frac{R_c w}{L_0 C_0 R_x} & \omega_0^2 & \omega^2 \end{vmatrix}}{\Delta} = \frac{\frac{R_c w \omega_0^2}{L_0} - \frac{2\zeta R_c w}{L_0 C_0 R_x} - \frac{R_c w^3}{L_0}}{\Delta}$$

$$B = \frac{\begin{vmatrix} 2\zeta & 0 & 1 \\ \omega_0^2 & \frac{R_c w}{L_0} & 0 \\ 0 & \frac{R_c w}{L_0 C_0 R_x} & \omega^2 \end{vmatrix} + \begin{vmatrix} 0 & 0 & 1 \\ \frac{R_c w}{L_0} & \omega^2 & 0 \\ \frac{R_c w}{L_0 C_0 R_x} & 0 & \omega^2 \end{vmatrix}}{\Delta}$$

$$= \frac{\frac{2\zeta R_c w^2}{L_0} + \frac{R_c w \omega_0^2}{L_0 C_0 R_x} - \frac{R_c w^3}{L_0 C_0 R_x}}{\Delta}$$

$$C = \frac{\begin{vmatrix} 1 & 0 & 1 \\ 2\zeta & \frac{R_c w}{L_o} & 0 \\ \omega_0^2 & \frac{R_c w}{L_o C_o R_x} & \omega^2 \end{vmatrix}}{\Delta} = \frac{\frac{R_c w^3}{L_o} + \frac{2\zeta R_c w \zeta}{L_o C_o R_x} - \frac{R_c w \omega_0^2}{L_o}}{\Delta}$$

$$D = \frac{\begin{vmatrix} 1 & 0 & 0 \\ 2\zeta & \omega^2 & \frac{R_c w}{L_o} \\ \omega_0^2 & 0 & \frac{R_c w}{L_o C_o R_x} \end{vmatrix} + \begin{vmatrix} 2\zeta & 1 & 0 \\ \omega_0^2 & 2\zeta & \frac{R_c w}{L_o} \\ 0 & \omega_0^2 & \frac{R_c w}{L_o C_o R_x} \end{vmatrix}}{\Delta}$$

$$= \frac{\frac{R_c w^3}{L_o C_o R_x} + \frac{4\zeta^2 R_c w}{L_o C_o R_x} - \frac{2\zeta \omega_0^2 R_c w}{L_o} - \frac{R_c w \omega_0^2}{L_o C_o R_x}}{\Delta}$$

$$V_o(s) = \frac{AS}{(s^2 + \omega^2)} + \frac{B}{(s^2 + \omega^2)} + \frac{CS}{(s + \zeta)^2 + (\sqrt{\omega_0^2 - \zeta^2})^2} + \frac{D}{(s + \zeta)^2 + (\sqrt{\omega_0^2 - \zeta^2})^2}$$

$\zeta < \omega_0$

$$V_o(t) = \mathcal{L}^{-1}[V_o(s)] \quad (\text{Causal System})$$

$$= A \cos \omega t + \frac{B}{\omega} \sin \omega t + \frac{C e^{-\zeta t}}{\omega_0^2 - \zeta^2} \left\{ \frac{d}{dt} \left[\zeta \cos \sqrt{\omega_0^2 - \zeta^2} t + \sqrt{\omega_0^2 - \zeta^2} \sin \sqrt{\omega_0^2 - \zeta^2} t \right] \right. \\ \left. - 2\sqrt{\omega_0^2 - \zeta^2} \frac{d}{dt} \sin \sqrt{\omega_0^2 - \zeta^2} t \right\} - \frac{D e^{-\zeta t}}{\omega_0^2 - \zeta^2} \frac{d}{dt} \cos(\sqrt{\omega_0^2 - \zeta^2} t)$$

$$V_o(t) = A \cos \omega t + \frac{B}{\omega} \sin \omega t + \frac{C e^{-\zeta t}}{\omega_0^2 - \zeta^2} \left[-\zeta \sqrt{\omega_0^2 - \zeta^2} \sin \sqrt{\omega_0^2 - \zeta^2} t - (\omega_0^2 - \zeta^2) \cos \sqrt{\omega_0^2 - \zeta^2} t \right] \\ + \frac{D e^{-\zeta t} \sqrt{\omega_0^2 - \zeta^2}}{\omega_0^2 - \zeta^2} \sin \sqrt{\omega_0^2 - \zeta^2} t$$

E-11. Derivation of time response of differentiator for Sinwave input assuming perfect pole/zero cancellation.

$$V_o(s) = V_i(s) \cdot T_1(s) \cdot T_2(s) \quad \text{Linear System}$$

$$T_1(s) = \frac{100 SW_R}{(S + \omega_b)(S + \frac{1}{500C})} \quad (\text{Appendix B-1})$$

$$T_2(s) = \frac{R_C}{L_D} \frac{S + \frac{1}{C_0 R_X}}{(S^2 + S(\frac{1}{C_0 R_X} + \frac{R_D + 2R_E}{L_D}) + \frac{1}{L_D C_0})}$$

$$V_i(s) = \frac{\omega}{S^2 + \omega^2}$$

$$V_o(s) = \frac{\omega}{S^2 + \omega^2} \cdot \frac{100 SW_R}{(S + \omega_b)(S + \frac{1}{500C})} \cdot \frac{R_C}{L_D} \frac{(S + \frac{1}{C_0 R_X})}{[S^2 + S(\frac{1}{C_0 R_X} + \frac{R_D + 2R_E}{L_D}) + \frac{1}{L_D C_0}]}$$

Assuming perfect pole/zero cancellation and, to make life easier, a perfect wideband amplifier ($\omega_b \sim \infty$). The $V_o(s)$ expression can be simplified as

$$V_o(s) = \frac{100 R_C}{L_D} \left(\frac{\omega}{S^2 + \omega^2} \right) (S) \left(\frac{1}{S^2 + S(\frac{1}{C_0 R_X} + \frac{R_D + 2R_E}{L_D}) + \frac{1}{L_D C_0}} \right)$$

Partial fraction expansion

$$V_o(s) = \frac{100 R_C}{L_D} \left[\frac{AS + B}{S^2 + \omega^2} + \frac{CS + D}{S^2 + 2\zeta S + \omega_0^2} \right]$$

$$(As + \beta)(\xi^2 + \omega_0^2) + (Cs + D)(\xi^2 + \omega^2) = 0 \quad \dots$$

$$As^3 + (B + 2A\xi)s^2 + (2B\xi + Aw_0^2)s + Bw_0^2 + Cs^3 + Ds^2 - \omega^2 s + Dw^2 = ws$$

$$\begin{cases} A - c = 0 \\ 2\xi A + B + D = 0 \\ w_0^2 A + 2\xi B + w^2 C = ws \\ w_0^2 B + w^2 D = 0 \end{cases}$$

$$\Delta = \begin{vmatrix} 1 & 0 & 1 \\ 2\xi & w^2 & 0 \\ w_0^2 & 0 & w^2 \end{vmatrix} + \begin{vmatrix} 2\xi & 1 & 1 \\ w_0^2 & 2\xi & 0 \\ 0 & w_0^2 & w^2 \end{vmatrix} = (w^2 - w_0^2)^2 + (2\xi w)^2$$

$$A = \frac{\begin{vmatrix} 0 & 1 & 1 \\ w & 2\xi & 0 \\ 0 & w_0^2 & w^2 \end{vmatrix}}{\Delta} = \frac{ww_0^2 - w^3}{\Delta}$$

$$B = \frac{\begin{vmatrix} 2\xi & 0 & 1 \\ w_0^2 & w & 0 \\ 0 & 0 & w^2 \end{vmatrix} + \begin{vmatrix} 0 & 0 & 1 \\ w & w^2 & 0 \\ 0 & 0 & w \end{vmatrix}}{\Delta} = \frac{w^3 2\xi}{\Delta}$$

$$C = \frac{\begin{vmatrix} 1 & 0 & 1 \\ 2\xi & w & 0 \\ w_0^2 & 0 & w^2 \end{vmatrix}}{\Delta} = \frac{w^3 - ww_0^2}{\Delta}$$

$$D = \frac{\begin{vmatrix} 2\beta & 1 & 0 \\ \omega_0^2 & 2\beta & \omega \\ 0 & \omega_0^2 & 0 \end{vmatrix} + \begin{vmatrix} 1 & 0 & 0 \\ 2\beta & \omega^2 & \omega \\ \omega_0^2 & 0 & 0 \end{vmatrix}}{\Delta} = \frac{-2\beta\omega_0^2\omega}{\Delta}$$

$$\mathcal{L}^{-1}[V_o(s)] = \frac{100R_c}{L_o} \left[\frac{As}{s^2 + \omega^2} + \frac{B}{s + \beta} + \frac{Cs}{(s + \beta)^2 + (\sqrt{\omega^2 - \beta^2})^2} + \frac{D}{(s + \beta)^2 + (\sqrt{\omega^2 - \beta^2})^2} \right]$$

$$V_o(t) = \frac{100R_c}{L_o} \left\{ A e^{-\omega t} + \frac{\beta}{\omega} e^{-\beta t} + \frac{C}{\omega^2 - \beta^2} \left[-\sqrt{\omega^2 - \beta^2} \sin(\sqrt{\omega^2 - \beta^2})t - (\omega^2 - \beta^2) \cos(\sqrt{\omega^2 - \beta^2})t \right] + \frac{D e^{-\beta t} \sqrt{\omega^2 - \beta^2}}{\omega^2 - \beta^2} \sin(\sqrt{\omega^2 - \beta^2})t \right\}$$

After cancellation.

F. Common collector transistor equivalent circuit model:

Common collector transistor circuit is commonly used as buffer to isolate (reduce) the effect of output circuit effect (loading) on the input circuit. There are many ways of modelling a transistor circuit. The most common ones are Tee equivalent circuit, hybrid, hybrid II, charge control model and other variations. The model I am going to use is a variation of hybrid II model for small signal and low frequency applications. Small signal means the transistor is in linear regime. Low frequency means singal below 10 MHz.

PNP common collector model

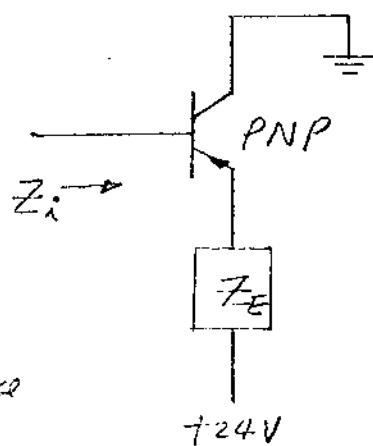

$$V_i = (\beta + 1)i_b Z_E + i_b h_{ie}$$

$$h_{ie} = r_b + (\beta + 1) r_e$$

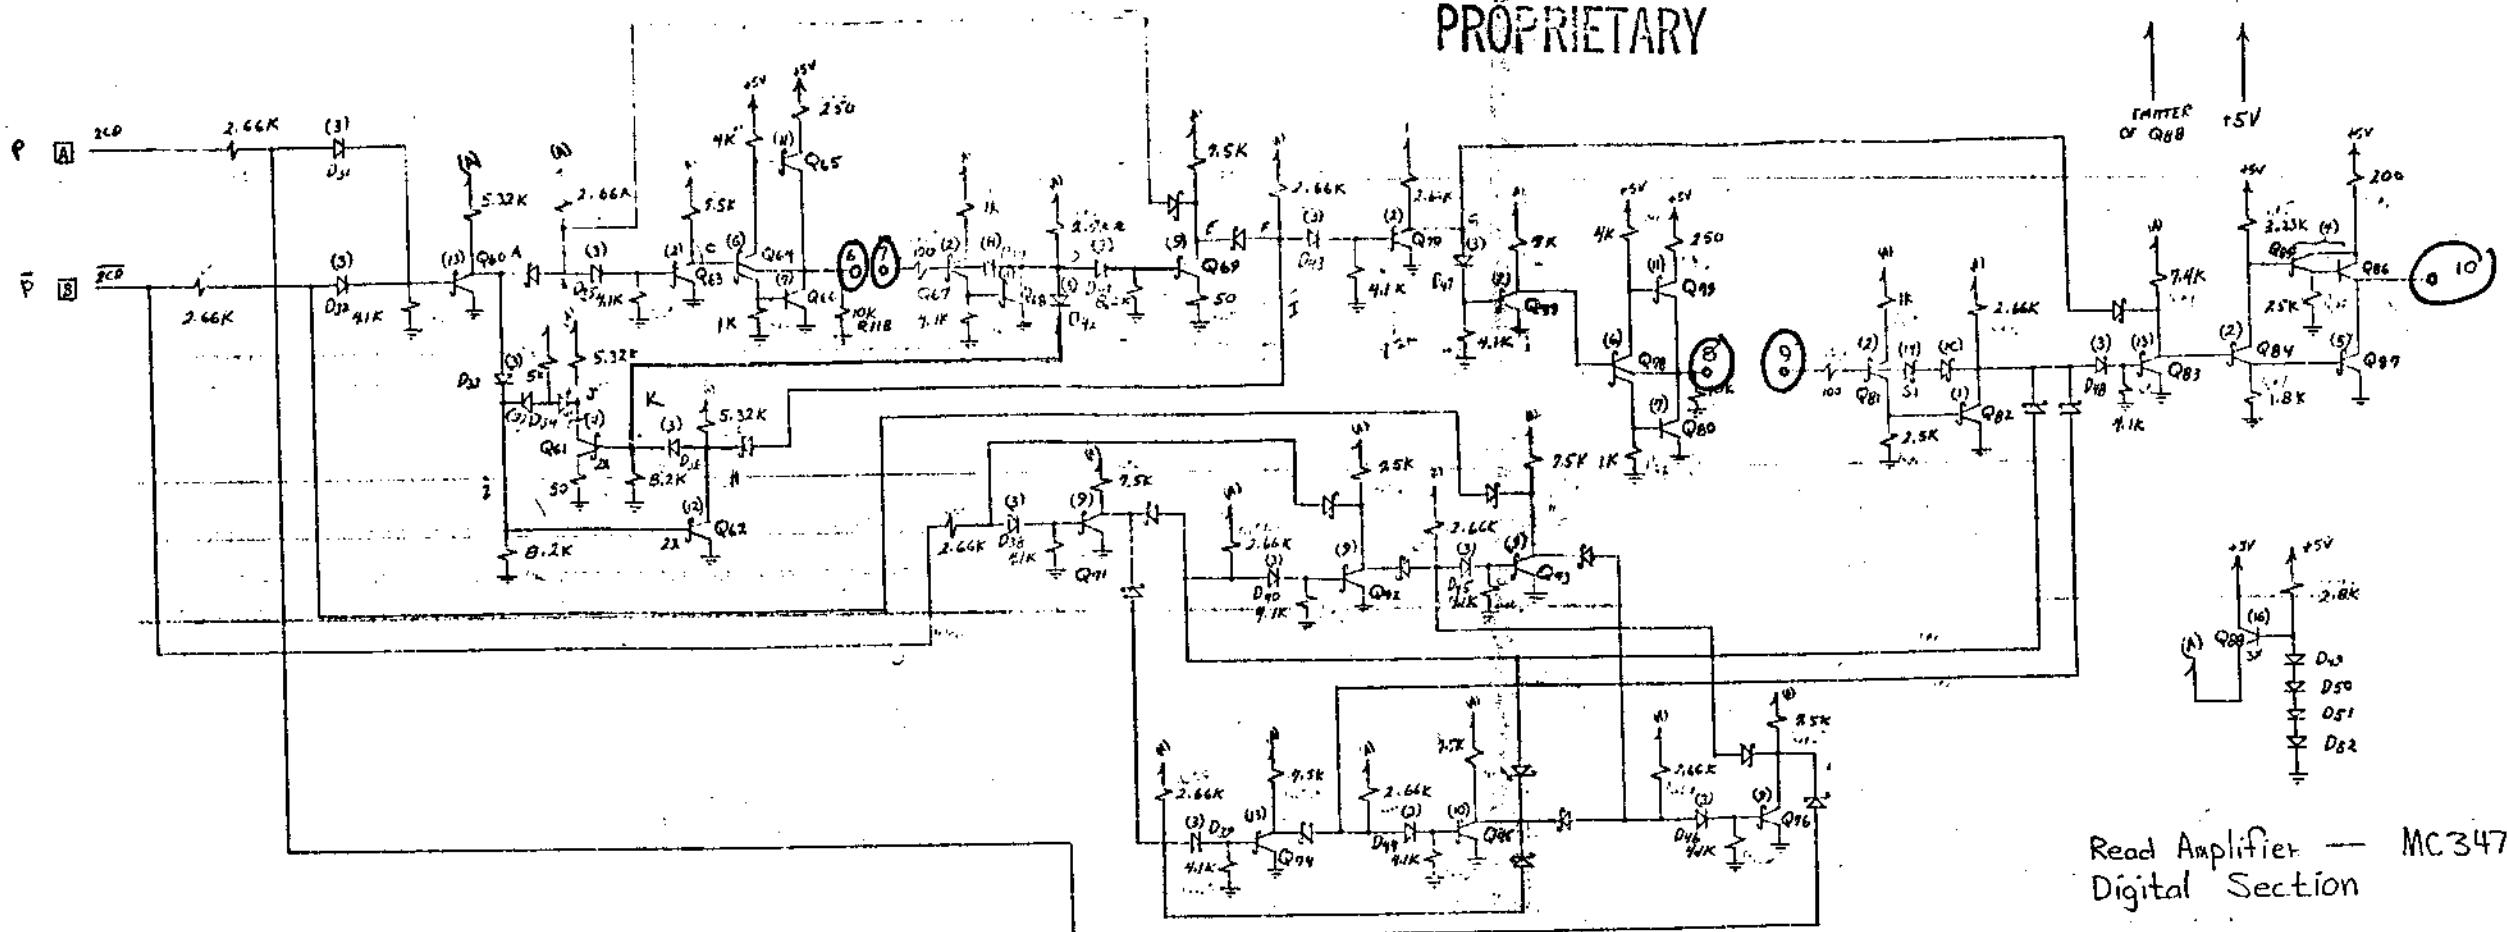

$$Z_i = \frac{V_i}{i_b} = (\beta + 1) Z_E + h_{ie}$$

$$\approx \beta Z_E$$

From the derivation, the input impedance of a common collector amplifier is βZ_E , where Z_E is the total effective impedance at the emitter leg.
