Thank you for your continued patronage of Mitsubishi Electric and our semiconductor products.

Semiconductor devices are a mainstay of the burgeoning electronics industry, where they are finding more and more applications, and meeting demands for increased sophistication and diversification of performance and function.

This data book has been compiled to be as complete as possible, including data on large-scale IC memories, single-chip microcomputers, peripheral LSIs for 16-bit parallel processing CPUs, speech synthesis LSIs and microcomputer development support equipment, with the addition of a variety of originally developed MOS LSI devices.

We hope you will let us know of any mistakes or omissions that come to your attention, and any suggestions you might have on improving the usefulness of this data book.

January, 1982

Kimio Sato, General Manager
Semiconductors Division
Mitsubishi Electric Corporation

ORDERING INFORMATION

FUNCTION CODE

Mitsubishi integrated circuits may be ordered using the following simplified alphanumeric type-codes which define the function of the ICs and the package style.

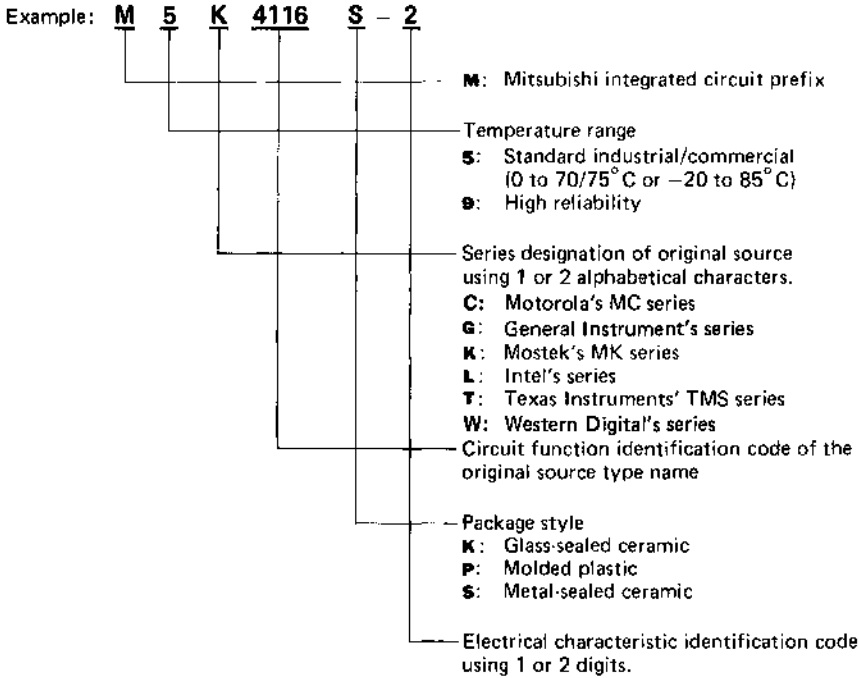

For Mitsubishi Original Products

Example: **M 5 89 81 S - 45**

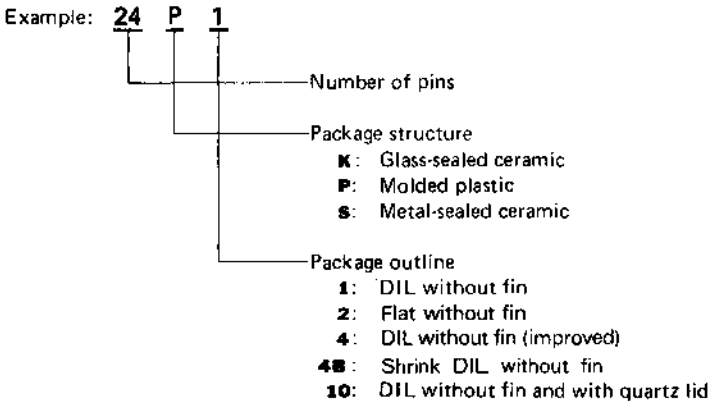

ORDERING INFORMATION

For Second Source Products

PACKAGE CODE

Package style may be specified by using the following simplified alphanumeric code.

TYPE 8P4 8-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 14P4 14-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 16K1 16-PIN GLASS-SEALED CERAMIC DIL

UNIT: mm

TYPE 16P4 16-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 16S1 16-PIN METAL-SEALED CERAMIC DIL

UNIT: mm

TYPE 18P4 18-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 18S1 18-PIN METAL-SEALED CERAMIC DIL

UNIT: mm

TYPE 20P4 20-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 22P1 22-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 24P1 24-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 24K10 24-PIN METAL-SEALED CERAMIC DIL WITH QUARTZ LID

UNIT: mm

TYPE 28P4 28-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 28K10 28-PIN METAL-SEALED CERAMIC DIL WITH QUARTZ LID

UNIT: mm

TYPE 40P1 40-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 40P4B 40-PIN SHRINK MOLDED PLASTIC DIL

UNIT: mm

TYPE 40S1 40-PIN METAL-SEALED CERAMIC DIL

UNIT: mm

TYPE 40S10 40-PIN METAL-SEALED CERAMIC DIL WITH QUARTZ LID

UNIT: mm

TYPE 42P1 42-PIN MOLDED PLASTIC DIL

UNIT: mm

TYPE 42P4B 42-PIN SHRINK MOLDED PLASTIC DIL

GENERAL

Semiconductor A material with resistivity usually in the range between metals and insulators, in which the electrical charge carrier concentration increases with increasing temperature range.

Extrinsic semiconductor A semiconductor with charge carrier concentration dependent upon impurities or other imperfections.

N-type semiconductor An extrinsic semiconductor in which the conduction electron density exceeds the mobile hole density.

P-type semiconductor An extrinsic semiconductor in which the mobile hole density exceeds the conduction electron density.

Junction A region of transition between semiconducting regions of different electrical properties.

PN junction A junction between P- and N-type semiconductor materials.

Depletion layer A region in which the mobile charge carrier density is insufficient to neutralize the net fixed charge density of donors and acceptors.

Breakdown (of a reverse-biased PN junction) A phenomenon, the initiation of which is observed as a transition from a state of dynamic resistance to a state of substantially lower dynamic resistance, for increasing the magnitude of a reverse current.

Semiconductor device A device whose essential characteristics are due to the flow of charge carriers within a semiconductor.

Reverse voltage The voltage across a junction or a diode when biased in the direction corresponding to the higher resistance.

Breakdown voltage The reverse voltage at which the reverse current through a junction becomes greater than a specified value.

Case temperature The temperature measured at a specified point on the case of a semiconductor device.

Storage temperature The temperature at which a semiconductor device is stored without any voltage applied.

INTEGRATED CIRCUITS

Microelectronics The concept of the construction and use of highly miniaturized electronic circuits.

Microcircuit A microelectronic device, having a high equivalent circuit-element and/or component density, which is considered as a single unit.

Note: A microcircuit may be a microassembly or an integrated (micro) circuit.

Integrated circuit A circuit in which a number of circuit elements are inseparably associated and electrically inter-

connected, so that, for the purpose of specification, testing, commerce and maintenance, it is considered indivisible.

Note: For this definition, a circuit element does not have an envelope or external connection and is not specified or sold as a separate item.

Integrated microcircuit A microcircuit in which a number of circuit elements are inseparably associated and electrically interconnected, so that, for the purpose of specification, testing, commerce and maintenance, it is considered indivisible.

Note 1: For this definition, a circuit element does not have an envelope or external connection and is not specified or sold as a separate item.

2: Where no misunderstanding is possible, the term integrated microcircuit may be abbreviated to integrated circuit.

3: Further qualifying terms may be used to describe the technique used in the manufacture of a specific integrated microcircuit.

Examples of the use of qualifying terms are:

semiconductor monolithic integrated circuit

semiconductor multichip integrated circuit

thin film integrated circuit

thick film integrated circuit

hybrid integrated circuit

Microassembly A microcircuit consisting of various components and/or integrated microcircuits which are constructed separately and which can be tested before being assembled and packaged.

Note 1: For this definition, a component has external connections and possibly an envelope as well, and it also can be specified and sold as a separate item.

2: Further qualifying terms may be used to describe the form of the components and/or the assembly techniques used in the construction of a specific microassembly.

Examples of use of qualifying terms are:

semiconductor multichip microassembly

discrete component microassembly

Integrated electronics The art and technology of the design, fabrication and use of integrated circuits.

Worst-case conditions (for a single characteristic) The values of the applied conditions which are individually chosen from within a specified range and together produce the most unfavorable value for a considered characteristic.

Note: Worst case conditions for different characteristics may be different.

DIGITAL INTEGRATED CIRCUITS

Digital signal The variation with time of a physical quantity that is used for the transmission of information or for information processing, and that has a finite number of nonoverlapping ranges of values.

Note 1: The physical quantity may be voltage, or current, or impedance, etc.

2: For convenience, each range of values can be represented by a single value, e.g. the nominal value.

Binary signal A digital signal with only two possible ranges of values.

Note: For convenience, each range of values can be represented by a single value—e.g., the nominal value.

Low range (of a binary signal) The range of least positive (most negative) levels of a binary signal.

Note: This range is often denoted by 'L-range,' and any level in the range by 'L-level.'

High range (of a binary signal) The range of most positive (least negative) levels of a binary signal.

Note: This range is often denoted by 'H-range,' and any level in the range by 'H-level.'

Digital circuit A circuit which is designed to operate by means of digital signals at the input(s) and at the output(s).

Note 1: In this definition, it is understood that 'inputs' and 'outputs' exclude static power supplies.

2: In some digital circuits—e.g., certain types of a stable circuits—the inputs need not exist.

Binary circuit A digital circuit designed to operate with binary signals.

Note: The pairs of ranges of values of the binary signals may be different at different terminals.

Input configuration (input pattern) (of a binary circuit) A combination of the L-levels and H-levels at the input terminals at a given instant.

Output configuration (output pattern) (of a binary circuit) A combination of the L-levels and H-levels at the output terminals at a given instant.

Note: When there is no possibility of ambiguity, the output configuration (output pattern) may be represented by the level (expressed as L-level or H-level) of the signal at a stated output terminal of the circuit (the reference output terminal).

Input terminal A terminal by means of which an applied signal may modify the output configuration (output pattern) of the circuit—either directly or indirectly—by modifying the ways in which the circuit reacts to signals at other terminals.

Combinatorial (digital) circuit A digital circuit in which there exists one, and only one, combination of the digital signals at the outputs for each possible combination of digital signals at the inputs.

Sequential (digital) circuit A digital circuit in which there exists at least one combination of the digital signals at the inputs for which there is more than one corresponding combination of the digital signals at the outputs.

Note: These combinations at the outputs are determined by previous history—e.g., as a result of internal memory or delay.

Elementary combinatorial circuit A binary combinatorial (digital) circuit which has only one output terminal, and in which the output signal accepts the value occurring only once in the function if, and only if, the signals applied to all the input terminals are either all in the H-range or all in the L-range.

Note 1: Because the output signal value (occurring only once in the function table) can lie either in the H-range or in the L-range, there are four types of elementary combinatorial circuits.

According to the assignment of the signal values L and H to the binary values 0 and 1 of Boolean algebra, the following logic operations can be realized by means of the four types of elementary combinatorial circuits: AND, OR, NAND, NOR.

2: Nonelementary combinatorial circuits can be formed by combining elementary combinatorial circuits or by combining elementary combinatorial circuits with inverters.

Function table A representation of the necessary or possible relations between the values of the digital signals at the inputs and the outputs of a digital circuit, these values of the digital signals being indicated either by using electrical values directly or by stating the electrical significance of the symbols—e.g., L and H for binary circuits. Generally, every column indicates the values of the digital signals at an input or at an output of the digital circuit; every row indicates the combination of values of the digital signals at the input(s) and the resulting values of the digital signals at the output(s); whenever the value of the digital signal at an output is not determined, it should be indicated by a question mark; whenever the value of a digital signal at an input has no influence, it should be indicated by the symbol L/H or X.

Truth table (for a relation between digital variables) A representation of the logic relationship between one or more independent digital variables and one or more dependent digital variables, by means of a table which, for each possible combination of the values of the independent variables, gives the appropriate values of the dependent variables.

Note: The distinction between 'function table' and 'truth table' is fundamentally necessary, because the same digital circuit may fulfil several different logic operations, according to the arbitrary assignment of the values of the digital variables to the values of the digital electrical quantities.

Input loading factor (of a bipolar digital circuit) A factor which indicates the ratio of the input current of a specified input terminal of a digital circuit to the input current of a particular circuit which is chosen as a reference load.

Note: The reference load should preferably be chosen in such a way that the input loading factor becomes an integer.

Output loading capability (of a bipolar digital circuit) A factor which indicates the ratio of the maximum output current of a specified output terminal of a digital circuit to the input current of a particular circuit which is chosen as a reference load.

Note: The reference load should preferably be chosen in such a way that the output loading capability becomes an integer.

Excitation An input configuration (input pattern), or change in input configuration (input pattern), that can cause the circuit to change its output configuration (output pattern), either directly, or in conjunction with an already existing state of preparedness; or put the circuit in a state of preparedness; or either cancel or modify an already existing state of preparedness.

Note 1: The repetition or reiteration of a given excitation will not necessarily produce the same effect.

2: In some cases, an excitation can also maintain an output configuration (output pattern) which it could have produced.

Expander circuit An auxiliary circuit which can be used to expand the number of inputs of equal influence of an associated circuit without modifying the function of the associated circuit.

Binary inverter A binary circuit which has only one input terminal and one output terminal, and in which a signal value L (or H) at the input produces a signal value H (or L) at the output.

Function (sequential) matrix A table having several inputs which gives the possible output configurations for each input configuration(s) and from which the output configuration(s) resulting from a transition from each individual input configuration to any other input configuration can be read directly.

Note: Where appropriate, a function (sequential) matrix may be completed by additional data or details concerning time conditions—e.g., transition times for one input level, delay time, duration of the input configuration to produce a desired new output configuration.

SEQUENTIAL CIRCUITS

Master-slave arrangement An arrangement of two bistable circuits such that one of them, called the 'slave,' reproduces the output configuration of the other circuit, called the 'master.' The transfer of information from the master to the slave is produced by means of an appropriate signal.

Register An arrangement of bistable circuits by means of which information may be accepted, stored and restituted.

Note: The register may form part of another memory and is of a specified capacity.

Shift Register A register that, by means of an appropriate control signal, can transfer information between consecutive bistable circuits with the sequence being preserved.

Counter A sequential circuit for storing numbers that permits such numbers to be incremented or decremented by a defined constant, including unity.

TIME INTERVALS BETWEEN INPUT SIGNALS

Setup time (t_{su}) (of a digital circuit) The time interval between the application of a signal which is maintained at a specified input terminal and a consecutive active transition at another specified input terminal.

Note 1: The setup time is measured between the instants at which the magnitudes of the two signals pass through specified values within the transition of the signal levels.

2: The setup time is the actual time between two events and may be insufficient to accomplish the setup. A minimum value is specified which is the shortest interval for which correct operation of the digital circuit is guaranteed.

3: The setup time may have a negative value, in which case the minimum limit for which correct operation of the digital circuit is guaranteed defines the longest interval between the active transition and the application of the other signal.

Hold time (t_h) (of a digital circuit) The time interval during which a signal is retained at a specified input terminal after an active transition occurs at another specified input terminal.

Note 1: The hold time is measured between the instants at which the magnitudes of the two signals pass through specified values within the transitions of the signal levels.

2: The hold time is the actual time between two events and may be insufficient to accomplish the intended result.

A minimum value is specified which is the shortest interval for which correct operation of the digital circuit is guaranteed.

3: The hold time may have a negative value, in which case the minimum limit for which correct operation of the digital circuit is guaranteed defines the longest interval between the change of the signal and the active transition.

Resolution time (t_{res}) (of a digital circuit) The time interval between the cessation of one input pulse and the commencement of the next input pulse applied to the same input terminal.

Note 1: The resolution time is measured between the instants at which the magnitude of the input signal passes through specified values within the transitions of the signal levels.

2: The resolution time is the actual time between two pulses and may be insufficient to ensure that both pulses are recognized. A minimum value is specified which is the shortest interval for which correct operation of the digital circuit is guaranteed.

SWITCHING TIMES OF BINARY CIRCUITS

High-level to low-level (low-level to high-level) propagation time (t_{PHL} and t_{PLH}) The time interval between specified reference points on the input and on the output pulses, when the output is going to the low (high) level and when the device is driven and loaded by typical devices of stated type.

Note: The mean value between the upper limit of the input low range and the lower limit of the input high range is generally used as the specified reference level.

High-level to low-level (low-level to high-level) delay time (t_{DHL} and t_{DLH}) The time interval between specified reference points on the input and on the output pulses, when the output is going to the low (high) level and when the device is driven and loaded by specified networks.

High-level to low-level (low-level to high-level) transition time (t_{THL} and t_{TLH}) The time interval between specified reference points on the edge of the output pulse when the output is going to the low (high) level and when a specified input signal is applied through a specified network and the output is loaded by another specified network.

INTEGRATED CIRCUIT MEMORIES

Memory cell (memory element) The smallest subdivision of a memory into which a unit of data has been or can be entered, in which it is or can be stored, and from which it can be retrieved.

Integrated circuit memory An integrated circuit consisting of memory cells (elements) and usually including associated circuits such as those for address selection, amplifiers, etc.

Read-only memory (ROM) A memory intended to be read only.

Note: Unless otherwise specified, the term "read-only memory" implies that the content is unalterable, and defined by its structure.

Fixed-programmed read-only memory A read-only memory in which the data contents of each cell (element) are determined during manufacture and are thereafter unalterable.

Mask-programmed read-only memory A fixed-programmed read-only memory in which the data contents of each cell (element) are determined during manufacture by the use of a mask.

Field-programmable read-only memory A read-only memory that, after being manufactured, can have the data content of each memory cell (element) altered.

Programmable read-only memory (PROM) A read-only memory that can have the data content of each memory cell (element) altered once only.

Reprogrammable read-only memory A read-only memory that can have the data content of each memory cell (element) altered more than once.

Read/write memory A memory in which each cell (element) may be selected by applying appropriate electrical input signals, and in which the stored data may be either: a) sensed at appropriate output terminals; or b) changed in response to other similar electrical input signals.

Static read/write memory A memory in which the data is retained in the absence of control signals.

Note 1: The words "read/write" may be omitted from the term when no misunderstanding will result.
 2: A static memory may use dynamic addressing or sensing circuits.

Dynamic read/write memory A memory in which the cells (elements) require the repetitive application of control signals in order to retain the data stored.

Note 1: The words "read/write" may be omitted from the term when no misunderstanding will result.
 2: Such repetitive application of the control signals is normally called a refresh operation.
 3: A dynamic memory may use static addressing or sensing circuits.
 4: This definition applies whether the control signals are generated inside or outside the integrated circuit.

Volatile memory A memory whose data content is lost when the power supply is disconnected.

Random-access memory (RAM) A memory that permits access to any of its address locations in any desired sequence.

MICROPROCESSOR INTEGRATED CIRCUITS

Microprocessor integrated circuit An integrated circuit capable of:

1. Accepting coded instructions at one or more terminals.
2. Carrying out, in accordance with the instructions received, all of:
 - a. the acceptance of coded data for processing and/or storage;
 - b. arithmetic and logical operations on the input data together with any relevant data stored in the microprocessor integrated circuit;
 - c. the delivery of coded data.
3. Accepting and/or delivering signals controlling and/or describing the operation or state of the microprocessor integrated circuit.

Note: The instructions may be fed in, built in, or held in an internal store.

Note: The definitions of terms described here are extracted from IEC publication 147-0. Some of the terms for integrated circuit memories and microprocessors are under consideration.

LETTER SYMBOLS FOR THE DYNAMIC PARAMETERS

1. INTRODUCTION

A system of letter symbols to be used to represent the dynamic parameters of integrated circuit memories and other sequential circuits especially for single-chip microcomputers, microprocessors and LSIs for peripheral circuits has been discussed internationally in the TC47 of the International Electrotechnical Committee (IEC). Finally the IEC has decided on the meeting of TC47 in February 1980 that this system of letter symbols will be a Central Office document and circulated to all countries to vote which means this system of letter symbols will be a international standard.

The system is applied in this LSI data book for the new products only. Future editions of this data book will be applied this system. The IEC document which describes "Letter symbols for dynamic parameters of sequential integrated circuits, including memories" is introduced below. In this data book, the dynamic parameters in the IEC document are applied to timing requirements and switching characteristics.

2. LETTER SYMBOLS

The system of letter symbols outlined in this document enables symbols to be generated for the dynamic parameters of complex sequential circuits, including memories, and also allows these symbols to be abbreviated to simple mnemonic symbols when no ambiguity is likely to arise.

2.1. General Form

The dynamic parameters are represented by a general symbol of the form:

$$t_{A(BC-DC)F} \dots\dots\dots (1)$$

where :

Subscript A indicates the type of dynamic parameter being represented, for example; cycle time, setup time, enable time, etc.

Subscript B indicates the name of the signal or terminal for which a change of state or level (or establishment of a state or level) constitutes a signal event assumed to occur first, that is, at the beginning of the time interval. If this event actually occurs last, that is, at the end of the time interval, the value of the time interval is negative.

Subscript C indicates the direction of the transition and/or the final state or level of the signal represented by B. When two letters are used, the initial state or level is also indicated.

Subscript D indicates the name of the signal or terminal for which a change of state or level (or establishment of a state or level) constitutes a signal event assumed to occur last, that is, at the end of the time interval. If this event actually occurs first, that is, at the beginning of the time interval, the value of the time interval is negative.

Subscript E indicates the direction of the transition and/or the final state or level of the signal represented by D. When two letters are used, the initial state or level is also indicated.

Subscript F indicates additional information such as mode of operation, test conditions, etc.

Note 1: Subscripts A to F may each consists of one or more letters.

2: Subscripts D and F are not used for transition times

3: The "-" in the symbol (1) above is used to indicate "to", hence the symbol represents the time interval from signal event B occurring to signal event D occurring, and it is important to note that this convention is used for all dynamic parameters including hold times. Where no misunderstanding can occur the hyphen may be omitted.

2.2. Abbreviated Form

The general symbol given above may be abbreviated when no misunderstanding is likely to arise. For example to :

$$t_{A(B-D)}$$

or $t_{A(B)}$

or $t_{A(D)}$ — often used for hold times

or t_{AF} — no brackets are used in this case

or t_A

or t_{BC-DE} — often used for unclassified time intervals

2.3. Allocation of Subscripts

In allocating letter symbols for the subscripts, the most commonly used subscripts are given single letters where practicable and those less commonly used are designated by up to three letters. As far as possible, some form of mnemonic representation is used. Longer letter symbols may be used for specialised signals or terminals if this aids understanding.

3. SUBSCRIPT A (For Type of Dynamic Parameter)

The subscript A represents the type of dynamic parameter to be designated by the symbol and, for memories, the parameters may be divided into two classes :

- a) those that are timing requirements for the memory and

LETTER SYMBOLS FOR THE DYNAMIC PARAMETERS

b) those that are characteristics of the memory.
 The letter symbols so far proposed for memory circuits are listed in sub-clauses 3.1 and 3.2 below.
 All subscripts A should be in lower-case.

Erase	ER
Output enable	G
Program	PR
Data output	Q
Read	R
Row address	RA
Row address strobe	RAS
Refresh	RF
Read/Write	RW
Chip select	S
Write (write enable)	W

3.1. Timing Requirements

The letter symbols for the timing requirements of semiconductor memories are as follows :

Term	Subscript
Cycle time	c
Time interval between two signal events	d
Fall time	f
Hold time	h
Precharging time	pc
Rise time	r
Recovery time	rec
Refresh time interval	rf
Setup time	su
Transition time	t
Pulse duration (width)	w

Note 1: In the letter symbols for time intervals, bars over the subscripts, for example $\bar{C}AS$, should not be used.

- It should be noted, when further letter symbols are chosen, that the subscript should not end with H, K, V, X, or Z (See clause 5)
- If the same terminal, or signal, can be used for two functions (for example Data input/output, Read/Write) the waveform should be labelled with the dual function, if appropriate, but the symbols for the dynamic parameters should include only that part of the subscript relevant to the parameter.

3.2. Characteristics

The letter symbols for the dynamic characteristics of semiconductor memories are as follows :

Characteristic	Subscript
Access time	a
Disable time	dis
Enable time	en
Propagation time	p
Recovery time	rec
Transition time	t
Valid time	v

Note: Recovery time for use as a characteristic is limited to sense recovery time.

4. SUBSCRIPTS B AND D (For Signal Name or Terminal Name)

The letter symbols for the signal name or the name of the terminal are as given below.
 All subscripts B and D should be in upper-case.

Signal or terminal	Subscript
Address	A
Clock	C
Column address	CA
Column address strobe	CAS
Data input	D
Data input/output	DQ
Chip enable	E

5. SUBSCRIPTS C AND E (For Transition of Signal)

The following symbols are used to represent the level or state of a signal :

Transition of signal	Subscript
High logic level	H
Low logic level	L
Valid steady-state level (either low or high)	V
Unknown, changing, or 'don't care' level	X
High-impedance state of three-state output	Z

The direction of transition is expressed by two letters, the direction being from the state represented by the first letter to that represented by the second letter, with the letters being as given above.

When no misunderstanding can occur, the first letter may be omitted to give an abbreviated symbol for subscripts C and E as indicated below.

All subscripts C and E should be in upper-case.

Examples	Subscript	
	Full	Abbreviated
Transition from high level to low level	HL	L
Transition from low level to high level	LH	H
Transition from unknown or changing state to valid state	XV	V
Transition from valid state to unknown or changing state	VX	X
Transition from high-impedance state to valid state	ZV	V

Note: Since subscripts C and E may be abbreviated, and since subscripts B and D may contain an indeterminate number of letters, it is necessary to put the restriction on the subscripts B and D that they should not end with H, L, V, X, or Z, so as to avoid possible confusion.

LETTER SYMBOLS FOR THE DYNAMIC PARAMETERS

6. SUBSCRIPT F (For Additional Information)

If necessary, subscript F is used to represent any additional qualification of the parameter such as mode of operation, test conditions, etc. The letter symbols for subscript F are given below.

Subscript F should be in upper-case.

Modes of operation	Subscript
Power-down	PD
Page-mode read	PGR
Page-mode write	PGW
Read	R
Refresh	RF
Read-modify-write	RMW
Read-write	RW
Write	W

FOR DIGITAL INTEGRATED CIRCUITS

New symbol	Former symbol	Parameter - definition
C_i		Input capacitance
C_o		Output capacitance
$C_{i/o}$		Input/output terminal capacitance
$C_i(\phi)$		Input capacitance of clock input
f		Frequency
$f(\phi)$		Clock frequency
I		Current—the current into an integrated circuit terminal is defined as a positive value and the current out of a terminal is defined as a negative value
I_{BB}		Supply current from V_{BB}
$I_{BB}(AV)$		Average supply current from V_{BB}
I_{CC}		Supply current from V_{CC}
$I_{CC}(AV)$		Average supply current from V_{CC}
$I_{CC}(PD)$		Power-down supply current from V_{CC}
I_{DD}		Supply current from V_{DD}
$I_{DD}(AV)$		Average supply current from V_{DD}
I_{GG}		Supply current from V_{GG}
$I_{GG}(AV)$		Average supply current from V_{GG}
I_i		Input current
I_{IH}		High-level input current—the value of the input current when V_{OH} is applied to the input considered
I_{IL}		Low-level input current—the value of the input current when V_{OL} is applied to the input considered
I_{OH}		High-level output current—the value of the output current when V_{OH} is applied to the output considered
I_{OL}		Low-level output current—the value of the output current when V_{OL} is applied to the output considered
I_{OZ}		Off-state (high-impedance state) output current—the current into an output having a three-state capability with input condition so applied that it will establish according to the product specification, the off (high-impedance) state at the output
I_{OZH}		Off state (high impedance state) output current, with high-level voltage applied to the output
I_{OZL}		Off-state (high-impedance state) output current, with low-level voltage applied to the output
I_{OS}		Short circuit output current
I_{SS}		Supply current from V_{SS}
P_d		Power dissipation
N_{EW}		Number of erase/write cycles
N_{RA}		Number of read access unrefreshed
R_i		Input resistance
R_L		External load resistance
R_{OFF}		Off-state output resistance
R_{ON}		On-state output resistance
t_a		Access time—the time interval between the application of a specified input pulse during a read cycle and the availability of valid data signal at an output
$t_a(A)$	$t_a(AO)$	Address access time—the time interval between the application of an address input pulse and the availability of valid data signals at an output
$t_a(CAS)$		Column address strobe access time
$t_a(E)$	$t_a(OE)$	Chip enable access time
$t_a(Q)$	$t_a(OE)$	Output enable access time
$t_a(PR)$		Data access time after program
$t_a(RAS)$		Row address strobe access time
$t_a(S)$	$t_a(OS)$	Chip select access time
t_C		Cycle time
t_{CR}	$t_C(RC)$	Read cycle time—the time interval between the start of a read cycle and the start of the next cycle
t_{CRF}	$t_C(REF)$	Refresh cycle time—the time interval between successive signals that are intended to restore the level in a dynamic memory cell to its original level
t_{CPG}	$t_C(PG)$	Page-mode cycle time
t_{CRMW}	$t_C(RMR)$	Read-modify-write cycle time—the time interval between the start of a cycle in which the memory is read and new data is entered, and the start of the next cycle
t_{CW}	$t_C(WR)$	Write cycle time—the time interval between the start of a write cycle and the start of the next cycle

New symbol	Former symbol	Parameter-definition
t_d		Delay time—the time between the specified reference points on two pulses
$t_d(\phi)$		Delay time between clock pulses—e.g., symbolgy, delay time, clock 1 to clock 2 or clock 2 to clock 1
$t_d(\text{CAS-RAS})$		Delay time, column address strobe to row address strobe
$t_d(\text{CAS-W})$	$t_d(\text{CAS-WR})$	Delay time, column address strobe to write
$t_d(\text{RAS-CAS})$		Delay time, row address strobe to column address strobe
$t_d(\text{RAS-W})$	$t_d(\text{RAS-WR})$	Delay time, row address strobe to write
$t_{dis}(\text{R-Q})$	$t_{dis}(\text{R-DA})$	Output disable time after read
$t_{dis}(\text{S})$	$t_{PXZ}(\text{CS})$	Output disable time after chip select
$t_{dis}(\text{W})$	$t_{PXZ}(\text{WR})$	Output disable time after write
t_{D-H}		High level to low level delay time
t_{DLH}		Low level to high-level delay time
$t_{en}(\text{A-Q})$	$t_{PZV}(\text{A-DQ})$	Output enable time after address
$t_{en}(\text{H-Q})$	$t_{PZV}(\text{R-DQ})$	Output enable time after read
$t_{en}(\text{S-Q})$	$t_{PZX}(\text{CS-DQ})$	Output enable time after chip select
t_f		Fall time
t_h		Hold time—the interval time during which a signal at a specified input terminal after an active transit on occurs at another specified input terminal
$t_h(\text{A})$	$t_h(\text{AD})$	Address hold time
$t_h(\text{A-E})$	$t_h(\text{AD-CE})$	Chip enable hold time after address
$t_h(\text{A-PR})$	$t_h(\text{AD-PRO})$	Program hold time after address
$t_h(\text{CAS-DA})$		Column address hold time after column address strobe
$t_h(\text{CAS-D})$	$t_h(\text{CAS-DA})$	Data-in hold time after column address strobe
$t_h(\text{CAS-Q})$	$t_h(\text{CAS-OUT})$	Data-out hold time after column address strobe
$t_h(\text{CAS-RAS})$		Row address strobe hold time after column address strobe
$t_h(\text{CAS-W})$	$t_h(\text{CAS-WR})$	Write hold time after column address strobe
$t_h(\text{D})$	$t_h(\text{DA})$	Data-in hold time
$t_h(\text{D-PR})$	$t_h(\text{DA-PRO})$	Program hold time after data-in
$t_h(\text{E})$	$t_h(\text{CE})$	Chip enable hold time
$t_h(\text{E-D})$	$t_h(\text{CE-DA})$	Data-in hold time after chip enable
$t_h(\text{E-Q})$	$t_h(\text{CE-QE})$	Output enable hold time after chip enable
$t_h(\text{R})$	$t_h(\text{RD})$	Read hold time
$t_h(\text{RAS-CA})$		Column address hold time after row address strobe
$t_h(\text{RAS-CAS})$		Column address strobe hold time after row address strobe
$t_h(\text{RAS-D})$	$t_h(\text{RAS-DA})$	Data-in hold time after row address strobe
$t_h(\text{RAS-W})$	$t_h(\text{RAS-WR})$	Write hold time after row address strobe
$t_h(\text{S})$	$t_h(\text{CS})$	Chip select hold time
$t_h(\text{W})$	$t_h(\text{WH})$	Write hold time
$t_h(\text{W-CAS})$	$t_h(\text{WR-CAS})$	Column address strobe hold time after write
$t_h(\text{W-D})$	$t_h(\text{WH-DA})$	Data-in hold time after write
$t_h(\text{W-RAS})$	$t_h(\text{WR-RAS})$	Row address hold time after write
t_{PHL}		High-level to low-level propagation time
t_{PLH}		Low level to high-level propagation time
t_r		Rise time
$t_{rec}(\text{W})$	t_{wr}	Write recovery time—the time interval between the termination of a write pulse and the initiation of a new cycle
$t_{rec}(\text{PD})$	$t_r(\text{PD})$	Power down recovery time
t_{su}		Setup time—the time interval between the application of a signal which is maintained at a specified input terminal and a consecutive active transition at another specified input terminal
$t_{su}(\text{A})$	$t_{su}(\text{AD})$	Address setup time
$t_{su}(\text{A-E})$	$t_{su}(\text{AD-CE})$	Chip enable setup time before address
$t_{su}(\text{A-W})$	$t_{su}(\text{AD-WR})$	Write setup time before address
$t_{su}(\text{CA-RAS})$		Row address strobe setup time before column address

MITSUBISHI LSIs

SYMBOLGY

New symbol	Former symbol	Parameter—definition
$t_{su}(D)$	$t_{su}(DA)$	Data-in setup time
$t_{su}(D-E)$	$t_{su}(DA-CE)$	Chip enable setup time before data-in
$t_{su}(D-W)$	$t_{su}(DA-WR)$	Write setup time before data-in
$t_{su}(E)$	$t_{su}(CE)$	Chip enable setup time
$t_{su}(E-P)$	$t_{su}(CE-P)$	Precharge setup time before chip enable
$t_{su}(G-E)$	$t_{su}(OE-CE)$	Chip enable setup time before output enable
$t_{su}(P-E)$	$t_{su}(P-CE)$	Chip enable setup time before precharge
$t_{su}(PD)$		Power-down setup time
$t_{su}(R)$	$t_{su}(RD)$	Read setup time
$t_{su}(R-CAS)$	$t_{su}(RA-CAS)$	Column address strobe setup time before read
$t_{su}(RA-CAS)$		Column address strobe setup time before row address
$t_{su}(S)$	$t_{su}(CS)$	Chip select setup time
$t_{su}(S-W)$	$t_{su}(CS-WR)$	Write setup time before chip select
$t_{su}(W)$	$t_{su}(WR)$	Write setup time
t_{THL}		High-level to low-level transition time
t_{TLH}		Low-level to high-level transition time
$t_v(A)$	$t_{dv}(AD)$	Data valid time after address
$t_v(E)$	$t_{dv}(CE)$	Data valid time after chip enable
$t_v(E)PR$	$t_v(OE)PR$	Data valid time after chip enable in program mode
$t_v(O)$	$t_v(OE)$	Data valid time after output enable
$t_v(PR)$		Data valid time after program
$t_v(S)$	$t_v(CS)$	Data valid time after chip select
t_w		Pulse width (pulse duration) the time interval between specified reference points on the leading and trailing edges of the waveforms
$t_w(E)$	$t_w(CE)$	Chip enable pulse width
$t_w(EH)$	$t_w(CEH)$	Chip enable high pulse width
$t_w(EL)$	$t_w(ELL)$	Chip enable low pulse width
$t_w(PR)$		Program pulse width
$t_w(R)$	$t_w(RD)$	Read pulse width
$t_w(S)$	$t_w(CS)$	Chip select pulse width
$t_w(W)$	$t_w(WR)$	Write pulse width
$t_w(\phi)$		Clock pulse width
T_a		Ambient temperature
T_{opr}		Operating temperature
T_{stg}		Storage temperature
V_{BB}		V_{BB} supply voltage
V_{CC}		V_{CC} supply voltage
V_{DD}		V_{DD} supply voltage
V_{GG}		V_{GG} supply voltage
V_i		Input voltage
V_{IH}		High-level input voltage—the value of the permitted high-state voltage at the input
V_{IL}		Low-level input voltage—the value of the permitted low-state voltage at the input
V_O		Output voltage
V_{OH}		High-level output voltage—the value of the guaranteed high-state voltage range at the output
V_{OL}		Low-level output voltage—the value of the guaranteed low-state voltage range at the output
V_{SS}		V_{SS} supply voltage

QUALITY ASSURANCE AND RELIABILITY TESTING

1

1. PLANNING

In recent years, advances in integrated circuits have been rapid, with increasing density and speed accompanied by decreasing cost. Because of these advances, it is now practical and economically justifiable to use these devices in systems of greater complexity and in which they were previously considered too expensive. All of these advances add up to increased demand.

We at Mitsubishi foresaw this increased demand and organized our production facilities to meet it. We also realized that simply increasing production to meet the demand was not enough and that positive steps would have to be taken to assure the reliability of our products.

This realization resulted in development of our Quality Assurance System. The system has resulted in improved products, and Mitsubishi is able to supply its customers' needs with ICs of high reliability and stable quality. This system is the key to future planning for improved design, production and quality assurance.

2. QUALITY ASSURANCE SYSTEM

The Quality Assurance System imposes quality controls on Mitsubishi products from the initial conception of a new product to the final delivery of the product to the customer. A diagram of the total system is shown in Fig. 1. For ease of understanding, the system is divided into three stages.

2.1 Quality Assurance in the Design Stage

The characteristics of the breadboard devices are carefully checked to assure that all specifications are met. Standard integrated circuits and high-quality discrete components are used. During the design stage, extensive use is made of a sophisticated CAD program, which is updated to always include the latest state-of-the-art techniques.

2.2 Quality Assurance in the Limited-Manufacturing Stage

Rigid controls are maintained on the environment, incoming material and manufacturing equipment such as tools and test equipment. The products and materials used are subjected to stringent tests and inspections as they are manufactured. Wafer production is closely monitored.

Finally, a tough quality assurance test and inspection is made before the product is released for delivery to a customer. This final test includes a complete visual inspection and electrical characteristics tests. A sampling technique is used to conduct tests under severe operating conditions to assure that the products meet reliability specifications.

2.3 Quality Assurance in the Full Production Stage

Full production of a product is not started until it has been confirmed that it can be manufactured to meet quality and reliability specifications. The controls, tests and inspection

procedures developed in §2.2 are continued. The closest monitoring assures that they are complied with.

3. RELIABILITY CONTROL

3.1 Reliability Tests

The newly established Reliability Center for Electronic Components of Japan has established a qualification system for electronic components. Reliability test methods and procedures are developed to mainly meet MIL-STD-883 and JIS C 7022 specifications. Details of typical tests used on Mitsubishi ICs are shown in Table 1.

Table 1 Typical reliability test items and conditions

Group	Item	Test condition
1	High temperature operating life	Maximum operating ambient temperature 1000h
	High temperature storage life	Maximum storage temperature 1000h
	Humidity (steady state) life	65°C 95%RH 500h
2	Soldering heat	260°C 10s
	Thermal shock	0~100°C 15 cycles, 10min/cycle
	Temperature cycle	Minimum to maximum storage temperature, 10 cycles of 1h/cycle
3	Soldering	230°C, 5s, use rosin flux
	Lead integrity	Tension 340g 30s Bending stress 225g +30°, 3 times
	Vibration	20G X, Y, Z each direction, 4 times 100~2000Hz 4 min/cycle
	Shock	1500G, 0.5ms in X ₁ , Y ₁ and Z ₁ direction, 5 times
	Constant acceleration	20000G Y ₁ direction 1 min

3.2 Failure Analysis

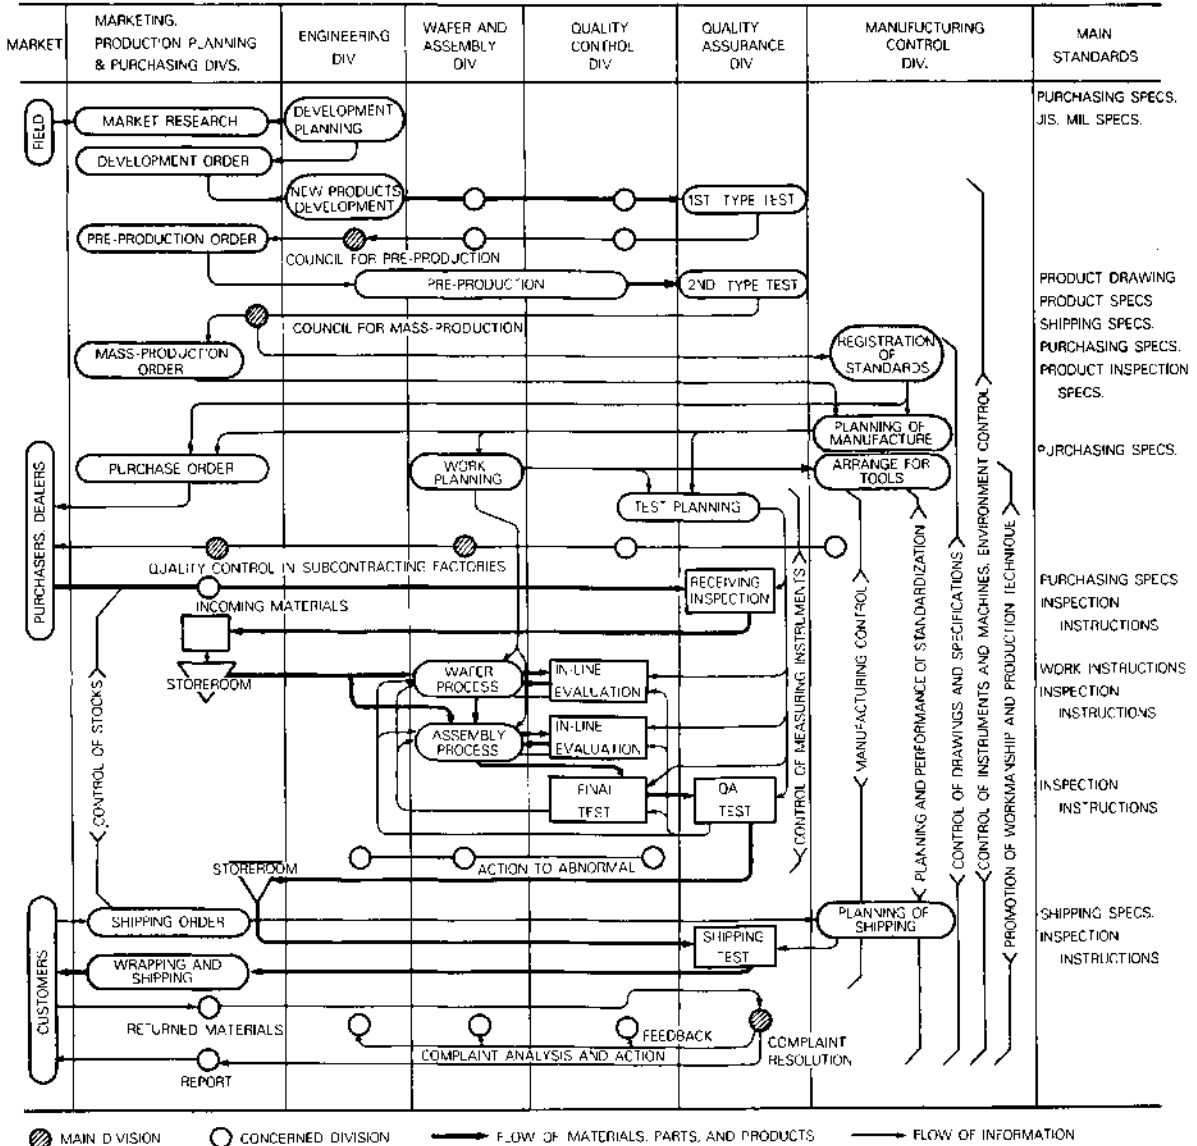

Devices that have failed during reliability or acceleration tests are analyzed to determine the cause of failure. This information is fed back to the process engineering section and manufacturing section so that improvements can be made to increase reliability. A summary of failure analysis procedures is shown in Table 2.

Table 2 Summary of failure analysis procedures

Step	Description
1. External examination	<ul style="list-style-type: none"> ○ Inspection of leads, plating, soldering and welding ○ Inspection of materials, sealing, package and marking ○ Visual inspection of other items of the specifications ○ Use of stereo microscopes, metallurgical microscopes, X ray photographic equipment, fine leakage and gross leakage testers in the examination
2. Electrical tests	<ul style="list-style-type: none"> ○ Checking for open circuits, short circuits and parametric degradation by electrical parameter measurement ○ Observation of characteristics by a synchroscope or a curve tracer and checking of important physical characteristics by electrical characteristics ○ Stress tests such as environmental or life tests, if required
3. Internal examination	<ul style="list-style-type: none"> ○ Removal of the cover of the device, the optical inspection of the internal structure of the device ○ Checking of the silicon chip surface ○ Measurement of electrical characteristics by probes, if applicable ○ Use of SEM XMA and infrared microscanner if required
4. Chip analysis	<ul style="list-style-type: none"> ○ Use of metallurgical analysis techniques to supplement analysis of the internal examination ○ Slicing for cross-sectional inspection ○ Analysis of oxide film defects ○ Analysis of diffusion defects

QUALITY ASSURANCE AND RELIABILITY TESTING

4. TYPICAL RESULTS OF RELIABILITY TESTS AND FAILURE ANALYSES

4.1 Results of Reliability Test

Formerly, sufficient reliability for memory MOS LSIs was obtained by using metal-sealed ceramic packages, but with the development of high-reliability plastic molding technology, production has been shifted to plastic molded memory MOS LSIs.

The following tests are performed:

1. Operating life test: Durability is tested at high temperature under operating state conditions by applying clock pulse inputs as shown in Fig. 2.
2. DC biased test: Durability is tested at high temperature biasing DC voltage, as shown in Fig. 3.
3. High temperature storage: The durability of devices stored at high temperatures is tested.

Typical results of memory MOS LSI life tests are shown in Table 3. The failure rate computed from this reliability data using an appropriate acceleration factor is 0.1 FIT or less (1 FIT = 10^{-9} /hour) per bit, about the same as, or less than, for core memories.

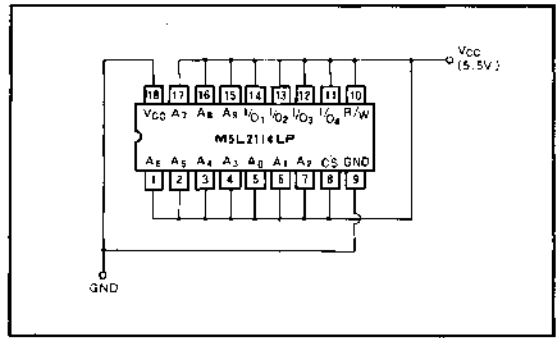

Fig. 3 DC biased test procedure (for M5L2114 LP 4K-bit static RAM)

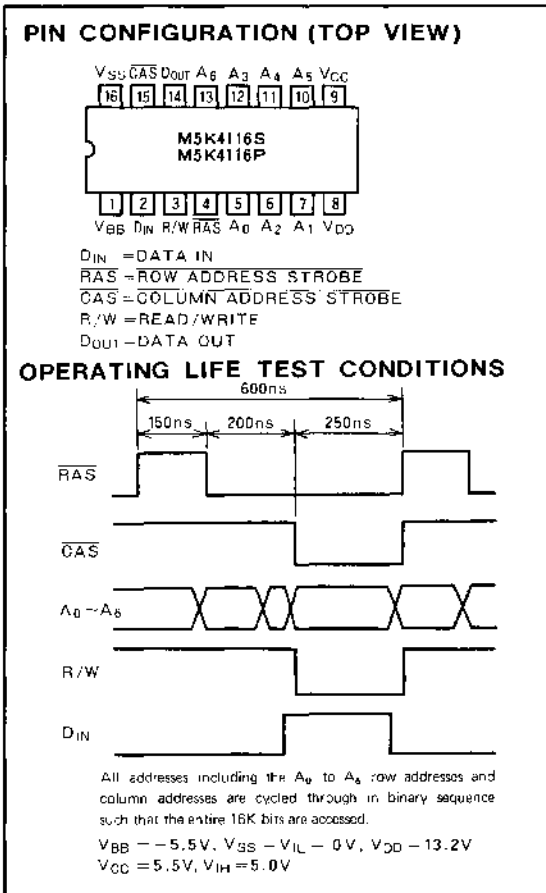

Fig. 2 Operating life test procedure (for M5K4116 P, S 16K-bit dynamic RAM)

QUALITY ASSURANCE AND RELIABILITY TESTING

Table 3 Examples of Endurance Test Results

Type No.	Package	Test category		Number of samples	Component hours	Number of failures	Remarks
M5K 4164S	16-pin metal-sealed ceramic DIL	Operating life	125°C	350	350,000	1	Functional failure
		High-temperature storage	150°C	150	150,000	0	
M5K 4116P	16-pin plastic molded DIL	Operating life	125°C	334	334,000	0	
		DC biased	125°C	88	132,000	0	
		High-temperature storage	150°C	132	132,000	0	
M58725P	24-pin plastic-molded DIL	Operating life	125°C	114	114,000	0	
		High-temperature storage	150°C	38	38,000	0	
M5L 2114LP	18-pin plastic-molded DIL	Operating life	125°C	176	198,000	0	
		DC biased	125°C	22	22,000	0	
		High-temperature storage	150°C	89	132,000	0	
M58981P	18-pin plastic-molded DIL	Operating life	125°C	110	110,000	0	
		DC biased	125°C	22	22,000	0	
		High-temperature storage	150°C	44	66,000	0	
M5L 5101LP	22-pin plastic molded DIL	Operating life	125°C	444	544,000	1	Functional failure
		DC biased	125°C	94	94,000	0	
		High-temperature storage	150°C	94	94,000	0	
M5L 2716K	24-pin metal-sealed ceramic DIL with quartz lid	Operating life	125°C	274	362,000	0	
		High-temperature storage	150°C	66	88,000	0	
M5L 2732K	24-pin metal-sealed ceramic DIL with quartz lid	Operating life	125°C	264	308,000	0	
		High-temperature storage	150°C	44	66,000	0	

Table 4 Examples of Environmental Test Results

Test category		Test conditions		Type No.	Number of samples	Number of failures	Remarks
Thermal environment	Soldering heat	260°C, 10s		M5K4116P M5L2114LP M5L5101LP	330	0	
	Thermal shock	-40°C~125°C, 10min/cycle, 15 cycles					
	Temperature cycling	-65°C~150°C, 1h/cycle, 100 cycles

QUALITY ASSURANCE AND RELIABILITY TESTING

5. CONCLUSION

Mitsubishi Electric's Quality Assurance System is being expanded to provide stronger emphasis on the following points:

1. Establishment of quality and reliability levels that satisfy customers' requirements.
2. Expansion of the reliability tests of wafers and assembly processes for better evaluation, and standardization of circuit and design rules.
3. Establishment of procedures for speeding up the introduction of new technology and improved methods that raise reliability and to improve the accelerated life tests for better failure analysis.
4. Establishment of a system for collecting data on failures in the field, which will then be analyzed to develop improved methods for increasing reliability.

We welcome and appreciate the cooperation of our customers in developing design specifications, establishing quality levels, controlling incoming inspections, developing assembly and adjusting processes and collecting field data. Mitsubishi is anxious to work with its customers to develop ICs of increased reliability that meet their requirements.

PRECAUTIONS IN HANDLING MOS ICs

A MOS transistor has a very thin oxide insulator under the gate electrode on the silicon substrate. It is operated by altering the conductance (g_m) between source and drain to control mobile charges in the channel formed by the applied gate voltage.

If a high voltage were applied to a gate terminal, the insulator-film under the gate electrode could be destroyed, and all Mitsubishi MOS IC/LSIs contain internal protection circuits at each input terminal to prevent this. It is inherently necessary to apply reverse bias to the P-N junctions of a MOS IC/LSI.

Under certain conditions, however, it may be impossible to completely avoid destruction of the thin insulator-film due to the application of unexpectedly high voltage or thermal destruction due to excessive current from a forward biased P-N junction. The following recommendations should be followed in handling MOS devices.

1. KEEPING VOLTAGE AND CURRENT TO EACH TERMINAL BELOW MAXIMUM RATINGS

1. The recommended ranges of operating conditions provide adequate safety margins. Operating within these limits will assure maximum equipment performance and quality.
2. Forward bias should not be applied to any terminal since excessive current may cause thermal destruction.
3. Output terminals should not be connected directly to the power supply. Short-circuiting of a terminal to a power supply having low impedance may cause burn-out of the internal leads or thermal destruction due to excessive current.

2. KEEPING ALL TERMINALS AT THE SAME POTENTIAL DURING TRANSPORT AND STORAGE

When MOS IC/LSIs are not in use, both input and output terminals can be in a very high impedance state so that they are easily subjected to electrostatic induction from AC fields of the surrounding space or from charged objects in their vicinity. For this reason, MOS IC/LSIs should be protected from electrostatic charges while being transported and stored by conductive rubber foam, aluminum foil, shielded boxes or other protective precautions.

3. KEEPING ELECTRICAL EQUIPMENT, WORK TABLES AND OPERATING PERSONNEL AT THE SAME POTENTIAL

1. All electric equipment, work table surfaces and operat-

ing personnel should be grounded. Work tables should be covered with copper or aluminum plates of good conductivity, and grounded. One method of grounding personnel, after making sure that there is no potential difference with electrical equipment, is by the use of a wristwatch metallic ring, etc. attached around the wrist and grounded in series with a 1M Ω resistor. Be sure that the grounding meets national regulations on personnel safety.

2. Current leakage from electric equipment must be prevented not only for personnel safety, but also to avert the destruction of MOS IC/LSIs, as described above. Items such as testers, curve-tracers and synchroscopes must be checked for current leakage before being grounded.

4. PRECAUTIONS FOR MOUNTING OF MOS IC/LSIs

1. The printed wiring lines to input and output terminals of MOS IC/LSIs should not be close to or parallel to high-voltage or high-power signal lines. Turning power on while the device is short-circuited, either by a solder bridge made during assembly or by a probe during adjusting and testing, may cause maximum ratings to be exceeded, which may result in the destruction of the device.
2. When input/output, or input and/or output, terminals of MOS IC/LSIs (now open-circuits) are connected, we must consider the possibility of current leakage and take precautions similar to §2 above. To reduce such undesirable trouble, it is recommended that an interface circuit be inserted at the input or output terminal, or a resistor with a resistance that does not exceed the output driving capability of the MOS IC/LSI be inserted between the power supply and the ground.
3. A filter circuit should be inserted in the AC power supply line to absorb surges which can frequently be strong enough to destroy a MOS IC/LSI.
4. Terminal connections should be made as described in the catalog while being careful to meet specifications.
5. Ungrounded metal plates should not be placed near input or output terminals of any MOS IC/LSIs, since destruction of the insulation may result if they become electrostatically charged.
6. Equipment cases should provide shielding from electrostatic charges for more reliable operation. When a plastic case is used, it is desirable to coat the inside of the case with conductive paint and to ground it. This is considered necessary even for battery-operated equipment.

RANDOM-ACCESS MEMORIES

2

16 384-BIT (2048-WORD BY 8-BIT) STATIC RAM

DESCRIPTION

This is a family of 2048-word by 8-bit static RAMs, fabricated with the N-channel silicon-gate MOS process and designed for simple interfacing. These devices operate on a single 5V supply, as does TTL, and are directly TTL-compatible.

The input and output terminals are common, and an \overline{OE} terminal is provided. \overline{S} controls the power-down feature.

FEATURES

- Fast access time:
 - M58725P 200ns (max)
 - M58725 P-15 150ns (max)
- Low power dissipation:
 - Active: 250mW (typ)
 - Stand by: 25mW (typ)
- Power down by \overline{S}
- Single 5V supply voltage ($\pm 10\%$ tolerance)
- Requires neither external clock nor refreshing
- All inputs and outputs are directly TTL compatible
- All outputs are three-state, with OR-tie capability
- Easy memory expansion by chip-select (\overline{S}) input
- Common data DQ terminals.
- Same pin configuration as M5L2716K 16 384-bit EPROM

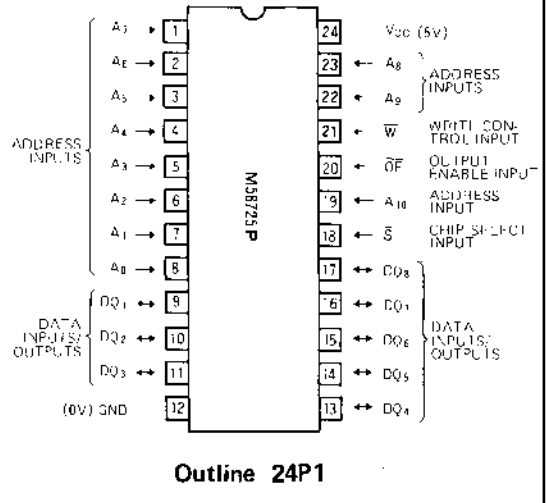

APPLICATION

- Small-capacity memory units

FUNCTION

These devices provide common data input and output terminals. During a write cycle, when a location is designated by address signals $A_0 \sim A_{10}$ the \overline{OE} signal is kept high to keep the DQ terminals in the input mode, signal \overline{W} goes low, and the data of the DQ signal at that time is written.

PIN CONFIGURATION (TOP VIEW)

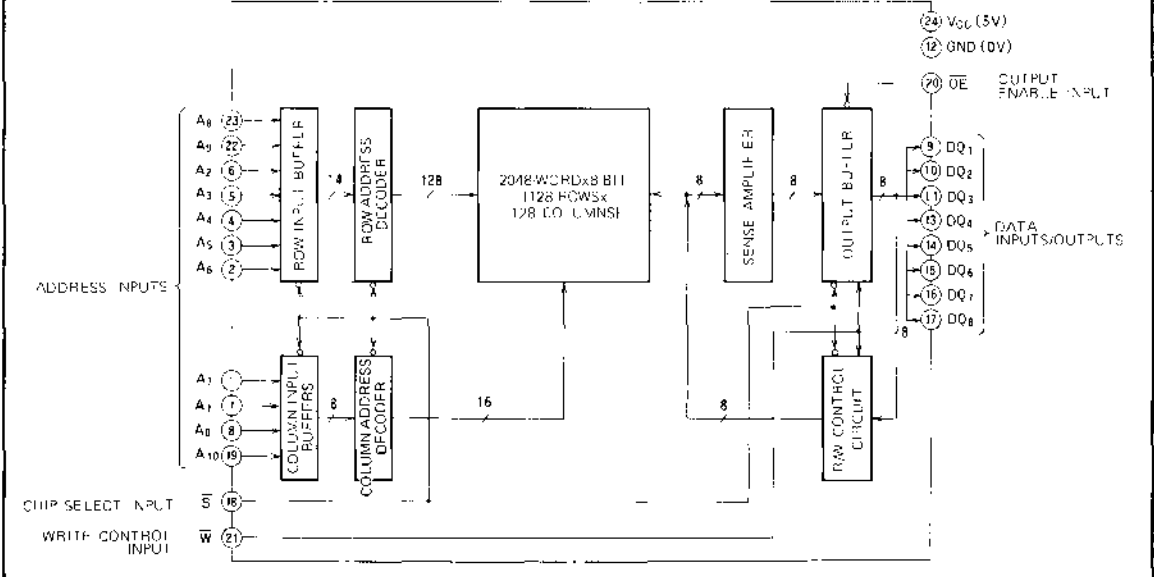

2

During a read cycle, when a location is designated by address signals $A_0 \sim A_{10}$ the \overline{OE} signal is kept low to keep the DQ terminals in the output mode, signal \overline{W} goes high, and the data of the designated address is available at the I/O terminals.

When signal \overline{S} is high, the chip is in the non-selectable state, disabling both reading and writing. In this case the output is in the floating (high-impedance) state, useful for OR-ties with other output terminals.

Signal \overline{S} controls the power down feature. When \overline{S} goes high power dissipation is reduced to 1/10 of active power. The access time from \overline{S} is equivalent to the address access time.

4096-BIT (1024-WORD BY 4-BIT) CMOS STATIC RAM

DESCRIPTION

This is a 1024-word by 4-bit static RAM fabricated with the silicon-gate CMOS process and designed for low power dissipation and easy application of battery back-up.

While maintained in the chip non-select state by the chip-select signal \overline{CS} , it consumes power only at the low value of $15\mu A$ (max) standby current and accordingly is especially suitable as a memory system for battery-operated applications and for battery back-up.

It operates on a single 5V supply, as does TTL, and inputs and outputs are directly TTL-compatible and are provided with common I/O terminals.

FEATURES

- Access time: M58981P-30: 300 ns (max)
 M58981P-45: 450 ns (max)
- Low power dissipation in the standby mode: $15\mu A$ (max)
- Single 5V power supply
- Data holding at 2V supply voltage
- No external clock or refreshing operation required
- Both inputs and outputs are directly TTL-compatible
- Outputs are three-state, with OR-tie capability
- Simple memory expansion by chip-select signal
- Data terminals are common for both inputs and outputs
- Pin configuration is identical with that of Mitsubishi's M5L 2114LP N-channel 4K static RAM, Intel's 2114, and TI's TMS4045

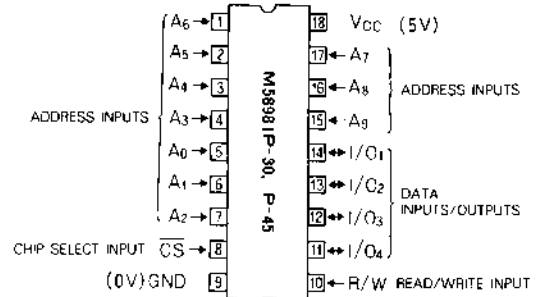

APPLICATION

- Battery-driven or battery back-up small-capacity memory units

FUNCTION

This device provides common data input and output terminals.

PIN CONFIGURATION (TOP VIEW)

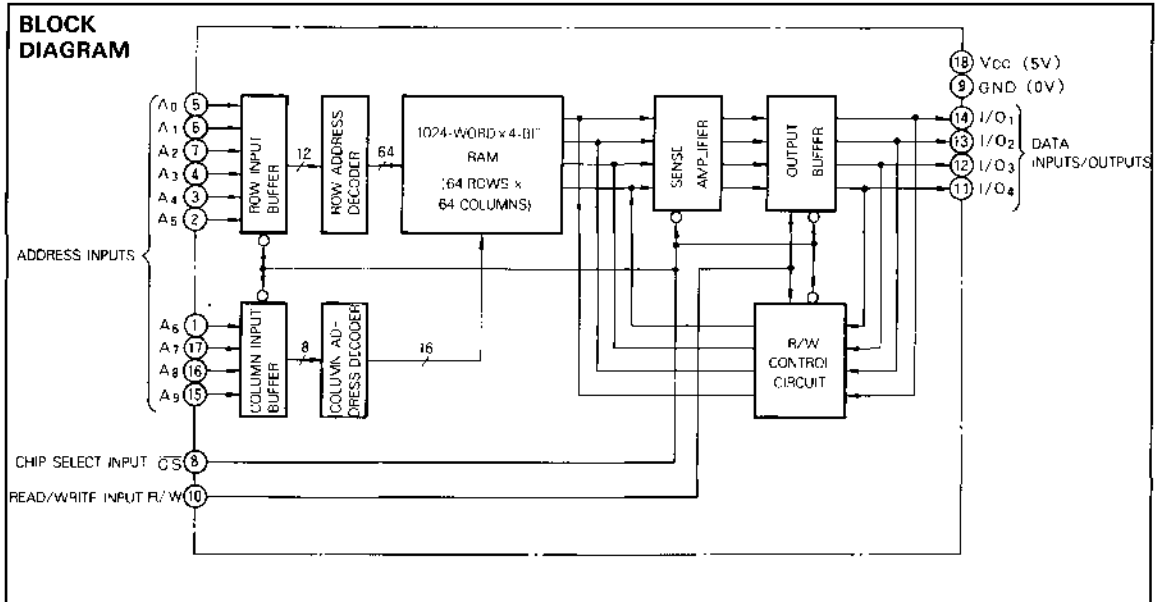

Outline 18P4

During a write cycle, when a location is designated by address signals $A_0 \sim A_9$ and signal R/W goes low, the data of the I/O at that time is written.

During a read cycle, when a location is designated by address signals $A_0 \sim A_9$, and signal R/W goes high, the data of the designated address is available at the I/O terminals.

When signal \overline{CS} is high, the chip is in the non-selectable state, disabling both reading and writing. In this case, the output is in the floating (high-impedance state) useful for OR-ties with the output terminals of other chips.

Also in the chip non-select state, the device operates with a low power dissipation, having a standby current of $15\mu A$ (max), so that the memory data can be held at a supply voltage of 2V, enabling battery back-up operation during power failure and power-down operation in the standby mode.

16 384-BIT (16 384-WORD BY 1-BIT) DYNAMIC RAM

DESCRIPTION

This is a family of 16 384-word by 1-bit dynamic RAMs, fabricated with the N-channel silicon-gate MOS process, and is ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer poly-silicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities.

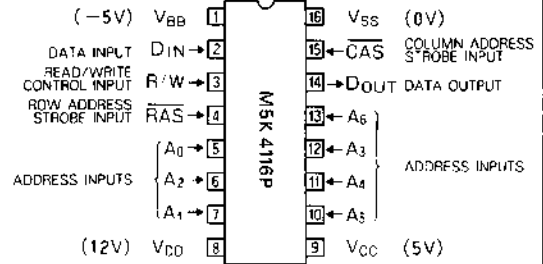

FEATURES

- Performance ranges

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K 4116 P-2	150	320	330
M5K 4116 P-3	200	375	280

- Standard 16-pin package
- Voltage range on all power supplies (V_{DD} , V_{CC} , V_{BB}): $\pm 10\%$
- Low standby power dissipation: 19.8mW (max)
- Low operating power dissipation: 462mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary
- Early-write operation gives common I/O capability
- Read-modify-write, \overline{RAS} -only refresh, and page-mode capabilities
- All input terminals have low input capacitance and are directly TTL-compatible
- Output is three-state and directly TTL-compatible
- 128 refresh cycles

PIN CONFIGURATION (TOP VIEW)

Outline 16P1

- Interchangeable with Mostek's MK4116 in both electrical characteristics and pin configuration

APPLICATION

- Main memory unit for computers

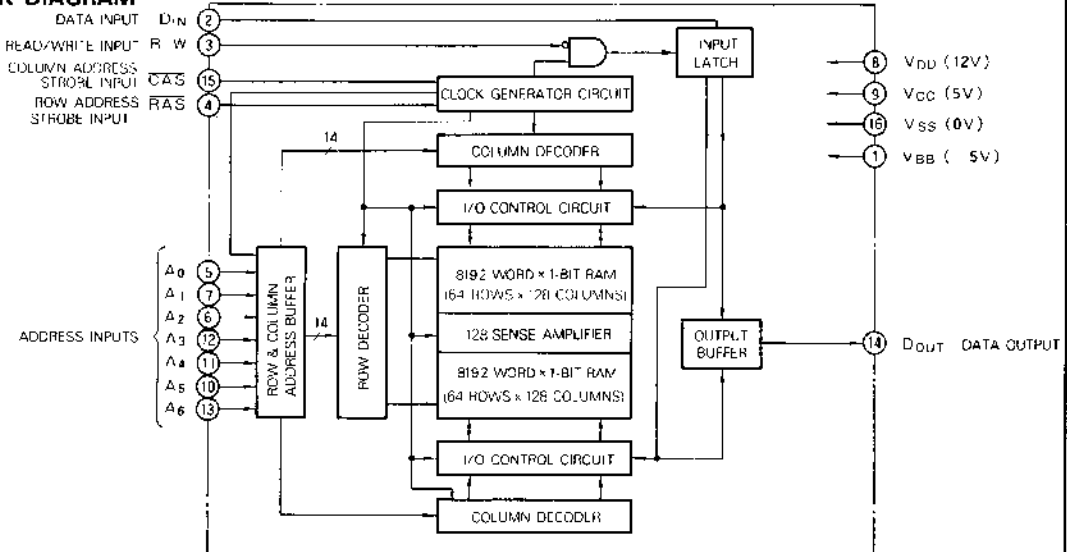

FUNCTION

The M5K4116P provide, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, \overline{RAS} -only refresh, and delayed-write. The input conditions for each are shown below.

Operation	Inputs						Output	Re-fresh	Remarks
	\overline{RAS}	\overline{CAS}	R/W	DIN	How address	Column address			
Read	ACT	ACT	NAC	DNC	APD	APD	VLD	YES	Page mode identical except refresh is NO
Write	ACT	ACT	ACT	VLD	APD	APD	OPN	YES	
Read modify write	ACT	ACT	ACT	VLD	APD	APD	VLD	YES	
\overline{RAS} -only refresh	ACT	NAC	DNC	DNC	APD	DNC	OPN	YES	
Standby	NAC	DNC	DNC	DNC	DNC	DNC	OPN	NO	

Note ACT: active, NAC: nonactive, DNC: don't care, VLD: valid, APD: applied, OPN: open

BLOCK DIAGRAM

16 384-BIT (16 384-WORD BY 1-BIT) DYNAMIC RAM

SUMMARY OF OPERATIONS

Addressing

To select one of the 16 384 memory cells in the M5K 4116 P the 14-bit address signal must be multiplexed into 7 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse (\overline{RAS}) latches the 7 row-address bits; next, the negative-going edge of the column-address-strobe pulse (\overline{CAS}) latches the 7 column-address bits. Timing of the \overline{RAS} and \overline{CAS} clocks can be selected by either of the following two methods:

1. The delay time from \overline{RAS} to \overline{CAS} $t_{d(\overline{RAS}-\overline{CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal \overline{CAS} control signals are inhibited almost until $t_{d(\overline{RAS}-\overline{CAS})\max}$ ('gated \overline{CAS} ' operation). The external \overline{CAS} signal can be applied with a margin not affecting the on-chip circuit operations, e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\overline{RAS}-\overline{CAS})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of \overline{CAS} has already been released, so that the internal \overline{CAS} control signals are controlled by the externally applied \overline{CAS} , which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of R/W input and \overline{CAS} input. Thus when the R/W input makes its negative transition prior to \overline{CAS} input (early write), the data input is strobed by \overline{CAS} , and the negative transition of \overline{CAS} is set as the reference point for set-up and hold times. In the read-write or read-modify-write cycles, however, when the R/W input makes its negative transition after \overline{CAS} , the R/W negative transition is set as the reference point for set-up and hold times.

Data Output Control

The output of the M5K 4116P is in the high-impedance state when \overline{CAS} is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until \overline{CAS} goes high, irrespective of the condition of \overline{RAS} (for a maximum of 10 μ s).

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K 4116P which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the \overline{CAS}

pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time, until the next cycle commences. This enables extremely flexible clock-timing settings for \overline{RAS} and \overline{CAS} .

3. Two Methods of Chip Selection

Since the output is not latched, \overline{CAS} is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that \overline{CAS} and/or \overline{RAS} can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding \overline{CAS} , the page boundary can be extended beyond the 128 column locations in a single chip. In this case, \overline{RAS} must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of \overline{RAS} , because once the row address has been strobed, \overline{RAS} is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

The refreshing of the dynamic cell matrix is accomplished by performing a memory operation at each of the 128 row-address locations within a 2ms time interval. Any normal memory cycle will perform the refreshing, and \overline{RAS} -only refresh offers a significant reduction in operating power.

Power Dissipation

Most of the circuitry in the M5K 4116P is dynamic, and most of the power is dissipated when addresses are strobed. Both \overline{RAS} and \overline{CAS} are decoded and applied to the M5K 4116P as chip-select in the memory system, but if \overline{RAS} is decoded, all unselected devices go into stand-by independent of the \overline{CAS} condition, minimizing system power dissipation.

Power Supplies

Although the M5K 4116P require no particular power-supply sequencing so long as the devices are used within the limits of the absolute maximum ratings, it is recommended that the V_{BB} supply be applied first and removed last. V_{BB} should never be more positive than V_{SS} when power supply is applied to V_{DD} .

Some eight dummy cycles are necessary after power is applied to the device before memory operation is achieved.

16 384-BIT (16 384-WORD BY 1-BIT) DYNAMIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{DD}	Supply voltage	With respect to	0.5 ~ 20	V
V _{CC}	Supply voltage		-0.5 ~ 20	V
V _{SS}	Supply voltage		-0.5 ~ 20	V
V _I	Input voltage		-0.5 ~ 20	V
V _O	Output voltage		-0.5 ~ 20	V
V _{DD}	Supply voltage	With respect to V _{SS}	1 ~ 15	V
V _{CC}	Supply voltage		-1 ~ 15	V
V _{BB} - V _{SS}	Supply voltage		V _{CC} - V _{SS} > 0	0
I _O	Output current		50	mA
P _d	Power dissipation	T _a = 25 °C	700	mW
T _{OP}	Operating free-air temperature range		0 ~ 70	°C
T _{stg}	Storage temperature range		-65 ~ 150	°C

2

RECOMMENDED OPERATING CONDITIONS (T_a = 0 ~ 70 °C, unless otherwise noted. Note 3)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V _{DD}	Supply voltage	10.8	12	13.2	V
V _{CC}	Supply voltage (Note 2)	4.5	5	5.5	V
V _{SS}	Supply voltage	0	0	0	V
V _{BB}	Supply voltage	-4.5	-5	-5.7	V
V _{IH1}	High-level input voltage, RAS, CAS, H W	2.7		7	V
V _{IH2}	High-level input voltage, A ₀ - A ₆ , D _{IN}	2.4		7	V
V _{IL}	Low-level input voltage, all inputs	1		0.8	V

- Note 1: All voltages with respect to V_{SS}. Apply V_{BB} power supply first, prior to other power supplies, and remove last.
 Note 2: The output voltage will swing from V_{SS} to V_{CC} when output loading current is zero. In standby mode V_{CC} may be reduced to V_{SS} without affecting refresh operations or data retention, but the V_{OH,min} specification is not guaranteed in this mode.

ELECTRICAL CHARACTERISTICS

(T_a = 0 ~ 70 °C, V_{DD} = 12V ± 10%, V_{CC} = 5V ± 10%, V_{SS} = 0V, -5.7V < V_{BB} < -4.5V, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
V _{OH}	High-level output voltage (Note 2)	I _{OH} = -5 mA	2.4		V _{CC}	V
V _{OL}	Low-level output voltage (Note 2)	I _{OL} = 4.2 mA	0		0.4	V
I _{OZ}	Off-state output current	D _{OUT} floating 0V ≤ V _{OH} ≤ 5.5V	10		10	μA
I _I	Input current	V _{DR} = 5V, 0V ≤ V _{IN} ≤ 7V All other pins = 0V	-10		10	μA
I _{DD1(AV)}	Average supply current from V _{DD} , operating	RAS, CAS cycling t _{0(RD)} = t _{0(WR)} = min			35	mA
I _{CC1(AV)}	Average supply current from V _{CC} , operating (Note 4)					
I _{BB1(AV)}	Average supply current from V _{BB} , operating				200	μA
I _{DD2}	Supply current from V _{DD} , standby	RAS = V _{IH} D _{OUT} = floating			1.5	mA
I _{CC2}	Supply current from V _{CC} , standby		-10		10	μA
I _{BB2}	Supply current from V _{BB} , standby				100	μA
I _{DD3(AV)}	Average supply current from V _{DD} , refreshing	RAS cycling, CAS = V _{IH} t _{0(REF)} = min			27	mA
I _{CC3(AV)}	Average supply current from V _{CC} , refreshing		-10		10	μA
I _{BB3(AV)}	Average supply current from V _{BB} , refreshing				200	μA
I _{DD4(AV)}	Average supply current from V _{DD} , page mode	RAS, V _{IL} , CAS t _{0(PG)} = min			27	mA
I _{CC4(AV)}	Average supply current from V _{CC} , page mode (Note 4)					
I _{BB4(AV)}	Average supply current from V _{BB} , page mode				200	μA
C _{I(A0)}	Input capacitance, address inputs				5	pF
C _{I(DA)}	Input capacitance, data input	V _I = V _{SS}			5	pF
C _{I(H W)}	Input capacitance, read/write control input	f = 1MHz			7	pF
C _{I(RAS)}	Input capacitance, RAS input	V _I = 25mVrms			10	pF
C _{I(CAS)}	Input capacitance, CAS input				10	pF
C _O	Output capacitance	V _O = V _{SS} , f = 1MHz, V _I = 25mVrms			7	pF

- Note 3: Except for I_{BB}, current flowing into an iC is positive; out is negative.
 Note 4: V_{CC} is connected only to the output buffer, so that I_{CC1} and I_{CC4} depend upon output loading.

16 384-BIT (16 384-WORD BY 1-BIT) DYNAMIC RAM

TIMING REQUIREMENTS (For Read, Write, Read-Modify-Write, Refresh, and Page-Mode Cycles)

($T_a = 0 - 70^\circ\text{C}$, $V_{DD} = 12\text{V} \pm 10\%$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, $-5.7\text{V} \leq V_{BB} \leq -4.5\text{V}$, unless otherwise noted. See notes 5, 6, and 7.)

Symbol	Parameter	Alternative Symbol	M5K4116P-2		M5K4116P-3		Unit
			Limits		Limits		
			Min	Max	Min	Max	
$t_{c(\text{REF})}$	Refresh cycle time	t_{REF}		2		2	ns
$t_{w(\text{RAS})}$	RAS high pulse width	t_{RP}	100		120		ns
$t_{w(\text{RAS})}$	RAS low pulse width	t_{RAS}	150	10000	200	10000	ns
$t_{w(\text{CAS})}$	CAS low pulse width (Note 8)	t_{CAS}	100	10000	135	10000	ns
$t_{h(\text{RAS-CAS})}$	CAS hold time with respect to RAS	t_{CSH}	150		200		ns
$t_{h(\text{CAS-RAS})}$	RAS hold time with respect to CAS	t_{RSH}	100		135		ns
$t_{d(\text{RAS-CAS})}$	Delay time, RAS to CAS (Note 9)	t_{RCD}	20	50	25	65	ns
$t_{d(\text{CAS-RAS})}$	Delay time, CAS to RAS	t_{CRP}	-20		-20		ns
$t_{su(\text{RA-RAS})}$	Row address setup time with respect to RAS	t_{ASR}	0		0		ns
$t_{su(\text{CA-CAS})}$	Column address setup time with respect to CAS	t_{ASC}	-10		-10		ns
$t_{h(\text{RAS-RA})}$	Row address hold time with respect to RAS	t_{RAH}	20		25		ns
$t_{h(\text{CAS-CA})}$	Column address hold time with respect to CAS	t_{CAH}	45		55		ns
$t_{h(\text{RAS-CA})}$	Column address hold time with respect to RAS	t_{AR}	95		120		ns
t_{THL} t_{TLH}	Transition time	t_{T}	3	35	3	50	ns

Note 5 After power supply is applied, some eight dummy cycles are required before memory operation is achieved. RAS/CAS refresh cycles or RAS read-only cycles are suitable as dummy cycles. Once power is applied, it is also recommended to keep the RAS at high-level for more than 3 μ s before the dummy cycles, or to keep the RAS high pulse width $t_{w(\text{RAS})}$ more than 3 μ s for a minimum of one dummy cycle.

6 The switching characteristics are defined as $t_{\text{THL}} = t_{\text{TLH}} = 50\text{ns}$.

7 Reference levels of input signals are V_{IH1} min, V_{IH2} min and V_{IL} max. Reference levels for transition time are also between V_{H1} or V_{H2} and V_{L} .

8 Assumes that $t_{d(\text{RAS-CAS})} \geq t_{d(\text{RAS-CAS})\text{max}}$. If $t_{d(\text{RAS-CAS})} < t_{d(\text{RAS-CAS})\text{max}}$, $t_{w(\text{CAS})}$ will be increased by the amount that $t_{d(\text{RAS-CAS})}$ has decreased.

9 The maximum value of $t_{d(\text{RAS-CAS})}$ does not define the limit of operation, but is specified as a reference point only if $t_{d(\text{RAS-CAS})}$ is greater than the specified $t_{d(\text{RAS-CAS})\text{max}}$ limit, then access time is controlled exclusively by $t_{d(\text{CAS})}$.

SWITCHING CHARACTERISTICS ($T_a = 0 - 70^\circ\text{C}$, $V_{DD} = 12\text{V} \pm 10\%$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, $-5.7\text{V} \leq V_{BB} \leq -4.5\text{V}$, unless otherwise noted)

$t_{su(DA-WR)}$	Data-in set-up time with respect to write	t_{DS}	0		0		ns
$t_{r(WR-DA)}$	Data-in hold time with respect to write	t_{DH}	45		55		ns
$t_{h(\overline{CAS}-OUT)}$	Data-out hold time with respect to \overline{CAS}	t_{OFF}	0	40	0	50	ns
$t_a(\overline{CAS})$	\overline{CAS} access time (Note 10)	t_{CAG}		100		135	ns
$t_a(\overline{RAS})$	\overline{RAS} access time (Note 11)	t_{RAG}		150		200	ns

Note 12 : $t_{su(WR-\overline{CAS})}$, $t_{d(\overline{RAS}-WR)}$, and $t_{d(\overline{CAS}-WR)}$ do not define the limits of operation, but are included as electrical characteristics only.
 When $t_{su(WR-\overline{CAS})} \geq t_{su(WR-\overline{CAS})\min}$, an early-write cycle is performed, and the data output keeps the high-impedance state.
 When $t_{d(\overline{RAS}-WR)} \geq t_{d(\overline{RAS}-WR)\min}$ and $t_{d(\overline{CAS}-WR)} \geq t_{d(\overline{CAS}-WR)\min}$, a read-modify-write cycle is performed, and the data of the selected address will be read out on the data outputs.
 For all conditions other than those described above the condition of data output is not defined.

MITSUBISHI LSIs

M5K4164P-15, P-20

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

DESCRIPTION

This is a family of 65 536-word by 1-bit dynamic RAMs, fabricated with the high performance N-channel silicon-gate MOS process, and is ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer polysilicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities. The M5K4164P operates on a 5V power supply using the on-chip substrate bias generator.

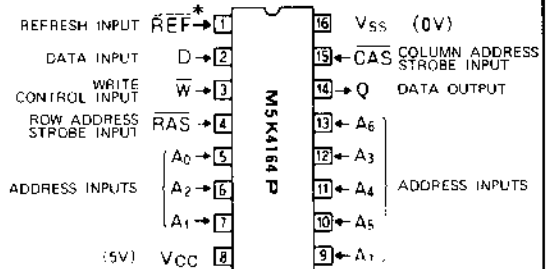

FEATURES

- Performance ranges

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K4164P-15	150	260	200
M5K4164P-20	200	330	170

- Standard 16-pin package
- Single 5V $\pm 10\%$ supply
- Low standby power dissipation: 22mW (max)
- Low operating power dissipation:
 - M5K4164P-15 275mW (max)
 - M5K4164P-20 250mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary
- Early-write operation gives common I/O capability
- Read-modify-write, $\overline{\text{RAS}}$ -only refresh, and page-mode capabilities

PIN CONFIGURATION (TOP VIEW)

* If the pin 1 ($\overline{\text{REF}}$) function is not used, pin 1 may be left open (not connect).

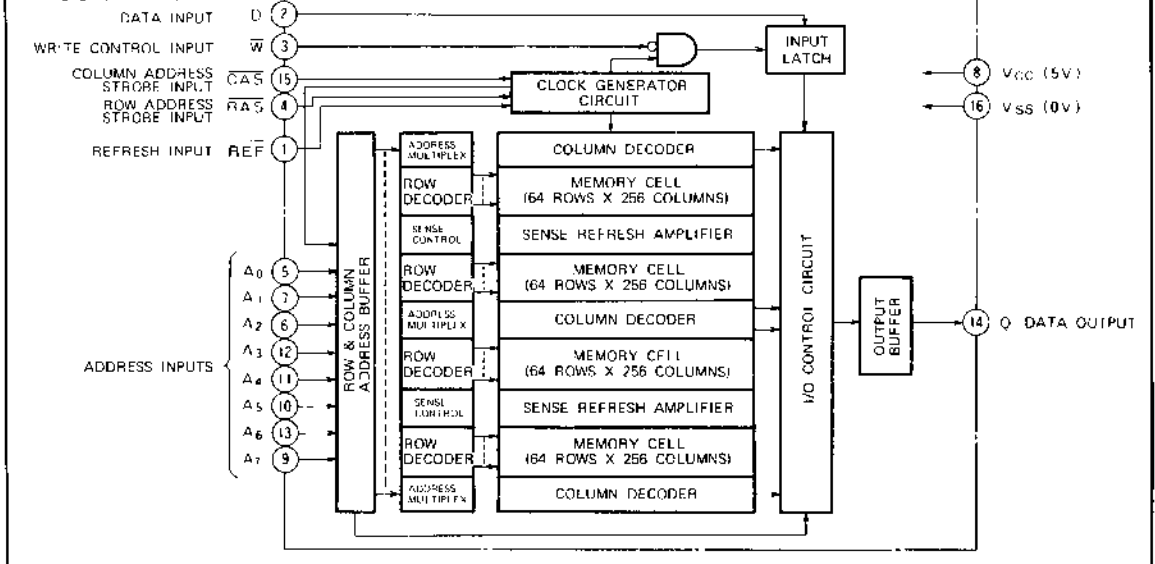

Outline 16P4

- All input terminals have low input capacitance and are directly TTL-compatible
- Output is three-state and directly TTL-compatible
- 128 refresh cycles every 2ms (16K dynamic RAMs M5K4116P, S compatible)
- Pin 1 controls automatic- and self-refresh mode
- $\overline{\text{CAS}}$ controlled output allows hidden refresh, hidden automatic refresh and hidden self-refresh
- Output data can be held infinitely by $\overline{\text{CAS}}$
- Interchangeable with Mostek's MK4164 and Motorola's MCM 6664 in pin configuration

APPLICATION

- Main memory unit for computers

BLOCK DIAGRAM

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

FUNCTION

The M5K4164P provides, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, $\overline{\text{RAS}}$ -only refresh, and delayed-write. The input conditions for each are shown in Table 1.

Table 1 Input conditions for each mode

Operation	Inputs							Output		Refresh	Remarks
	$\overline{\text{RAS}}$	$\overline{\text{CAS}}$	$\overline{\text{W}}$	D	Row address	Column address	$\overline{\text{REF}}$	Q			
Read	ACT	ACT	NAC	DNC	APD	APD	NAC	VLD	YES	Page mode identical except refresh is NO.	
Write	ACT	ACT	ACT	VLD	APD	APD	NAC	OPN	YES		
Read-modify-write	ACT	ACT	ACT	VLD	APD	APD	NAC	VLD	YES		
$\overline{\text{RAS}}$ -only refresh	ACT	NAC	DNC	DNC	APD	DNC	NAC	OPN	YES		
Hidden refresh	ACT	ACT	DNC	DNC	APD	DNC	NAC	VLD	YES		
Automatic refresh	NAC	DNC	DNC	DNC	DNC	DNC	ACT	OPN	YES		
Self refresh	NAC	DNC	DNC	DNC	DNC	DNC	ACT	OPN	YES		
Hidden automatic refresh	NAC	ACT	DNC	DNC	DNC	DNC	ACT	VLD	YES		
Hidden self refresh	NAC	ACT	DNC	DNC	DNC	DNC	ACT	VLD	YES		
Standby	NAC	DNC	DNC	DNC	DNC	DNC	NAC	OPN	NO		

Note ACT : active, NAC : nonactive, DNC : don't care, VLD : valid, APD : applied, OPN : open

SUMMARY OF OPERATIONS

Addressing

To select one of the 65 536 memory cells in the M5K4164P the 16-bit address signal must be multiplexed into 8 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{\text{RAS}}$) latches the 8 row-address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{\text{CAS}}$) latches the 8 column-address bits. Timing of the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ clocks can be selected by either of the following two methods:

1. The delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ $t_{d(\overline{\text{RAS}}-\overline{\text{CAS}})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{\text{CAS}}$ control signals are inhibited almost until $t_{d(\overline{\text{RAS}}-\overline{\text{CAS}})_{\text{max}}}$ ('gated $\overline{\text{CAS}}$ ' operation). The external $\overline{\text{CAS}}$ signal can be applied with a margin not affecting the on-chip circuit operations, e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\overline{\text{RAS}}-\overline{\text{CAS}})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of $\overline{\text{CAS}}$ has already been released, so that the internal $\overline{\text{CAS}}$ control signals are controlled by the externally applied $\overline{\text{CAS}}$, which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of $\overline{\text{W}}$ input and $\overline{\text{CAS}}$ input. Thus when the $\overline{\text{W}}$ input makes its negative transition prior to $\overline{\text{CAS}}$ input (early write), the data input is strobed by $\overline{\text{CAS}}$, and the negative transition of $\overline{\text{CAS}}$ is set as the reference point for set-up and hold times. In the read-write

or read-modify-write cycles, however, when the $\overline{\text{W}}$ input makes its negative transition after $\overline{\text{CAS}}$, the $\overline{\text{W}}$ negative transition is set as the reference point for setup and hold times.

Data Output Control

The output of the M5K4164P is in the high-impedance state when $\overline{\text{CAS}}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until $\overline{\text{CAS}}$ goes high, irrespective of the condition of $\overline{\text{RAS}}$.

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K4164P, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{\text{CAS}}$ pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time. This enables extremely flexible clock-timing settings for $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

2

3. Two Methods of Chip Selection

Since the output is not latched, $\overline{\text{CAS}}$ is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that $\overline{\text{CAS}}$ and/or $\overline{\text{RAS}}$ can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding $\overline{\text{CAS}}$, the page boundary can be extended beyond the 256 column locations in a single chip. In this case, $\overline{\text{RAS}}$ must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of $\overline{\text{RAS}}$, because once the row address has been strobed, $\overline{\text{RAS}}$ is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

Each of the 128 rows ($A_0 \sim A_6$) of the M5K4164P must be refreshed every 2 ms to maintain data. The methods of refreshing for the M5K4164P are as follows.

1. Normal Refresh

Read cycle and Write cycle (early write, delayed write or read-modify-write) refresh the selected row as defined by the low order ($\overline{\text{RAS}}$) addresses. Any write cycle, of course, may change the state of the selected cell. Using a read, write, or read-modify-write cycle for refresh is not recommended for systems which utilize "wire-OR" outputs since output bus contention will occur.

2. $\overline{\text{RAS}}$ Only Refresh

A $\overline{\text{RAS}}$ -only refresh cycle is the recommended technique for most applications to provide for data retention. A $\overline{\text{RAS}}$ -only refresh cycle maintains the output in the high-impedance state with a typical power reduction of 20% over a read or write cycle.

3. Automatic Refresh

Pin 1 ($\overline{\text{REF}}$) has two special functions. The M5K4164P has a refresh address counter, refresh address multiplexer and refresh timer for these operations. Automatic refresh is initiated by bringing $\overline{\text{REF}}$ low after $\overline{\text{RAS}}$ has precharged and is used during standard operation just like $\overline{\text{RAS}}$ -only refresh, except that sequential row addresses from an external counter are no longer necessary.

At the end of automatic refresh cycle, the internal refresh address counter will be automatically incremented. The output state of the refresh address counter is initiated by some eight $\overline{\text{REF}}$, $\overline{\text{RAS}}$ or $\overline{\text{RAS/CAS}}$ cycle after power is applied. Therefore, a special operation is not necessary to initiate it.

$\overline{\text{RAS}}$ must remain inactive during $\overline{\text{REF}}$ activated cycles. Likewise, $\overline{\text{REF}}$ must remain inactive during $\overline{\text{RAS}}$ generated cycle.

4. Self-Refresh

The other function of pin 1 ($\overline{\text{REF}}$) is self-refresh. Timing for self-refresh is quite similar to that for automatic refresh. As long as $\overline{\text{RAS}}$ remains high and $\overline{\text{REF}}$ remains low, the M5K4164P will refresh itself. This internal sequence repeats asynchronously every 12 to 16 μs . After 2 ms, the on-chip refresh address counter has advanced through all the row addresses and refreshed the entire memory. Self-refresh is primarily intended for trouble free power-down operation.

For example, when battery backup is used to maintained data integrity in the memory, $\overline{\text{REF}}$ may be used to place the device in the self-refresh mode with no external timing signals necessary to keep the information alive.

In summary, the pin 1 ($\overline{\text{REF}}$) refresh function gives the user a feature that is free, save him hardware on the board, and in fact, will simplify his battery backup procedures, increase his battery life, and save him overall cost while giving him improved system performance.

There is an internal pullup resistor ($\approx 3M\Omega$) on pin 1, so if the pin 1 ($\overline{\text{REF}}$) function is not used, pin 1 may be left open (not connect) without affecting the normal operations.

5. Hidden Refresh

A features of the M5K4164P is that refresh cycle may be performed while maintaining valid data at the output pin by extending the $\overline{\text{CAS}}$ active time from a previous memory read cycle. This feature is referred to as hidden refresh.

Hidden refresh is performed by holding $\overline{\text{CAS}}$ at V_{IL} and taking $\overline{\text{RAS}}$ high and after a specified precharge period, executing a $\overline{\text{RAS}}$ -only cycling, automatic refresh and self-refresh, but with $\overline{\text{CAS}}$ held low.

The advantage of this refresh mode is that data can be held valid at the output data port indefinitely by leaving the $\overline{\text{CAS}}$ asserted. In many applications this eliminates the need for off-chip latches.

Power Dissipation

Most of the circuitry in the M5K4164P is dynamic, and most of the power is dissipated when addresses are strobed. Both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ are decoded and applied to the M5K4164P as chip-select in the memory system, but if $\overline{\text{RAS}}$ is decoded, all unselected devices go into stand-by independent of the $\overline{\text{CAS}}$ condition, minimizing system power dissipation.

Power Supplies

The M5K4164P operates on a single 5V power supply.

A wait of some 500 μs and eight or more dummy cycle is necessary after power is applied to the device before memory operation is achieved.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage		-1 ~ 7	V
V _I	Input voltage	With respect to V _{SS}	-1 ~ 7	V
V _O	Output voltage		-1 ~ 7	V

C _{I(D)}	Input capacitance, data input	V _I = V _{SS}			5	pF
C _{I(W)}	Input capacitance, write control input	f = 1MHz			7	pF
C _{I(RAS)}	Input capacitance, R _{AS} input	V _I = 25mVrms			10	pF
C _{I(CAS)}	Input capacitance, C _{AS} input				10	pF
C _{I(REF)}	Input capacitance, REF input				10	pF
C _O	Output capacitance	V _O = V _{SS} , f = 1MHz, V _I = 25mVrms			7	pF

Note 2: Current flowing into an IC is positive, out is negative.

- I_{CC1(AV)}, I_{CC3(AV)}, I_{CC4(AV)} and I_{CC5(AV)} are dependent on cyclic rate. Maximum current is measured at the fastest cycle rate.
- I_{CC1(AV)} and I_{CC4(AV)} are dependent on output loading. Specified values are obtained with the output open.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

TIMING REQUIREMENTS (For Read, Write, Read-Modify-Write, Refresh, and Page-Mode Cycle)

($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted. See notes 5, 6 and 7.)

Symbol	Parameter	Alternative Symbol	M5K4164P-15		M5K4164P-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{REF}	Refresh cycle time	t_{REF}	2		2		ms
$t_{\text{W}}(\text{RAS})$	RAS high pulse width	t_{RP}	100		120		ns
$t_{\text{W}}(\text{RASL})$	RAS low pulse width	t_{RAS}	150	10000	200	10000	ns
$t_{\text{W}}(\text{CASL})$	CAS low pulse width	t_{CAS}	75	∞	100	∞	ns
$t_{\text{W}}(\text{CASH})$	CAS high pulse width (Note 8)	t_{CPN}	35		40		ns
$t_{\text{H}}(\text{RAS-CAS})$	CAS hold time after RAS	t_{CSH}	150		200		ns
$t_{\text{H}}(\text{CAS-RAS})$	RAS hold time after CAS	t_{RSH}	75		100		ns
$t_{\text{d}}(\text{CAS-RAS})$	Delay time, CAS to RAS (Note 9)	t_{CRP}	-20		-20		ns
$t_{\text{d}}(\text{RAS-CAS})$	Delay time, RAS to CAS (Note 10)	t_{RCD}	25	75	30	100	ns
$t_{\text{SU}}(\text{RA-RAS})$	Row address setup time before RAS	t_{ASR}	0		0		ns
$t_{\text{SU}}(\text{CA-CAS})$	Column address setup time before CAS	t_{ASC}	-5		-5		ns
$t_{\text{H}}(\text{RAS-RA})$	Row address hold time after RAS	t_{RAH}	20		25		ns
$t_{\text{H}}(\text{CAS-CA})$	Column address hold time after CAS	t_{CAH}	25		35		ns
$t_{\text{H}}(\text{RAS-CA})$	Column address hold time after RAS	t_{AR}	95		120		ns
t_{THL}	Transition time	t_{T}	3	35	3	50	ns

2

- Note 5: An initial pause of 500 μ s is required after power-up followed by any eight REF, RAS or RAS/CAS cycles before proper device operation is achieved.
 Note 6: The switching characteristics are defined as $t_{\text{THL}} = t_{\text{TLH}} - 5\text{ns}$.
 Note 7: Reference levels of input signals are $V_{\text{IH min}}$ and $V_{\text{IL max}}$. Reference levels for transition time are also between V_{IH} and V_{IL} .
 Note 8: Except for page-mode.
 Note 9: $t_{\text{d}}(\text{CAS-RAS})$ requirement is only applicable for RAS/CAS cycles preceded by a CAS or $\overline{\text{CAS}}$ cycle (i.e., for systems where $\overline{\text{CAS}}$ has not been decoded with RAS).
 Note 10: Operation within the $t_{\text{d}}(\text{RAS-CAS})$ max limit insures that $t_{\text{a}}(\text{RAS})$ max can be met. $t_{\text{d}}(\text{RAS-CAS})$ max is specified reference point only; if $t_{\text{d}}(\text{RAS-CAS})$ is greater than the specified $t_{\text{d}}(\text{RAS-CAS})$ max limit, then access time is controlled exclusively by $t_{\text{a}}(\text{CAS})$.
 $t_{\text{d}}(\text{RAS-CAS})_{\text{min}} = t_{\text{H}}(\text{RAS-RA})_{\text{min}} + 2t_{\text{THL}}(t_{\text{TLH}}) + t_{\text{SU}}(\text{CA-CAS})_{\text{min}}$.

SWITCHING CHARACTERISTICS ($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted.)

Read Cycle

Symbol	Parameter	Alternative Symbol	M5K4164P-15		M5K4164P-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{CR}	Read cycle time	t_{RC}	260		330		ns
$t_{\text{SU}}(\text{R-CAS})$	Read setup time before CAS	t_{RCS}	0		0		ns
$t_{\text{H}}(\text{CAS-R})$	Read hold time after CAS (Note 11)	t_{RCH}	0		0		ns
$t_{\text{H}}(\text{RAS-R})$	Read hold time after RAS (Note 11)	t_{RRH}	20		25		ns
$t_{\text{DIS}}(\text{CAS})$	Output disable time (Note 12)	t_{OFF}	0	40	0	50	ns
$t_{\text{a}}(\text{CAS})$	CAS access time (Note 13)	t_{CAC}		75		100	ns
$t_{\text{a}}(\text{RAS})$	RAS access time (Note 14)	t_{RAC}		150		200	ns

- Note 11: Either $t_{\text{H}}(\text{RAS-R})$ or $t_{\text{H}}(\text{CAS-R})$ must be satisfied for a read cycle.
 Note 12: $t_{\text{DIS}}(\text{CAS})_{\text{max}}$ defines the time at which the output achieves the open circuit condition and is not reference to V_{OH} or V_{OL} .
 Note 13: This is the value when $t_{\text{d}}(\text{RAS-CAS}) \geq t_{\text{d}}(\text{RAS-CAS})_{\text{max}}$. Test conditions: Load = 2TTL, $C_L = 100\text{pF}$.
 Note 14: This is the value when $t_{\text{d}}(\text{RAS-CAS}) < t_{\text{d}}(\text{RAS-CAS})_{\text{max}}$. When $t_{\text{d}}(\text{RAS-CAS}) \geq t_{\text{d}}(\text{RAS-CAS})_{\text{max}}$, $t_{\text{a}}(\text{RAS})$ will increase by the amount that $t_{\text{d}}(\text{RAS-CAS})$ exceeds the value shown. Test conditions: Load = 2TTL, $C_L = 100\text{pF}$.

Write Cycle

Read-Write and Read-Modify-Write Cycles

Symbol	Parameter	Alternative Symbol	MSK4164P-15		MSK4164P-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t _{ORW}	Read-write cycle time (Note 15)	t _{RWC}	280		340		ns
t _{ORMW}	Read modify write cycle time (Note 16)	t _{RMWC}	310		390		ns
t _{h(W-RAS)}	RAS hold time after write	t _{RWL}	45		55		ns
t _{h(W-CAS)}	CAS hold time after write	t _{CWL}	45		55		ns
t _{w(W)}	Write pulse width	t _{WP}	45		55		ns
t _{su(R-CAS)}	Read setup time before CAS	t _{RCS}	0		0		ns
t _{d(RAS-W)}	Delay time, RAS to write (Note 17)	t _{RWD}	120		150		ns
t _{d(CAS-W)}	Delay time, CAS to write (Note 17)	t _{CWD}	60		80		ns
t _{su(D-W)}	Data-in setup time before write	t _{DS}	0		0		ns
t _{h(W-D)}	Data-in hold time after write	t _{DH}	45		55		ns
t _{dis(CAS)}	Output disable time	t _{OFF}	0	40	0	50	ns
t _{a(CAS)}	CAS access time (Note 13)	t _{CAC}		75		100	ns
t _{a(RAS)}	RAS access time (Note 14)	t _{RAC}		150		200	ns

Note 15. t_{ORW min} is defined as t_{ORW min} = t_{d(RAS-W)} + t_{h(W-RAS)} + t_{w(RASH)} + 3t_{TLH(tTH)}

16. t_{ORMW min} is defined as t_{ORMW min} = t_{a(RAS)max} + t_{h(W-RAS)} + t_{w(RASH)} + 3t_{TLH(tTH)}

17. t_{su(W-CAS)}, t_{d(RAS-W)}, and t_{d(CAS-W)} do not define the limits of operation, but are included as electrical characteristics only.

When t_{su(W-CAS)} ≥ t_{su(W-CAS)min}, an early-write cycle is performed, and the data output keeps the high-impedance state.

When t_{d(RAS-W)} ≥ t_{d(RAS-W)min}, and t_{d(CAS-W)} ≥ t_{su(W-CAS)min} in a read-write cycle is performed, and the data of the selected address will be read out on the data output.

For all conditions other than those described above, the condition of data output (at access time and until CAS goes back to V_{1H}) is not defined.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

DESCRIPTION

This is a family of 65 536-word by 1-bit dynamic RAMs, fabricated with the high performance N-channel silicongate MOS process, and is ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer polysilicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities. The M5K4164NP operates on a 5V power supply using the on-chip substrate bias generator.

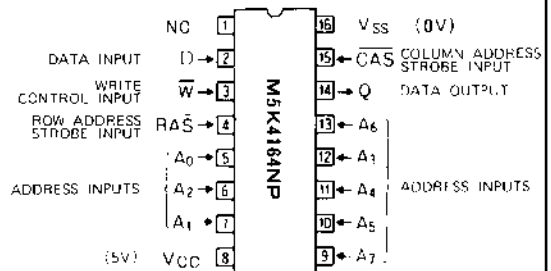

FEATURES

• Performance ranges

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K4164NP-15	150	260	200
M5K4164NP-20	200	330	170

- Standard 16-pin package
- Single 5V±10% supply
- Low standby power dissipation: 22mW (max)
- Low operating power dissipation:
 - M5K4164NP-15 275mW (max)
 - M5K4164NP-20 250mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary
- Early-write operation gives common I/O capability
- Read-modify-write, RAS-only refresh, and page-mode capabilities

PIN CONFIGURATION (TOP VIEW)

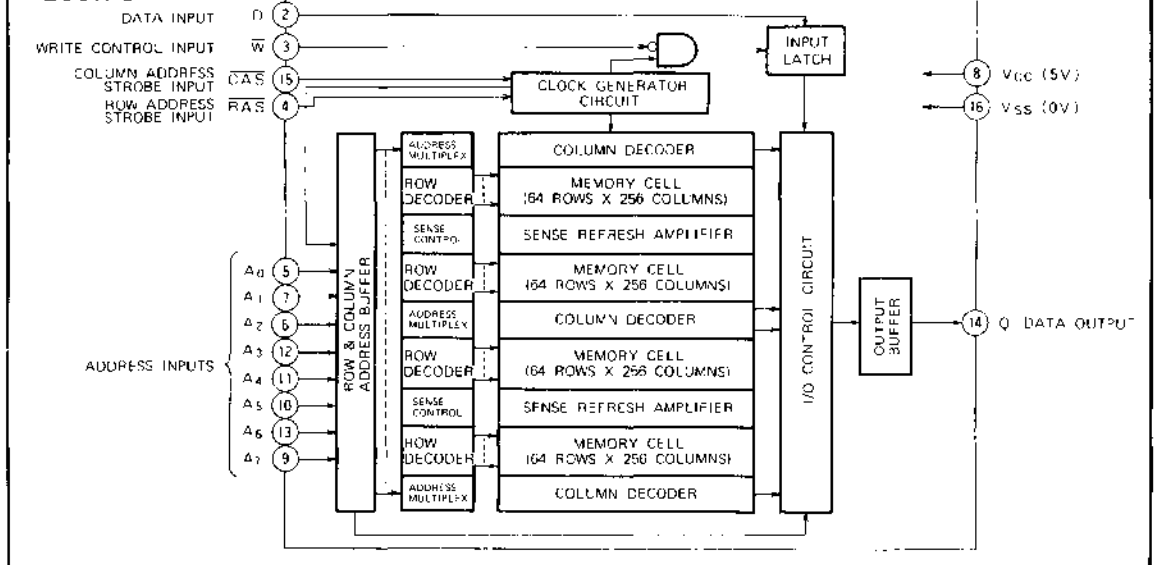

Outline 16P4

- All input terminals have low input capacitance and are directly TTL-compatible
- Output is three-state and directly TTL-compatible
- 128 refresh cycles every 2ms (16K dynamic RAMs M5K416P, S compatible)
- CAS controlled output allows hidden refresh
- Output data can be held infinitely by CAS
- Interchangeable with Mostek's MK4564 and Motorola's MCM6665 in pin configuration

APPLICATION

- Main memory unit for computers

BLOCK DIAGRAM

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

FUNCTION

The M5K4164NP provides, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, $\overline{\text{RAS}}$ -only refresh, and delayed-write. The input conditions for each are shown in Table 1.

Table 1 Input conditions for each mode

Operation	Inputs						Output		Refresh	Remarks
	$\overline{\text{RAS}}$	$\overline{\text{CAS}}$	$\overline{\text{W}}$	D	Row address	Column address	Q			
Read	ACT	ACT	NAC	DNC	APD	APD	VLD	YES	Page mode identical except refresh is NO.	
Write	ACT	ACT	ACT	VLD	APD	APD	OPN	YES		
Read-modify-write	ACT	ACT	ACT	VLD	APD	APD	VLD	YES		
$\overline{\text{RAS}}$ -only refresh	ACT	NAC	DNC	DNC	APD	DNC	OPN	YES		
Hidden refresh	ACT	ACT	DNC	DNC	APD	DNC	VLD	YES		
Standby	NAC	DNC	DNC	DNC	DNC	DNC	OPN	NO		

Note: ACT: active, NAC: nonactive, DNC: don't care, VLD: valid, APD: applied, OPN: open

SUMMARY OF OPERATIONS

Addressing

To select one of the 65536 memory cells in the M5K4164NP the 16-bit address signal must be multiplexed into 8 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{\text{RAS}}$) latches the 8 row-address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{\text{CAS}}$) latches the 8 column-address bits. Timing of the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ clocks can be selected by either of the following two methods:

1. The delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ $t_{d(\text{RAS-CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{\text{CAS}}$ control signals are inhibited almost until $t_{d(\text{RAS-CAS})\text{max}}$ ('gated $\overline{\text{CAS}}$ ' operation). The external $\overline{\text{CAS}}$ signal can be applied with a margin not affecting the on-chip circuit operations, e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\text{RAS-CAS})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of $\overline{\text{CAS}}$ has already been released, so that the internal $\overline{\text{CAS}}$ control signals are controlled by the externally applied $\overline{\text{CAS}}$, which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of $\overline{\text{W}}$ input and $\overline{\text{CAS}}$ input. Thus when the $\overline{\text{W}}$ input makes its negative transition prior to $\overline{\text{CAS}}$ input (early write), the data input is strobed by $\overline{\text{CAS}}$, and the negative transition of $\overline{\text{CAS}}$ is set as the

reference point for set-up and hold times. In the read-write or read-modify-write cycles, however, when the $\overline{\text{W}}$ input makes its negative transition after $\overline{\text{CAS}}$, the $\overline{\text{W}}$ negative transition is set as the reference point for setup and hold times.

Data Output Control

The output of the M5K4164NP is in the high-impedance state when $\overline{\text{CAS}}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until $\overline{\text{CAS}}$ goes high, irrespective of the condition of $\overline{\text{RAS}}$.

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K4164NP, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{\text{CAS}}$ pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time. This enables extremely flexible clock-timing settings for $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

3. Two Methods of Chip Selection

Since the output is not latched, $\overline{\text{CAS}}$ is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that $\overline{\text{CAS}}$ and/or $\overline{\text{RAS}}$ can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding $\overline{\text{CAS}}$, the page boundary can be extended beyond the 256 column locations in a single chip. In this case, $\overline{\text{RAS}}$ must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of $\overline{\text{RAS}}$, because once the row address has been strobed, $\overline{\text{RAS}}$ is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

Each of the 128 rows ($A_0 \sim A_6$) of the M5K4164NP must be refreshed every 2 ms to maintain data. The methods of refreshing for the M5K4164NP are as follows.

1. Normal Refresh

Read cycle and Write cycle (early write, delayed write or read-modify-write) refresh the selected row as defined by the low order ($\overline{\text{RAS}}$) addresses. Any write cycle, of course, may change the state of the selected cell. Using a read, write, or read-modify-write cycle for refresh is not recommended for systems which utilize "write-OR" outputs since output bus contention will occur.

2. $\overline{\text{RAS}}$ Only Refresh

A $\overline{\text{RAS}}$ -only refresh cycle is the recommended technique for most applications to provide for data retention. A $\overline{\text{RAS}}$ -only refresh cycle maintains the output in the high-impedance state with a typical power reduction of 20% over a read or write cycle.

3. Hidden Refresh

A feature of the M5K4164NP is that refresh cycles may be performed while maintaining valid data at the output pin by extending the $\overline{\text{CAS}}$ active time from a previous memory read cycle. This feature is referred to as hidden refresh.

Hidden refresh is performed by holding $\overline{\text{CAS}}$ at V_{IL} and taking $\overline{\text{RAS}}$ high and after a specified precharge period, executing a $\overline{\text{RAS}}$ -only cycling, but with $\overline{\text{CAS}}$ held low.

The advantage of this refresh mode is that data can be held valid at the output data port indefinitely by leaving the $\overline{\text{CAS}}$ asserted. In many applications this eliminates the need for off-chip latches.

Power Dissipation

Most of the circuitry in the M5K4164NP is dynamic, and most of the power is dissipated when addresses are strobed. Both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ are decoded and applied to the M5K4164NP as chip-select in the memory system, but if $\overline{\text{RAS}}$ is decoded, all unselected devices go into stand-by independent of the $\overline{\text{CAS}}$ condition, minimizing system power dissipation.

Power Supplies

The M5K4164NP operates on a single 5V power supply.

A wait of some 500 μ s and eight or more dummy cycles is necessary after power is applied to the device before memory operation is achieved.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage	With respect to V _{SS}	-1 ~ 7	V
V _I	Input voltage		-1 ~ 7	V
V _O	Output voltage		-1 ~ 7	V
I _O	Output current		50	mA
P _d	Power dissipation	T _a = 25°C	700	mW
T _{opr}	Operating free-air temperature range		0 ~ 70	°C
T _{stg}	Storage temperature range		-65 ~ 150	°C

RECOMMENDED OPERATING CONDITIONS (T_a = 0 ~ 70°C, unless otherwise noted) (Note 1)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V _{CC}	Supply voltage	4.5	5	5.5	V

$t_{h(CAS-RAS)}$	RAS hold time after CAS	t_{RSH}	75		100		ns
$t_d(CAS-RAS)$	Delay time, CAS to RAS (Note 9)	t_{CRP}	-20		-20		ns
$t_d(RAS-CAS)$	Delay time, RAS to CAS (Note 10)	t_{RCD}	25	75	30	100	ns
$t_{SU(RA-RAS)}$	Row address setup time before RAS	t_{ASR}	0		0		ns
$t_{SU(CA-CAS)}$	Column address setup time before CAS	t_{ASC}	-5		-5		ns
$t_{h(RAS-RA)}$	Row address hold time after RAS	t_{RAH}	20		25		ns
$t_{h(CAS-CA)}$	Column address hold time after CAS	t_{CAH}	25		35		ns
$t_{h(RAS-CA)}$	Column address hold time after RAS	t_{AR}	95		120		ns
t_{TLH}	Transition time	t_T	3	35	3	50	ns
t_{TLH}							

2

- Note 5: An initial pause of 500 μ s is required after power-up followed by any eight RAS or RAS/CAS cycles before proper device operation is achieved.
 Note 6: The switching characteristics are defined as $t_{TLH} = t_{TLH} - 5\text{ns}$.
 Note 7: Reference levels of input signals are $V_{IH \text{ min}}$ and $V_{IL \text{ max}}$. Reference levels for transition time are also between V_{IH} and V_{IL} .
 Note 8: Except for page-mode.
 Note 9: $t_d(\text{CAS-RAS})$ requirement is only applicable for RAS/CAS cycles preceded by a CAS only cycle (i.e., for systems where CAS has not been decoded with RAS).
 Note 10: Operation within the $t_d(\text{RAS-CAS})$ max limit insures that $t_a(\text{RAS})$ max can be met. $t_d(\text{RAS-CAS})$ max is specified reference point only; if $t_d(\text{RAS-CAS})$ is greater than the specified $t_d(\text{RAS-CAS})$ max limit, then access time is controlled exclusively by $t_a(\text{CAS})$.
 $t_d(\text{RAS-CAS})_{\text{min}} = t_h(\text{RAS-RA})_{\text{min}} + 2t_{TLH}(t_{TLH}) + t_{SU}(\text{CA-CAS})_{\text{min}}$.

SWITCHING CHARACTERISTICS ($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted)

Read Cycle

Symbol	Parameter	Alternative Symbol	M5K4164NP-15		M5K4164NP-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{CR}	Read cycle time	t_{RC}	260		330		ns
$t_{SU(R-CAS)}$	Read setup time before CAS	t_{RCS}	0		0		ns
$t_{h(CAS-R)}$	Read hold time after CAS (Note 11)	t_{RCH}	0		0		ns
$t_{h(RAS-R)}$	Read hold time after RAS (Note 11)	t_{RRH}	20		25		ns
$t_{dis(CAS)}$	Output disable time (Note 12)	t_{OFF}	0	40	0	50	ns
$t_a(CAS)$	CAS access time (Note 13)	t_{CAC}		75		100	ns
$t_a(RAS)$	RAS access time (Note 14)	t_{RAC}		150		200	ns

- Note 11: Either $t_{h(RAS-R)}$ or $t_{h(CAS-R)}$ must be satisfied for a read cycle.
 Note 12: $t_{dis(CAS)}_{\text{max}}$ defines the time at which the output achieves the open circuit condition and is not reference to V_{OH} or V_{OL} .
 Note 13: This is the value when $t_d(\text{RAS-CAS}) \geq t_d(\text{RAS-CAS})_{\text{max}}$. Test conditions: Load = 2T TL, $C_L = 100\text{pF}$.
 Note 14: This is the value when $t_d(\text{RAS-CAS}) < t_d(\text{RAS-CAS})_{\text{max}}$. When $t_d(\text{RAS-CAS}) \geq t_d(\text{RAS-CAS})_{\text{max}}$, $t_a(\text{RAS})$ will increase by the amount that $t_d(\text{RAS-CAS})$ exceeds the value shown. Test conditions: Load = 2T TL, $C_L = 100\text{pF}$.

$t_{dis} (CAS)$	Output disable time	t_{OFF}	0	40	0	50	ns
$t_a (CAS)$	\overline{CAS} access time (Note 13)	t_{CAC}		75		100	ns
$t_a (RAS)$	\overline{RAS} access time (Note 14)	t_{RAC}		150		200	ns

Note 15: t_{ORWmin} is defined as $t_{ORWmin} = t_d (RAS-W) + t_h (W-RAS) + t_w (RASH) + 3t_{TLH}(I_{THL})$

16: $t_{ORMWmin}$ is defined as $t_{ORMWmin} = t_a (RAS)_{max} + t_h (W-RAS) + t_w (RASH) + 3t_{TLH}(I_{THL})$

17: $t_{su} (W-CAS)$, $t_d (RAS-W)$, and $t_d (CAS-W)$ do not define the limits of operation, but are included as electrical characteristics only.

When $t_{su} (W-CAS) \geq t_{su} (W-CAS)_{min}$, an early-write cycle is performed, and the data output keeps the high-impedance state.

When $t_d (RAS-W) \geq t_d (RAS-W)_{min}$, and $t_d (CAS-W) \geq t_{su} (W-CAS)_{min}$ a read-write cycle is performed, and the data of the selected address will be read out on the data output.

For all conditions other than those described above, the condition of data output (at access time and until \overline{CAS} goes back to V_{IH}) is not defined.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

DESCRIPTION

This is a family of 65 536-word by 1-bit dynamic RAMs, fabricated with the high performance N-channel silicon-gate MOS process, and is ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer polysilicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities. The M5K4164S operates on a 5V power supply using the on-chip substrate bias generator.

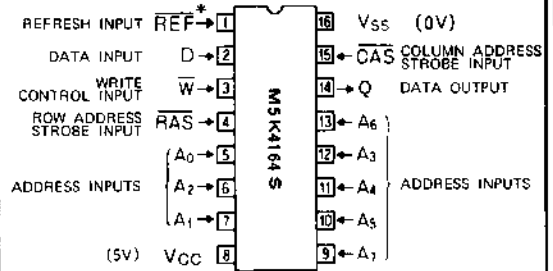

FEATURES

- Performance ranges

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K4164S-15	150	260	200
M5K4164S-20	200	330	170

- Standard 16-pin package
- Single 5V ±10% supply
- Low standby power dissipation: 28mW (max)
- Low operating power dissipation:
 - M5K4164S-15 275mW (max)
 - M5K4164S-20 250mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary
- Early-write operation gives common I/O capability
- Read-modify-write, \overline{RAS} -only refresh, and page-mode capabilities

PIN CONFIGURATION (TOP VIEW)

Outline 16S1

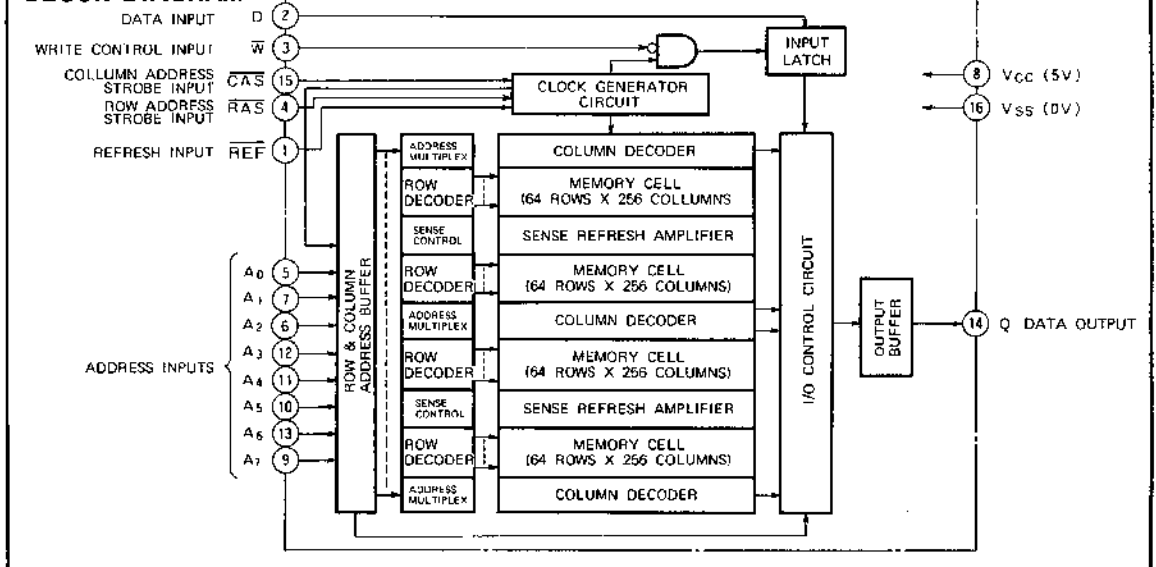

* If the pin 1 (\overline{REF}) function is not used, pin 1 may be left open (not connect).

- All input terminals have low input capacitance and are directly TTL-compatible
- Output is three-state and directly TTL-compatible
- 128 refresh cycles every 2ms (16K dynamic RAMs M5K4116P, S compatible)
- Pin 1 controls automatic- and self-refresh mode.
- \overline{CAS} controlled output allows hidden refresh, hidden automatic refresh and hidden self-refresh.
- Output data can be held infinitely by \overline{CAS} .
- Interchangeable with Mostek's MK4164 and Motorola's MCM 6664 in pin configuration.

APPLICATION

- Main memory unit for computers.

BLOCK DIAGRAM

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

FUNCTION

The M5K4164S provides, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, $\overline{\text{RAS}}$ -only refresh, and delayed-write. The input conditions for each are shown in Table 1.

Table 1 Input conditions for each mode

Operation	Inputs							Output		Refresh	Remarks
	$\overline{\text{RAS}}$	$\overline{\text{CAS}}$	$\overline{\text{W}}$	D	Row address	Column address	$\overline{\text{REF}}$	Q			
Read	ACT	ACT	NAC	DNC	APD	APD	NAC	VLD	YES	Page mode identical except refresh is NO.	
Write	ACT	ACT	ACT	VLD	APD	APD	NAC	OPN	YES		
Read-modify-write	ACT	ACT	ACT	VLD	APD	APD	NAC	VLD	YES		
$\overline{\text{RAS}}$ -only refresh	ACT	NAC	DNC	DNC	APD	DNC	NAC	OPN	YES		
Hidden refresh	ACT	ACT	DNC	DNC	APD	DNC	NAC	VLD	YES		
Automatic refresh	NAC	DNC	DNC	DNC	DNC	DNC	ACT	OPN	YES		
Self refresh	NAC	DNC	DNC	DNC	DNC	DNC	ACT	OPN	YES		
Hidden automatic refresh	NAC	ACT	DNC	DNC	DNC	DNC	ACT	VLD	YES		
Hidden self refresh	NAC	ACT	DNC	DNC	DNC	DNC	ACT	VLD	YES		
Standby	NAC	DNC	DNC	DNC	DNC	DNC	NAC	OPN	NO		

Note: ACT : active, NAC : nonactive, DNC : don't care, VLD : valid, APD : applied, OPN : open.

SUMMARY OF OPERATIONS

Addressing

To select one of the 65 536 memory cells in the M5K4164S the 16-bit address signal must be multiplexed into 8 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{\text{RAS}}$) latches the 8 row-address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{\text{CAS}}$) latches the 8 column-address bits. Timing of the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ clocks can be selected by either of the following two methods:

1. The delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ $t_{d(\text{RAS-CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{\text{CAS}}$ control signals are inhibited almost until $t_{d(\text{RAS-CAS})\text{max}}$ ('gated $\overline{\text{CAS}}$ ' operation). The external $\overline{\text{CAS}}$ signal can be applied with a margin not affecting the on-chip circuit operations, e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\text{RAS-CAS})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of $\overline{\text{CAS}}$ has already been released, so that the internal $\overline{\text{CAS}}$ control signals are controlled by the externally applied $\overline{\text{CAS}}$, which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of $\overline{\text{W}}$ input and $\overline{\text{CAS}}$ input. Thus when the $\overline{\text{W}}$ input makes its negative transition prior to $\overline{\text{CAS}}$ input (early write), the data input is strobed by $\overline{\text{CAS}}$, and the negative transition of $\overline{\text{CAS}}$ is set as the reference point for set-up and hold times. In the read-write

or read-modify-write cycles, however, when the $\overline{\text{W}}$ input makes its negative transition after $\overline{\text{CAS}}$, the $\overline{\text{W}}$ negative transition is set as the reference point for setup and hold times.

Data Output Control

The output of the M5K4164S is in the high-impedance state when $\overline{\text{CAS}}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until $\overline{\text{CAS}}$ goes high, irrespective of the condition of $\overline{\text{RAS}}$.

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K4164S, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{\text{CAS}}$ pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time. This enables extremely flexible clock-timing settings for $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

2

3. Two Methods of Chip Selection

Since the output is not latched, \overline{CAS} is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that \overline{CAS} and/or \overline{RAS} can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding \overline{CAS} , the page boundary can be extended beyond the 256 column locations in a single chip. In this case, \overline{RAS} must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of \overline{RAS} , because once the row address has been strobed, \overline{RAS} is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

Each of the 128 rows ($A_0 \sim A_6$) of the M5K4164S must be refreshed every 2 ms to maintain data. The methods of refreshing for the M5K4164S are as follows.

1. Normal Refresh

Read cycle and Write cycle (early write, delayed write or read-modify-write) refresh the selected row as defined by the low order (\overline{RAS}) addresses. Any write cycle, of course, may change the state of the elected cell. Using a read, write, or read-modify-write cycle for refresh is not recommended for systems which utilize "wire-OR" outputs since output bus contention will occur.

2. \overline{RAS} Only Refresh

A \overline{RAS} -only refresh cycle is the recommended technique for most applications to provide for data retention. A \overline{RAS} -only refresh cycle maintains the output in the high-impedance state with a typical power reduction of 20% over a read or write cycle.

3. Automatic Refresh

Pin 1 (\overline{REF}) has two special functions. The M5K4164S has a refresh address counter, refresh address multiplexer and refresh timer for these operations. Automatic refresh is initiated by bringing \overline{REF} low after \overline{RAS} has precharged and is used during standard operation just like \overline{RAS} -only refresh, except that sequential row addresses from an external counter are no longer necessary.

At the end of automatic refresh cycle, the internal refresh address counter will be automatically incremented. The output state of the refresh address counter is initiated by some eight \overline{REF} , \overline{RAS} or $\overline{RAS}/\overline{CAS}$ cycles after power is applied. Therefore, a special operation is not necessary to initiate it.

\overline{RAS} must remain inactive during \overline{REF} activated cycles. Likewise, \overline{REF} must remain inactive during \overline{RAS} generated cycle.

4. Self-Refresh

The other function of pin 1 (\overline{REF}) is self-refresh. Timing for self-refresh is quite similar to that for automatic refresh. As long as \overline{RAS} remains high and \overline{REF} remains low, the M5K4164S will refresh itself. This internal sequence repeats asynchronously every 12 to 16 μ s. After 2 ms, the on-chip refresh address counter has advanced through all the row addresses and refreshed the entire memory. Self-refresh is primarily intended for trouble free power-down operation.

For example, when battery backup is used to maintained data integrity in the memory, \overline{REF} may be used to place the device in the self-refresh mode with no external timing signals necessary to keep the information alive.

In summary, the pin 1 (\overline{REF}) refresh function gives the user a feature that is free, save him hardware on the board, and in fact, will simplify his battery backup procedures, increase his battery life, and save him overall cost while giving him improved system performance.

There is an internal pullup resistor ($\approx 3M\Omega$) on pin 1, so if the pin 1 (\overline{REF}) function is not used, pin 1 may be left open (not connect) without affecting the normal operations.

5. Hidden Refresh

A features of the M5K4164S is that refresh cycle may be performed while maintaining valid data at the output pin by extending the \overline{CAS} active time from a previous memory read cycle. This feature is referred to as hidden refresh.

Hidden refresh is performed by holding \overline{CAS} at V_{IL} and taking \overline{RAS} high and after a specified precharge period, executing a \overline{RAS} -only cycling, automatic refresh and self-refresh, but with \overline{CAS} held low.

The advantage of this refresh mode is that data can be held valid at the output data port indefinitely by leaving the \overline{CAS} asserted. In many applications this eliminates the need for off-chip latches.

Power Dissipation

Most of the circuitry in the M5K4164S is dynamic, and most of the power is dissipated when addresses are strobed. Both \overline{RAS} and \overline{CAS} are decoded and applied to the M5K4164S as chip-select in the memory system, but if \overline{RAS} is decoded, all unselected devices go into stand-by independent of the \overline{CAS} condition, minimizing system power dissipation.

Power Supplies

The M5K4164S operates on a single 5V power supply.

A wait of some 500 μ s and eight or more dummy cycle is necessary after power is applied to the device before memory operation is achieved.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage	With respect to V _{SS}	-1~7	V

$t_{SU}(\text{CA-CAS})$	Column address setup time before CAS	t_{ASC}	-5		-5		ns
$t_h(\text{RAS-RA})$	Row address hold time after RAS	t_{RAH}	20		25		ns
$t_h(\text{CAS-CA})$	Column address hold time after CAS	t_{CAH}	25		35		ns
$t_h(\text{RAS-CA})$	Column address hold time after RAS	t_{AR}	95		120		ns
t_{TLH}	Transition time	t_T	3	35	3	50	ns
t_{TLH}							

2

- Note 5: An initial pause of 500 μ s is required after power-up followed by any eight REF, RAS or RAS/CAS cycles before proper device operation is achieved.
 Note 6: The switching characteristics are defined as $t_{TLH} = t_{TLH} = 5\text{ns}$.
 Note 7: Reference levels of input signals are $V_{IH \text{ min}}$ and $V_{IL \text{ max}}$. Reference levels for transition time are also between V_{IH} and V_{IL} .
 Note 8: Except for page-mode.
 Note 9: $t_d(\text{CAS-RAS})$ requirement is only applicable for RAS/CAS cycles preceded by a CAS only cycle (i. e. for systems where CAS has not been decoded with RAS).
 Note 10: Operation within the $t_d(\text{RAS-CAS})_{\text{max}}$ limit insures that $t_a(\text{RAS})_{\text{max}}$ can be met. $t_d(\text{RAS-CAS})_{\text{max}}$ is specified reference point only; if $t_d(\text{RAS-CAS})$ is greater than the specified $t_d(\text{RAS-CAS})_{\text{max}}$ limit, then access time is controlled exclusively by $t_a(\text{CAS})$.
 $t_d(\text{RAS-CAS})_{\text{min}} = t_h(\text{RAS-RA})_{\text{min}} + 2(t_{TLH} + t_{TLH}) - t_{SU}(\text{CA-CAS})_{\text{min}}$.

SWITCHING CHARACTERISTICS ($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted)

Read Cycle

Symbol	Parameter	Alternative Symbol	M5K4164S-15		M5K4164S-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{CR}	Read cycle time	t_{RC}	260		330		ns
$t_{SU}(\text{R-CAS})$	Read setup time before CAS	t_{RCS}	0		0		ns
$t_h(\text{CAS-R})$	Read hold time after CAS (Note 11)	t_{ROH}	0		0		ns
$t_h(\text{RAS-R})$	Read hold time after RAS (Note 11)	t_{RRH}	20		25		ns
$t_{DIS}(\text{CAS})$	Output disable time (Note 12)	t_{OFF}	0	40	0	50	ns
$t_a(\text{CAS})$	CAS access time (Note 13)	t_{CAC}		75		100	ns
$t_a(\text{RAS})$	RAS access time (Note 14)	t_{RAC}		150		200	ns

- Note 11: Either $t_h(\text{RAS-R})$, or $t_h(\text{CAS-R})$ must be satisfied for a read cycle.
 Note 12: $t_{DIS}(\text{CAS})_{\text{max}}$ defines the time at which the output achieves the open circuit condition and is not reference to V_{OH} or V_{OL} .
 Note 13: This is the value when $t_d(\text{RAS-CAS}) \geq t_d(\text{RAS-CAS})_{\text{max}}$. Test conditions; Load = 2TTL, $C_L = 100\text{pF}$.
 Note 14: This is the value when $t_d(\text{RAS-CAS}) < t_d(\text{RAS-CAS})_{\text{max}}$. When $t_d(\text{RAS-CAS}) \geq t_d(\text{RAS-CAS})_{\text{max}}$, $t_a(\text{RAS})$ will increase by the amount that $t_d(\text{RAS-CAS})$ exceeds the value shown. Test conditions; Load = 2TTL, $C_L = 100\text{pF}$.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

Read-Write and Read-Modify-Write Cycles

Symbol	Parameter	Alternative Symbol	M5K4164S-15		M5K4164S-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t _{ORW}	Read-write cycle time (Note 15)	t _{RWC}	280		340		ns
t _{ORMW}	Read-modify-write cycle time (Note 16)	t _{RMWC}	310		390		ns
t _{h(W-RAS)}	RAS hold time after write	t _{RWL}	45		55		ns
t _{h(W-CAS)}	CAS hold time after write	t _{OWL}	45		55		ns
t _{w(W)}	Write pulse width	t _{WP}	45		55		ns
t _{SU(R-CAS)}	Read setup time before CAS	t _{RCS}	0		0		ns
t _{d(RAS-W)}	Delay time, RAS to write (Note 17)	t _{RWD}	120		150		ns
t _{d(CAS-W)}	Delay time, CAS to write (Note 18)	t _{CWD}	60		80		ns
t _{SU(D-W)}	Data-in set-up time before write	t _{DS}	0		0		ns
t _{h(W-D)}	Data-in hold time after write	t _{DH}	45		55		ns
t _{dis(CAS)}	Output disable time	t _{OFF}	0	40	0	50	ns
t _{a(CAS)}	CAS access time (Note 13)	t _{CAC}		75		100	ns
t _{a(RAS)}	RAS access time (Note 14)	t _{RAC}		150		200	ns

Note 15: t_{ORWmin} is defined as t_{ORWmin} = t_{d(RAS-W)} + t_{h(W-RAS)} + t_{w(RAS)} + 3t_{TLH(t_{THL})}

16: t_{ORMWmin} is defined as t_{ORMWmin} = t_{a(RAS)max} + t_{h(W-RAS)} + t_{w(RAS)} + 3t_{TLH(t_{THL})}

17: t_{SU(W-CAS)}, t_{d(RAS-W)}, and t_{d(CAS-W)} do not define the limits of operation, but are included as electrical characteristics only.

When t_{SU(W-CAS)} ≥ t_{SU(W-CAS)min}, an early-write cycle is performed, and the data output keeps the high-impedance state.

When t_{d(RAS-W)} ≥ t_{d(RAS-W)min}, and t_{d(CAS-W)} ≥ t_{SU(W-CAS)min} a read-write cycle is performed, and the data of the selected address will be read out on the data output.

For all conditions other than those described above, the condition of data output (at access time and until CAS goes back to V_{1H}) is not defined.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

DESCRIPTION

This is a family of 65 536-word by 1-bit dynamic RAMs, fabricated with the high performance N-channel silicongate MOS process, and is ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer polysilicon process technology and a single-transistor dynamic storage cell provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address inputs permit both a reduction in pins to the standard 16-pin package configuration and an increase in system densities. The M5K4164NS operates on a 5V power supply using the on-chip substrate bias generator.

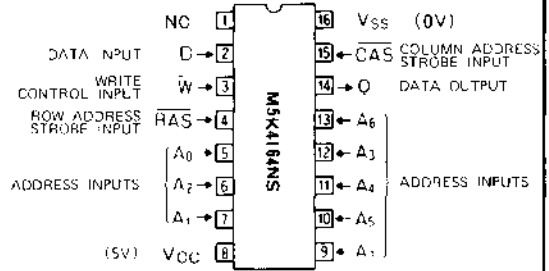

FEATURES

• Performance ranges

Type name	Access time (max) (ns)	Cycle time (min) (ns)	Power dissipation (typ) (mW)
M5K4164NS-15	150	260	200
M5K4164NS-20	200	330	170

- Standard 16-pin package
- Single 5V±10% supply
- Low standby power dissipation: 28.0mW (max)
- Low operating power dissipation:
 - M5K4164NS-15 275mW (max)
 - M5K4164NS-20 250mW (max)
- Unlatched output enables two-dimensional chip selection and extended page boundary
- Early-write operation gives common I/O capability
- Read-modify-write, RAS-only refresh, and page-mode capabilities

PIN CONFIGURATION (TOP VIEW)

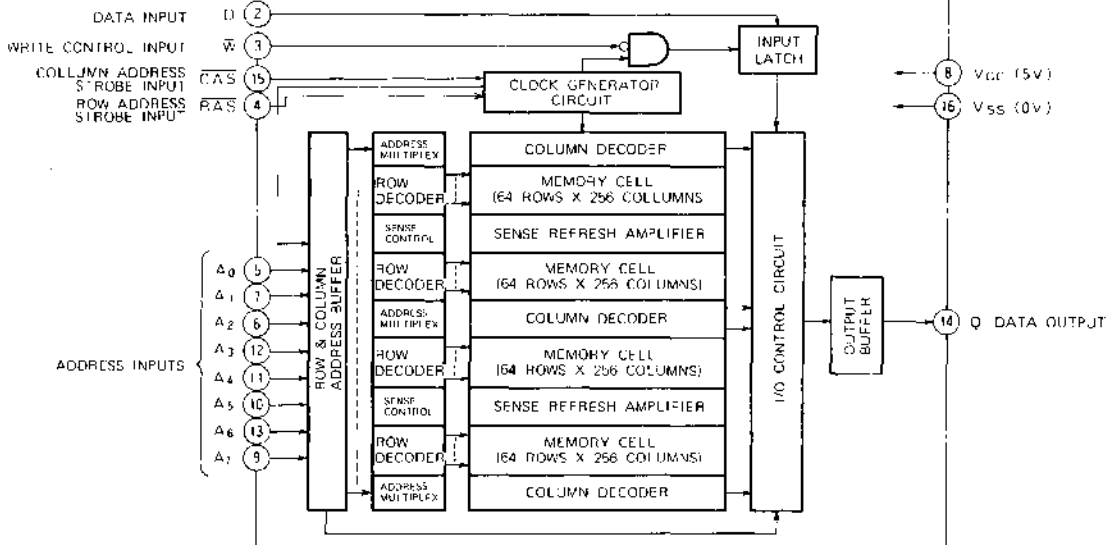

Outline 16S1

- All input terminals have low input capacitance and are directly TTL-compatible
- Output is three-state and directly TTL-compatible
- 128 refresh cycles every 2ms (16K dynamic RAMs M5K4116P, S compatible)
- CAS controlled output allows hidden refresh.
- Output data can be held infinitely by $\overline{\text{CAS}}$.
- Interchangeable with Mostek's MK4564 and Motorola's MCM 6665 in pin configuration.

APPLICATION

- Main memory unit for computers.

BLOCK DIAGRAM

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

FUNCTION

The M5K4164NS provides, in addition to normal read, write, and read-modify-write operations, a number of other functions, e.g., page mode, $\overline{\text{RAS}}$ -only refresh, and delayed-write. The input conditions for each are shown in Table 1.

Table 1 Input conditions for each mode

Operation	Inputs						Output	Refresh	Remarks
	$\overline{\text{RAS}}$	$\overline{\text{CAS}}$	$\overline{\text{W}}$	D	Row address	Column address	Q		
Read	ACT	ACT	NAC	DNC	APD	APD	VLD	YES	Page mode identical except refresh is NO
Write	ACT	ACT	ACT	VLD	APD	APD	OPN	YES	
Read-modify-write	ACT	ACT	ACT	VLD	APD	APD	VLD	YES	
$\overline{\text{RAS}}$ -only refresh	ACT	NAC	DNC	DNC	APD	DNC	OPN	YES	
Hidden refresh	ACT	ACT	DNC	DNC	APD	DNC	VLD	YES	
Standby	NAC	DNC	DNC	DNC	DNC	DNC	OPN	NO	

Note: ACT : active, NAC : nonactive, DNC : don't care, VLD : valid, APD : applied, OPN : open.

SUMMARY OF OPERATIONS

Addressing

To select one of the 65536 memory cells in the M5K4164NS the 16-bit address signal must be multiplexed into 8 address signals, which are then latched into the on-chip latch by two externally-applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{\text{RAS}}$) latches the 8 row-address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{\text{CAS}}$) latches the 8 column-address bits. Timing of the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ clocks can be selected by either of the following two methods:

1. The delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ $t_{d(\text{RAS-CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{\text{CAS}}$ control signals are inhibited almost until $t_{d(\text{RAS-CAS})\text{max}}$ ('gated $\overline{\text{CAS}}$ ' operation). The external $\overline{\text{CAS}}$ signal can be applied with a margin not affecting the on-chip circuit operations, e.g. access time, and the address inputs can be easily changed from row address to column address.
2. The delay time $t_{d(\text{RAS-CAS})}$ is set larger than the maximum value of the limits. In this case the internal inhibition of $\overline{\text{CAS}}$ has already been released, so that the internal $\overline{\text{CAS}}$ control signals are controlled by the externally applied $\overline{\text{CAS}}$, which also controls the access time.

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions of $\overline{\text{W}}$ input and $\overline{\text{CAS}}$ input. Thus when the $\overline{\text{W}}$ input makes its negative transition prior to $\overline{\text{CAS}}$ input (early write), the data input is strobed by $\overline{\text{CAS}}$, and the negative transition of $\overline{\text{CAS}}$ is set as the

reference point for set-up and hold times. In the read-write or read-modify-write cycles, however, when the $\overline{\text{W}}$ input makes its negative transition after $\overline{\text{CAS}}$, the $\overline{\text{W}}$ negative transition is set as the reference point for setup and hold times.

Data Output Control

The output of the M5K4164NS is in the high-impedance state when $\overline{\text{CAS}}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until $\overline{\text{CAS}}$ goes high, irrespective of the condition of $\overline{\text{RAS}}$.

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

These output conditions, of the M5K4164NS, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{\text{CAS}}$ pulse in a read cycle, offer capabilities for a number of applications, as follows.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time. This enables extremely flexible clock-timing settings for $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM**3. Two Methods of Chip Selection**

Since the output is not latched, $\overline{\text{CAS}}$ is not required to keep the outputs of selected chips in the matrix in a high-impedance state. This means that $\overline{\text{CAS}}$ and/or $\overline{\text{RAS}}$ can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding $\overline{\text{CAS}}$, the page boundary can be extended beyond the 256 column locations in a single chip. In this case, $\overline{\text{RAS}}$ must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of $\overline{\text{RAS}}$, because once the row address has been strobed, $\overline{\text{RAS}}$ is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing the access and cycle times.

Refresh

Each of the 128 rows ($A_0 \sim A_6$) of the M5K4164NS must be refreshed every 2 ms to maintain data. The methods of refreshing for the M5K4164NS are as follows.

1. Normal Refresh

Read cycle and Write cycle (early write, delayed write or read-modify-write) refresh the selected row as defined by the low order ($\overline{\text{RAS}}$) addresses. Any write cycle, of course, may change the state of the selected cell. Using a read, write, or read-modify-write cycle for refresh is not recommended for systems which utilize "write-OR" outputs since output bus contention will occur.

2. $\overline{\text{RAS}}$ Only Refresh

A $\overline{\text{RAS}}$ -only refresh cycle is the recommended technique for most applications to provide for data retention. A $\overline{\text{RAS}}$ -only refresh cycle maintains the output in the high-impedance state with a typical power reduction of 20% over a read or write cycle.

3. Hidden Refresh

A feature of the M5K4164NS is that refresh cycles may be performed while maintaining valid data at the output pin by extending the $\overline{\text{CAS}}$ active time from a previous memory read cycle. This feature is referred to as hidden refresh.

Hidden refresh is performed by holding $\overline{\text{CAS}}$ at V_{1L} and taking $\overline{\text{RAS}}$ high and after a specified precharge period, executing a $\overline{\text{RAS}}$ -only cycling, but with $\overline{\text{CAS}}$ held low.

The advantage of this refresh mode is that data can be held valid at the output data port indefinitely by leaving the $\overline{\text{CAS}}$ asserted. In many applications this eliminates the need for off-chip latches.

Power Dissipation

Most of the circuitry in the M5K4164NS is dynamic, and most of the power is dissipated when addresses are strobed. Both $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ are decoded and applied to the M5K4164NS as chip-select in the memory system, but if $\overline{\text{RAS}}$ is decoded, all unselected devices go into stand-by independent of the $\overline{\text{CAS}}$ condition, minimizing system power dissipation.

Power Supplies

The M5K4164NS operates on a single 5V power supply.

A wait of some 500 μ s and eight or more dummy cycles is necessary after power is applied to the device before memory operation is achieved.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage	With respect to V _{SS}	-1 ~ 7	V
V _I	Input voltage		-1 ~ 7	V
V _O	Output voltage		-1 ~ 7	V

I _{CC4(AV)}	Average supply current from V _{CC} , page mode (Note 3, 4)	M5K4164NS-15	$\overline{RAS} = V_{IL}$, \overline{CAS} cycling		40	mA
		M5K4164NS-20	t _{CP0} = min., output open		35	mA
C _{I(A)}	Input capacitance, address inputs				5	pF
C _{I(D)}	Input capacitance, data input	V _I = V _{SS}			5	pF
C _{I(W)}	Input capacitance, write control input	f = 1MHz			7	pF
C _{I(RAS)}	Input capacitance, \overline{RAS} input	V _I = 25mVrms			10	pF
C _{I(CAS)}	Input capacitance, \overline{CAS} input				10	pF
C _O	Output capacitance	V _O = V _{SS} , f = 1MHz, V _I = 25mVrms			7	pF

Note 2: Current flowing into an IC is positive, out is negative.

3: I_{CC1(AV)}, I_{CC3(AV)}, and I_{CC4(AV)} are dependent on cycle rate. Maximum current is measured at the fastest cycle rate.

4: I_{CC1(AV)} and I_{CC4(AV)} are dependent on output loading. Specified values are obtained with the output open.

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

TIMING REQUIREMENTS (For Read, Write, Read-Modify-Write, Refresh, and Page-Mode Cycle)

($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted. See notes 5, 6 and 7.)

Symbol	Parameter	Alternative Symbol	M5K4164NS-15		M5K4164NS-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{CRF}	Refresh cycle time	t_{REF}		2		2	ms
$t_{W(RAS-H)}$	RAS high pulse width	t_{RP}	100		120		ns
$t_{W(RAS-L)}$	RAS low pulse width	t_{RAS}	150	10000	200	10000	ns
$t_{W(CAS-L)}$	CAS low pulse width	t_{CAS}	75	∞	100	∞	ns
$t_{W(CAS-H)}$	CAS high pulse width (Note 8)	t_{CPN}	35		40		ns
$t_{H(RAS-CAS)}$	CAS hold time after RAS	t_{CSH}	150		200		ns
$t_{H(CAS-RAS)}$	RAS hold time after CAS	t_{RSH}	75		100		ns
$t_d(CAS-RAS)$	Delay time, CAS to RAS (Note 9)	t_{CRP}	-20		-20		ns
$t_d(RAS-CAS)$	Delay time, RAS to CAS (Note 10)	t_{RCD}	25	75	30	100	ns
$t_{SU(RA-RAS)}$	Row address setup time before RAS	t_{ASR}	0		0		ns
$t_{SU(CA-CAS)}$	Column address setup time before CAS	t_{ASC}	-5		-5		ns
$t_{H(RAS-RA)}$	Row address hold time after RAS	t_{RAH}	20		25		ns
$t_{H(CAS-CA)}$	Column address hold time after CAS	t_{CAH}	25		35		ns
$t_{H(RAS-CA)}$	Column address hold time after RAS	t_{AR}	95		120		ns
t_{TLH}	Transition time	t_T	3	35	3	50	ns
t_{TLH}							

- Note 5: An initial pause of 500 μs is required after power-up followed by any eight RAS or RAS/CAS cycles before proper device operation is achieved.
 6: The switching characteristics are defined as $t_{THL} = t_{TLH} = 5\text{ns}$.
 7: Reference levels of input signals are V_{IH} min. and V_{IL} max. Reference levels for transition time are also between V_{IH} and V_{IL} .
 8: Except for page mode.
 9: $t_d(CAS-RAS)$ requirement is only applicable for RAS/CAS cycles preceded by a CAS only cycle (i.e. for systems where CAS has not been decoded with RAS).
 10: Operation within the $t_d(RAS-CAS)$ max limit insures that $t_a(RAS)$ max can be met. $t_d(RAS-CAS)$ max is specified reference point only; if $t_d(RAS-CAS)$ is greater than the specified $t_d(RAS-CAS)$ max limit, then access time is controlled exclusively by $t_a(CAS)$.
 $t_d(RAS-CAS)$ min = $t_{H(RAS-RA)}$ min + $2t_{THL}$ (t_{TLH}) - $t_{SU(CA-CAS)}$ min.

SWITCHING CHARACTERISTICS ($T_a = 0 \sim 70^\circ\text{C}$, $V_{CC} = 5\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, unless otherwise noted.)

Read Cycle

Symbol	Parameter	Alternative Symbol	M5K4164NS-15		M5K4164NS-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t_{CR}	Read cycle time	t_{RC}	260		330		ns
$t_{SU(R-CAS)}$	Read setup time before CAS	t_{RCS}	0		0		ns
$t_{H(CAS-R)}$	Read hold time after CAS (Note 11)	t_{ROH}	0		0		ns
$t_{H(RAS-R)}$	Read hold time after RAS (Note 11)	t_{RRH}	20		25		ns
$t_{DIS(CAS)}$	Output disable time (Note 12)	t_{OPF}	0	40	0	50	ns
$t_a(CAS)$	CAS access time (Note 13)	t_{CAC}		75		100	ns
$t_a(RAS)$	RAS access time (Note 14)	t_{RAC}		150		200	ns

- Note 11: Either $t_{H(RAS-R)}$ or $t_{H(CAS-R)}$ must be satisfied for a read cycle.
 Note 12: $t_{DIS(CAS)}$ max defines the time at which the output achieves the open circuit condition and is not reference to V_{OH} or V_{OL} .
 Note 13: This is the value when $t_d(RAS-CAS) \geq t_d(RAS-CAS)$ max. Test conditions: Load = 2TTL, $C_L = 100\text{pF}$.
 Note 14: This is the value when $t_d(RAS-CAS) < t_d(RAS-CAS)$ max. When $t_d(RAS-CAS) \geq t_d(RAS-CAS)$ max, $t_a(RAS)$ will increase by the amount that $t_d(RAS-CAS)$ exceeds the value shown. Test conditions: Load = 2TTL, $C_L = 100\text{pF}$.

Read-Write and Read-Modify-Write Cycles

Symbol	Parameter	Alternative Symbol	M5K4164NS-15		M5K4164NS-20		Unit
			Limits		Limits		
			Min	Max	Min	Max	
t _{ORW}	Read-write cycle time (Note 15)	t _{RWC}	280		340		ns
t _{ORMW}	Read-modify-write cycle time (Note 16)	t _{RMWC}	310		390		ns
t _{h(W-RAS)}	RAS hold time after write	t _{RWL}	45		55		ns
t _{h(W-CAS)}	CAS hold time after write	t _{CWL}	45		55		ns
t _{w(W)}	Write pulse width	t _{WP}	45		55		ns
t _{SU(R-CAS)}	Read setup time before CAS	t _{RCS}	0		0		ns
t _{d(RAS-W)}	Delay time, RAS to write (Note 17)	t _{RWD}	120		150		ns
t _{d(CAS-W)}	Delay time, CAS to write (Note 17)	t _{CWD}	60		80		ns
t _{SU(D-W)}	Data-in set-up time before write	t _{DS}	0		0		ns
t _{h(W-D)}	Data-in hold time after write	t _{DH}	45		55		ns
t _{dIS(CAS)}	Output disable time	t _{OFF}	0	40	0	50	ns
t _{a(CAS)}	CAS access time (Note 13)	t _{CAC}		75		100	ns
t _{a(RAS)}	RAS access time (Note 14)	t _{RAC}		150		200	ns

Note 15: t_{ORW min} is defined as t_{ORW min} = t_{d(RAS-W)} + t_{h(W-RAS)} + t_{w(RASH)} + 3t_{TLH(t_{THL})}

16: t_{ORMW min} is defined as t_{ORMW min} = t_{a(RAS)max} + t_{h(W-RAS)} + t_{w(RASH)} + 3t_{TLH(t_{THL})}

17: t_{SU(W-CAS)}, t_{d(RAS-W)}, and t_{d(CAS-W)} do not define the limits of operation, but are included as electrical characteristics only.

When t_{SU(W-CAS)} ≥ t_{SU(W-CAS)min}, an early write cycle is performed, and the data output keeps the high-impedance state.

When t_{d(RAS-W)} ≥ t_{d(RAS-W)min}, and t_{d(CAS-W)} ≥ t_{SU(W-CAS)min}, a read-write cycle is performed, and the data of the selected address will be read out on the data output.

For all conditions other than those described above, the condition of data output (at access time and until CAS goes back to V_{TH}) is not defined.

Page-Mode Cycle

65 536-BIT (65 536-WORD BY 1-BIT) DYNAMIC RAM

4096-BIT (1024-WORD BY 4-BIT) STATIC RAM

DESCRIPTION

This is a family of 4096-bit static RAMs organized as 1024 words of 4 bits and designed for simple interfacing. They are fabricated using N-channel silicon-gate MOS technology. They operate with a single 5V supply, as does TTL, and the inputs and outputs are directly TTL compatible. I/O terminals are common.

FEATURES

Parameter	MSL 2114LP-2	MSL 2114LP-3	MSL 2114LP
Access time (max)	200ns	300ns	450ns
Cycle time (min)	200ns	300ns	450ns

- Low power dissipation: 50 μ W/bit (typ)
- Single 5V supply voltage ($\pm 10\%$ tolerance)
- Requires neither external clock nor refreshing
- All inputs and outputs are directly TTL compatible
- All outputs are three-state, with OR-tie capability
- Easy memory expansion by chip-select (\overline{CS}) input
- Common data I/O terminals
- Interchangeable with Intel's 2114L and TI's TMS4045 in pin configuration and electrical characteristics

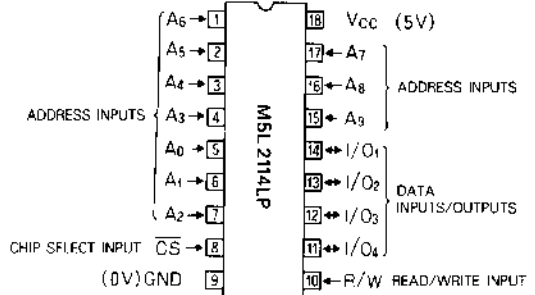

APPLICATION

- Small-capacity memory units

FUNCTION

These devices operate with a single 5V power supply, and the inputs and outputs are directly compatible with TTL. All circuits are completely static, rendering external clock and refresh operations unnecessary, and making the members of the series extremely easy to use. Common data input and output terminals are provided.

PIN CONFIGURATION (TOP VIEW)

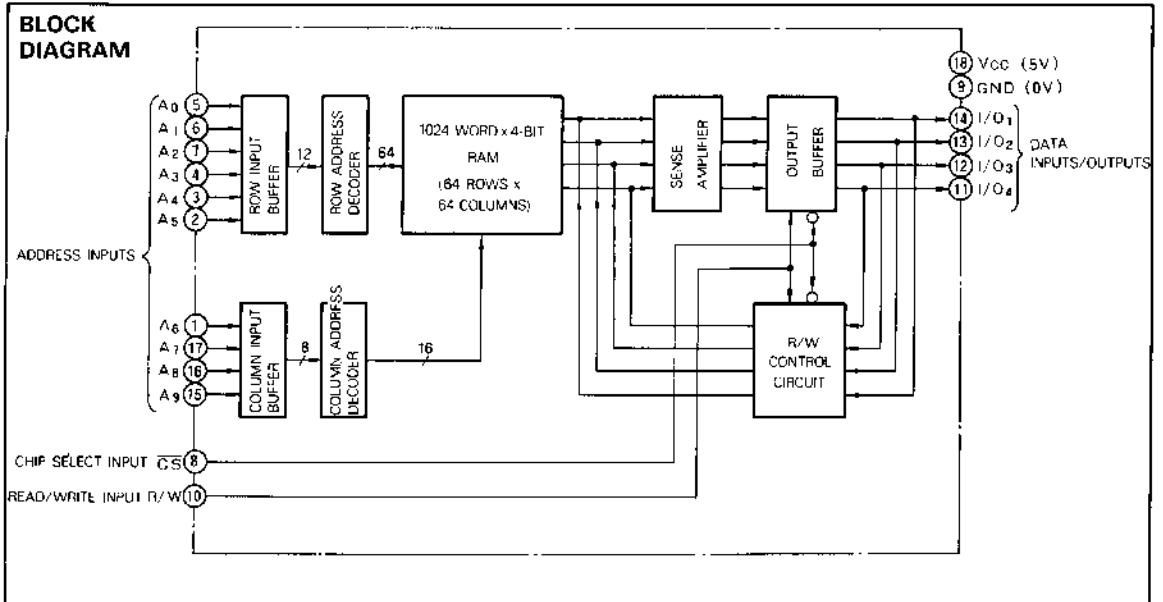

Outline 18P4

During a write cycle, when a location is designated by address signals $A_0 \sim A_9$, and the R/W signal goes low, the data at the I/O terminals is written.

During a read cycle, when the R/W signal goes high and a location is designated by address signals $A_0 \sim A_9$, the data of the designated address is available at the I/O terminals.

When signal \overline{CS} is high, the chip is in the non-selectable state, disabling both reading and writing. In this case the data outputs are in the floating (high-impedance) state, useful for OR-ties with the output terminals of other chips.

BLOCK DIAGRAM

4096-BIT (1024-WORD BY 4-BIT) STATIC RAM

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage		-0.5~7	V

TYPICAL CHARACTERISTICS

APPLICATION EXAMPLE (for an M5L 8080A P CPU)

1024-BIT (256-WORD BY 4-BIT) CMOS STATIC RAM

DESCRIPTION

This is a 256-word by 4-bit static RAM fabricated with the silicon-gate CMOS process and designed for low power dissipation and easy application of battery back-up.

The device has two chip-select inputs \overline{CS}_1 and CS_2 . While maintained in the chip non-select state, the device consumes power at the low value of only $10\mu A$ (max) standby current and accordingly is especially suitable as a memory system for battery-operated applications and for battery back-up.

The device operates on a single 5V supply, as does TTL, and inputs and outputs are directly TTL-compatible and are provided with common I/O terminals.

FEATURES

- Access time: 450ns (max)
- Low power dissipation in the standby mode: $10\mu A$ (max)
- Single 5V power supply
- Data holding at 2V supply voltage
- No external clock or refreshing operation required
- Both inputs and outputs are directly TTL-compatible
- Outputs are three-state, with OR-tie capability
- Simple memory expansion by chip-select signals
- Input and output data terminals are separate
- Interchangeable with Intel's 5101L-1 in pin configuration and electrical characteristics

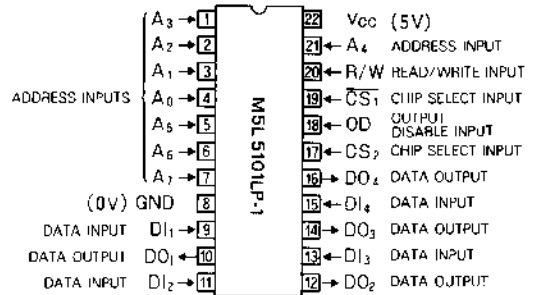

APPLICATION

- Battery-driven or battery back-up small-capacity memory units

FUNCTION

The device provides separate data input and output terminals.

PIN CONFIGURATION (TOP VIEW)

Outline 22P1

During a write cycle, when a location is designated by address signals $A_0 \sim A_7$ and signal R/W goes low, the data of the DI inputs at that time is written.

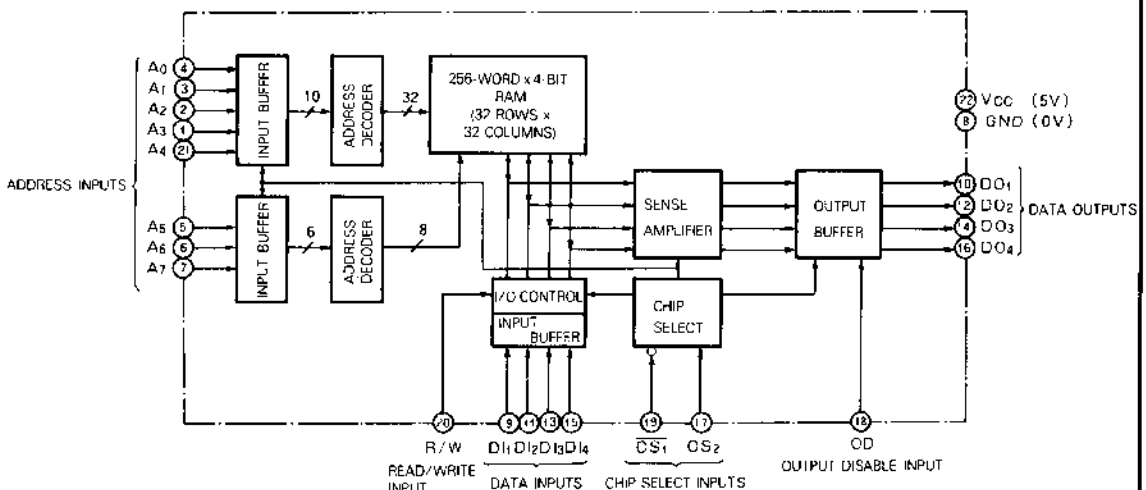

During a read cycle, when a location is designated by address signals $A_0 \sim A_7$, and signal R/W goes high, the data of the designated address is available at the DO terminals.

When signal \overline{CS}_1 is high or CS_2 is low, the chip is in the non-selectable state, disabling both reading and writing. In this case, the output is in the floating (high-impedance state) useful for OR-ties with the output terminals of other chips.

When the signal OD is high, the output is in the floating state, so that OD is used as an input/output select control signal for common input/output operation.

The memory data can be held at a supply voltage of 2V, enabling battery back-up operation during power failure and power-down operation in the standby mode.

M5T 4044 P-20, P-30, P-45

4096-BIT (4096-WORD BY 1-BIT) STATIC RAM

DESCRIPTION

This is a family of 4096-word by 1-bit static RAMs, fabricated with the N-channel silicon-gate MOS process and designed for simple interfacing. They operate with a single 5V supply, as does TTL, and are directly TTL-compatible.

FEATURES

Parameter	M5T 4044P-20	M5T 4044P-30	M5T 4044P-45
Access time (max)	200ns	300ns	450ns
Cycle time (min)	200ns	300ns	450ns

- Low power dissipation: 50 μ w/bit (typ)
- Single 5V supply ($\pm 10\%$ tolerance)
- Requires no clocks or refreshing
- All inputs and outputs are directly TTL-compatible
- All outputs are three-state and have OR-tie capability
- Simple memory expansion by chip-select (\overline{CS}) input
- Interchangeable with T1's TMS4044 in pin configuration and electrical characteristics

APPLICATION

- Small-capacity memory units

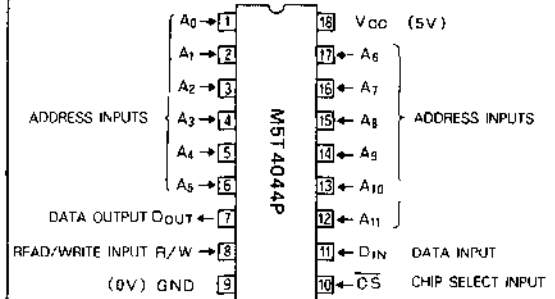

FUNCTION

These devices are very convenient to use, as they feature static circuits which require neither external clocks nor refreshing, and all inputs and outputs are directly compatible with TTL.

During a write cycle, when a location is designated by address signals $A_0 \sim A_{11}$ and the R/W signal goes low, the D_{IN} signal data at that time is written.

During a read cycle, when the R/W signal goes high

PIN CONFIGURATION (TOP VIEW)

Outline 18P4

and a location is designated by address signals $A_0 \sim A_{11}$, the data of the designated address is available at the D_{OUT} terminals.

When signal \overline{CS} is high, the chip is in the non-selectable state, disabling both reading and writing. In this case the output is in the floating (high-impedance) state, useful for OR-ties with other output terminals.

DEVELOPMENT OF MASK-PROGRAMMABLE ROMs

GENERAL INFORMATION

This information explains how to specify the object program for the automatic design system for mask ROMs. This system for mask ROM production has been developed to accept a customer's specifications in a number of forms and media.

The main segments of the automatic design system are:

1. The plotter instructions for mask production.
2. A check list for verifying that the customer's specifications have been met.
3. A test program to assure that the production ROMs meet specifications.

When loading an object program into masked ROM, the object program is provided at the time of ordering in the form of EPROM memory. The EPROM device or devices are sent with the required verification sheets, three devices of each type.

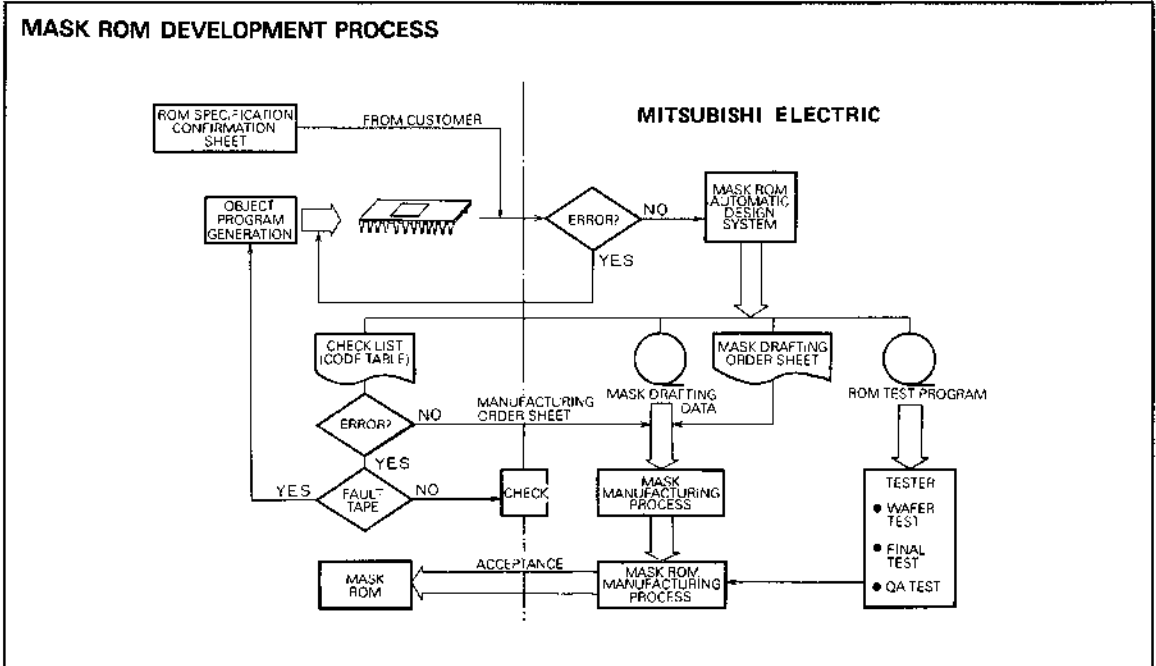

EPROM SPECIFICATIONS

1. Mitsubishi M5L2708K, M5L2716K, M5L5732K and Intel 2708, 2716, or 2764 or equivalent EPROMs may be used. The standard for ordering is, however, Mitsubishi M5L2708K, M5L2716K and M5L2732K EPROM.
2. EPROM data and addresses should be programmed with the high logic level as a logic 1.
3. The EPROM data should include all valid data from the starting address to the last address to be programmed.

3

ITEMS TO BE VERIFIED

1. Specify the type number as M58333-XXXX, M58735-XXXX, or M58334-XXXX (the three digits after the hyphen of the type number is a code to indicate the customer contents and is assigned by Mitsubishi).
2. Mark the EPROM device tops with the EPROM type and the address specification symbols A,B,C, or D. The addresses indicated by these symbols are listed on the ROM verification sheets.

**1024-BIT (256-WORD BY 4-BIT) FIELD-PROGRAMMABLE ROM
 WITH OPEN COLLECTOR OUTPUTS**

DESCRIPTION

The memory cells of the M54700P,S are a 256-word by 4-bit matrix of diodes and Ni-Cr fuse links. Data can be electrically programmed by open-circuiting fuses in the field with simple programming equipment. These 1024-bit field-programmable ROMs (PROMs) are composed of an address decoder, memory, output and chip enable TTL circuits.

FEATURES

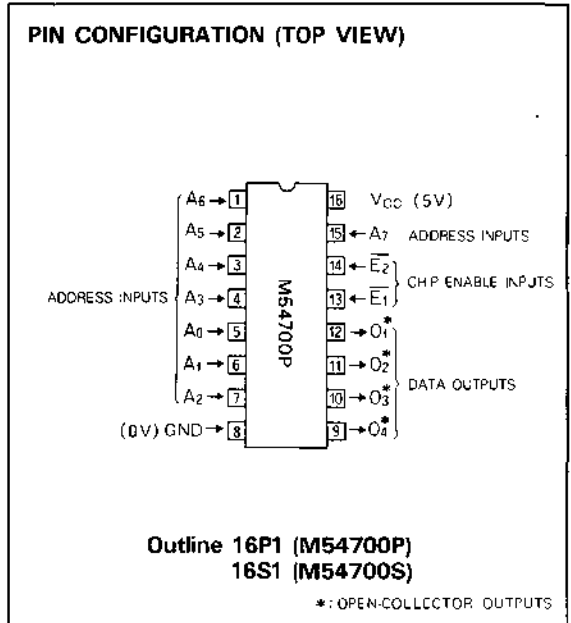

- Field-programmable ROM
- Low power dissipation: 0.40mW/bit
- Fast access time: 50ns (typ)
- 5V±5% single supply voltage
- Inputs and outputs TTL-compatible
- Open collector outputs
- Two chip enable inputs (\overline{E}_1 , \overline{E}_2) for easy memory expansion
- Organized as 256 words of 4 bits
- 16-pin ceramic or plastic package
- Interchangeable with MMI's 6300 in pin configuration and electrical characteristics

APPLICATION

- Programmable memory for the M5L8080A 8-bit parallel CPU. Used for prototype design, microprogramming and control storage.

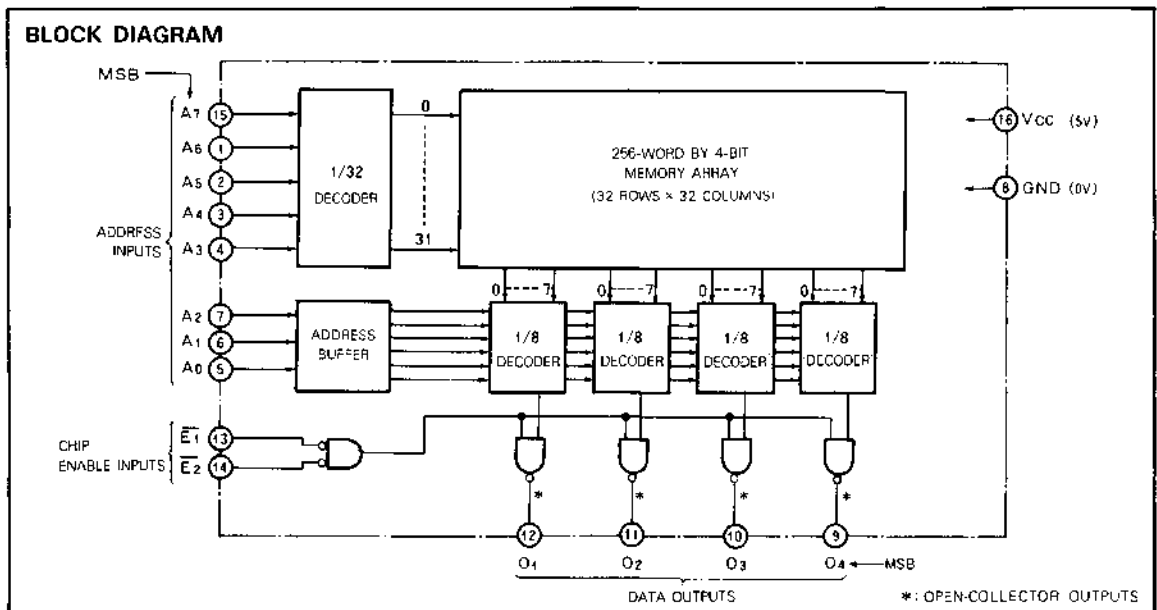

FUNCTION

This device is accessed by address inputs $A_0 \sim A_7$, selecting one of 256 words. The 4-bits are read out in parallel on data outputs $O_1 \sim O_4$. All inputs are TTL-compatible. An

3

external decoder is not necessary. All outputs are open-collector outputs, so it is possible to AND-tie them to other ROMs and TTL devices. The AND-tie fanout of each output can accommodate up to 10 standard TTL loads. The chip enables \overline{E}_1 and \overline{E}_2 are used to inhibit data outputs $O_1 \sim O_4$.

Programming Circuit

5. After programming is completed, apply an additional three programming pulses.

6. Test the programmed memory to verify that the outputs are low-level or high-level as desired. Both chip enable inputs \bar{E}_1 and \bar{E}_2 must be low-level for testing.

The word decoder circuit selects any one of 32 columns, and sets the transistor Tr_2 to the on state. The bit decoder circuit selects any four of 32 rows, and supplies the base current to transistor Tr_1 from chip enable input \bar{E}_1 .

The fuse link is opened not by the base current, but by the collector current which is supplied to transistor Tr_1 from the selected output $O_1 \sim O_4$, plus the base current. At this time, the other three fuse links of the selected word line are in a half-selected stage and the remaining 1020 fuse links are in a non-selected state.

Programming (Writing) Procedure

All 1024 Ni-Cr fuse-link memory elements are manufactured in a high-logic-level (fuse closed) output condition. To program:

1. Apply 5.5V to the supply voltage V_{CC} and select a fuse link to be programmed with address inputs $A_0 \sim A_7$.
2. Apply a high-logic-level to the chip enable input \bar{E}_2 .
3. After applying a program pulse $V_{I(CEP)}$ to the chip enable input \bar{E}_1 (see Timing Diagrams), apply an output pulse $V_{O(P)}$ to the fuse link of the output to be programmed. The output pulses should be separately applied to each output.
4. After programming, the fuse link is open and the output level is changed to a low-logic-level.

Typical Programming Conditions

Condition sequence	Pulse sequence	Pulse width $t_w(P)$ (ms)	Chip enable program voltage $V_{I(CEP)}$ (V)	Output voltage (V)
1	1 ~ 4	0.5	29	25
2	5 ~ 8	1	29	25
3	9 ~ 12	5	30	25
4	13 ~ 19	20	33	25

**1024-BIT (256-WORD BY 4-BIT) FIELD-PROGRAMMABLE ROM
WITH OPEN COLLECTOR OUTPUTS**

APPLICATIONS

Chip Enable Circuit

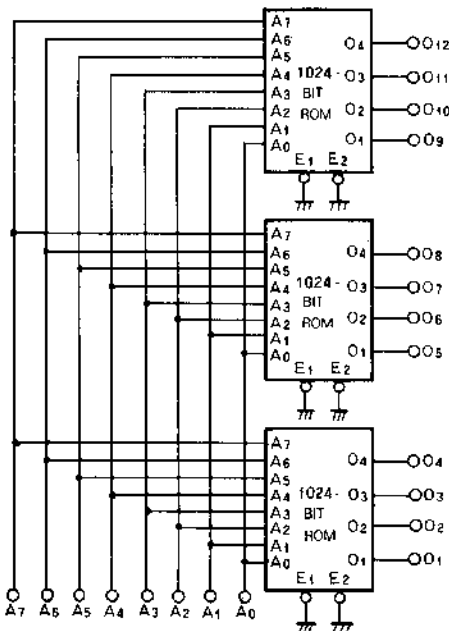

The chip enable inputs \overline{E}_1 and \overline{E}_2 are used for activating or inhibiting output $O_1 \sim O_4$. \overline{E}_1 and \overline{E}_2 are NORred. Output is inhibited when any of the inputs are high-logic-level. Chip enable inputs \overline{E}_1 and \overline{E}_2 allow easy memory expansion by one of the following procedures:

1. Expanding the Number of Bits in a Word

For example, using three 1024-bit ROMs, each organized as 256 words of 4 bits, the number of bits in a word can be expanded as described below:

1. Apply a low-logic-level to both chip enable inputs \overline{E}_1 and \overline{E}_2 of each ROM.
2. Connect address inputs $A_0 \sim A_7$ of each ROM in parallel. Memory is thus expanded and reorganized as 256 words of 12 bits.

Fig. 1 Expansion of number of bits

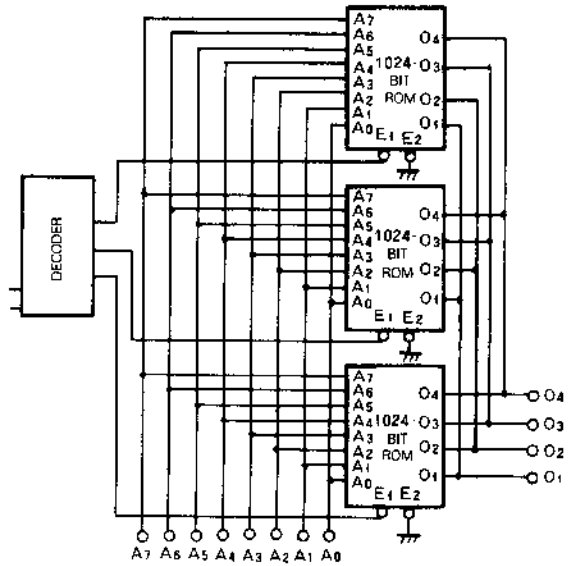

2. Expanding the Number of Words in Memory

For example, using three 1024-bit ROMs, each organized as 256 words of 4 bits, the number of words in memory can be expanded as described below:

1. Connect one of the chip enable inputs \overline{E}_1 or \overline{E}_2 of each ROM to the decoder while keeping the remaining input at low-logic-level.
2. Connect the outputs from each ROM with AND-tie connections so that each output is an open-collector output circuit or a three-state output. Memory is thus expanded and organized as 768 words of 4 bits.

Fig. 2 Expansion of number of words

3. Expanding the Number of Words in Memory and the Number of Bits in a Word

For example, using nine 1024-bit ROMs, each organized as 256 words of 4 bits, and by combining procedures 1 and 2 above, the number of words in memory along with the number of bits in a word, can be expanded as described below:

1. The chip enable input \overline{E}_2 of all ROMs is connected in parallel for module selection.
2. The chip enable input \overline{E}_1 activates selected ROMs the same as 2 above.

Memory is thus expanded and reorganized as 768 words of 12 bits.

1024-BIT (256-WORD BY 4-BIT) FIELD-PROGRAMMABLE ROM
WITH OPEN COLLECTOR OUTPUTS

Fig. 3 ROM module

Pull-up Resistors

The outputs are open collectors; therefore, AND-tie connections are also possible, and normal loads can be connected. The resistance of a pull-up resistor R_L that may be connected between the voltage supply and the collectors of the output transistors should be determined by equations (1) and (2) as shown below:

$$R_L(\max) = \frac{\overline{V_{CC}} - \underline{V_{OH}}}{M \cdot \overline{I_{OH}} + N \cdot \overline{I_{IH}}} \quad \dots \dots \dots (1)$$

- where, M : number of AND-ties
- N : number of fanouts (number of loads)
- $\overline{V_{CC}}$: maximum value of supply voltage
- $\underline{V_{OH}}$: minimum value of high-level output voltage
- $\overline{I_{OH}}$: maximum value of high-level output current at the open collector output
- $\overline{I_{IH}}$: maximum value of high-level input current

$$R_L(\min) = \frac{\overline{V_{CC}} - \underline{V_{OL}}}{\overline{I_{OL}} - N \cdot \overline{I_{IL}}} \quad \dots \dots \dots (2)$$

- where, $\overline{V_{CC}}$: minimum value of supply voltage
- $\underline{V_{OL}}$: maximum value of low-level output voltage
- $\overline{I_{OL}}$: maximum value of low-level output current
- $\overline{I_{IL}}$: maximum value of low-level input current

then,

$$R_L(\min) < R_L < R_L(\max) \quad \dots \dots \dots (3)$$

The resistance of a pull-up resistor R_L should be within the range as shown in equation (3). $R_L(\min)$ and $R_L(\max)$ should be calculated using the appropriate number of AND-ties and fanouts. Calculation examples of TTL load are shown below:

(1) When

$$M = 4, N = 3, \overline{V_{CC}} = 5.25V, \underline{V_{OH}} = 2.4V, \overline{I_{OH}} = 100\mu A, \overline{I_{IH}} = 40\mu A$$

$$R_L(\max) = \frac{\overline{V_{CC}} - \underline{V_{OH}}}{M \cdot \overline{I_{OH}} + N \cdot \overline{I_{IH}}} = \frac{5.25V - 2.4V}{4 \times (100\mu A) + 3 \times (40\mu A)} = 5090\Omega$$

(2) When

$$N = 3, \underline{V_{CC}} = 4.75V, \underline{V_{OL}} = 0.45V, \overline{I_{OL}} = 16mA, \overline{I_{IL}} = 1.6mA$$

$$R_L(\min) = \frac{\overline{V_{CC}} - \underline{V_{OL}}}{\overline{I_{OL}} - N \cdot \overline{I_{IL}}} = \frac{4.75V - 0.45V}{16mA - 3 \times (1.6mA)} = 384\Omega$$

**256-BIT (32-WORD BY 8-BIT) FIELD-PROGRAMMABLE ROM
 WITH OPEN COLLECTOR OUTPUTS**

DESCRIPTION

The memory cells of the M54730P, S are a 32-word by 8-bit matrix of diodes and Ni-Cr fuse links. Data can be electrically programmed by open-circuiting fuses in the field with simple programming equipment. These 256-bit field programmable ROMs (PROMs) are composed of an address decoder, memory, output and chip enable TTL circuits.

FEATURES

- Field programmable ROM
- Low power dissipation: 1.5mW/bit
- Fast access time: 45ns (typ)
- 5V±5% single supply voltage
- Inputs and outputs TTL-compatible
- Open-collector outputs
- Chip enable inputs (\bar{E}) for easy memory expansion
- Organized as 32 words of 8 bits
- 16-pin ceramic or plastic package
- Interchangeable with MMI's 6300 in pin configuration and electrical characteristics

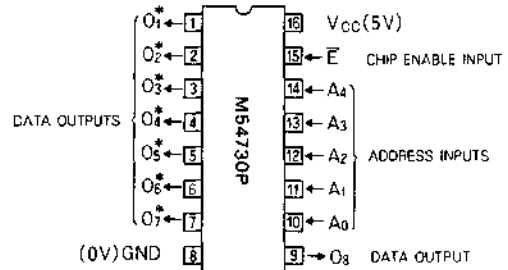

APPLICATION

- Programmable memory for the M5L 8080A 8-bit parallel CPU. Used for prototype design, microprogramming and control storage.

FUNCTION

This device is accessed by address inputs $A_0 \sim A_4$, selecting one of 32 words. The 8 bits are read out in parallel on data outputs $O_1 \sim O_8$. All inputs are TTL-compatible. An external

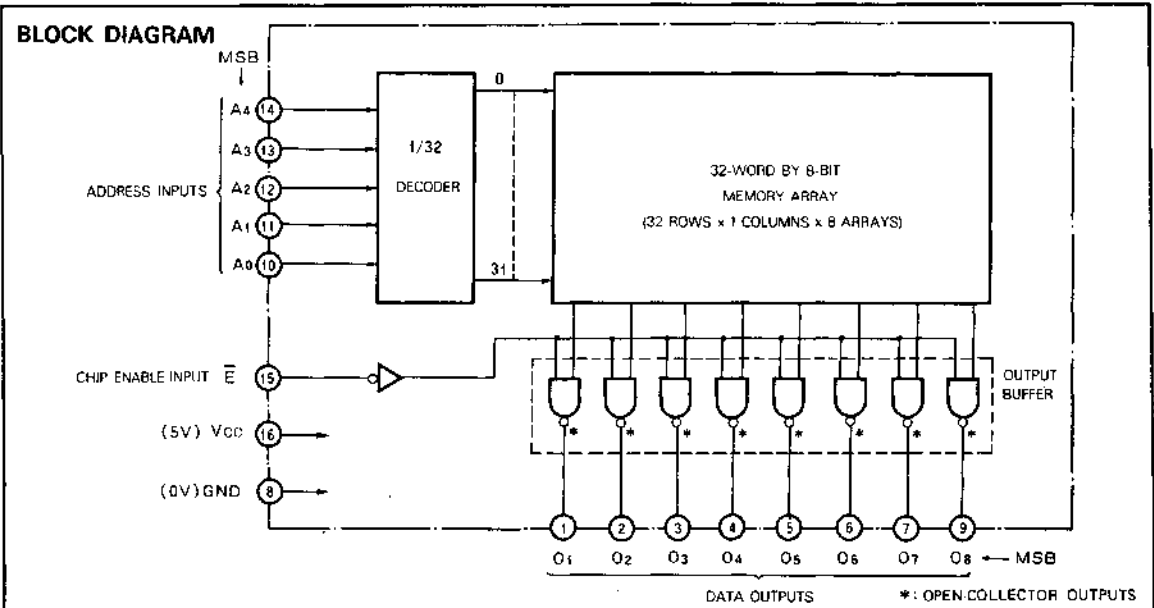

PIN CONFIGURATION (TOP VIEW)

Timing Diagram

Programming Circuit

Programming (Writing) Procedure

All 256 Ni-Cr fuse-link memory elements are manufactured in a high-logic-level (fuse closed) output condition. To program:

1. Apply 5.5V to the supply voltage V_{CC} and select a fuse link to be programmed with address inputs $A_0 \sim A_4$.
2. Apply a high-logic-level to the chip enable input \bar{E} .
3. After applying a program pulse $V_{I(CEP)}$ to the chip enable input \bar{E} (see Timing Diagram), apply an output pulse $V_{O(P)}$ to the fuse link of the output to be programmed. The output pulses should be separately applied to each output.
4. After programming, the fuse link is open and the output level is changed to a low-logic-level.
5. After programming is completed, apply an additional three programming pulses.

6. Test the programmed memory to verify that the outputs are low-level or high-level as desired. Chip enable input \bar{E} must be low-level for testing.

As the chip enable input \bar{E} is kept high-level during programming, transistor Tr_1 maintains the off state. The word decoder circuit selects any one of 32 words, and sets the transistor Tr_1 to the on state. The collector current of the transistor Tr_2 , which is supplied from the selected output O_1 , opens the fuse links. At this time, the other seven fuse links of the selected word line are in a half-selected state and the other 248 fuse links are in a nonselected state.

Typical Programming Conditions

Condition sequence	Pulse sequence	Pulse width $t_w(P)$ (ms)	Chip enable program voltage $V_{I(CEP)}$ (V)	Output voltage (V)
1	1 ~ 4	0.5	29	25
2	5 ~ 8	1	29	25
3	9 ~ 12	5	30	25
4	13 ~ 19	20	33	25

256-BIT (32-WORD BY 8-BIT) FIELD-PROGRAMMABLE ROM
WITH OPEN COLLECTOR OUTPUTS

APPLICATIONS

Chip Enable Circuit

The chip enable input \bar{E} is used for activating or inhibiting output $O_1 \sim O_8$. Chip enable \bar{E} allows easy memory expansion by one of the following procedures:

1. Expanding the Number of Bits in a Word

For example, using three 256-bit ROMs, each organized as 32 words of 8 bits, the number of bits in a word can be expanded as described below:

1. Apply a low-logic-level to chip enable input \bar{E} of each ROM.
2. Connect address inputs $A_0 \sim A_4$ of each ROM in parallel. Memory is thus expanded and reorganized as 32 words of 24 bits.

2. Expanding the Number of Words in Memory

For example, using three 256-bit ROMs, each organized as 32 words of 8 bits, the number of words in memory can be expanded as described below:

1. Connect the chip enable input \bar{E} of each ROM to the decoder.
2. Connect the outputs from each ROM with AND-tie connections.
3. Connect each address input $A_0 \sim A_4$ commonly. Memory is thus expanded and organized as 96 words of 4 bits.

3. Expanding the Number of Words in Memory and the Number of Bits in a Word

For example, using nine 256-bit ROMs, each organized as 32 words of 8 bits, and by combining procedures 1 and 2 above, the number of words in memory along with the number of bits in a word, can be expanded as shown in the diagram below.

Memory is thus expanded and reorganized as 96 words of 24 bits.

Pull-up Resistors

The outputs are open collectors; therefore, AND-tie connections are also possible, and normal loads can be

connected. The resistance of a pull-up resistor R_L that may be connected between the voltage supply and the collectors of the output transistors should be determined by equations (1) and (2) as shown below:

$$R_L(\max) = \frac{V_{CC} - V_{OH}}{M \cdot I_{OH} + N \cdot I_{IH}} \quad \dots \dots \dots (1)$$

- where M : number of AND-ties
 N : number of fanouts (number of loads)
 V_{CC} : maximum value of supply voltage
 V_{OH} : minimum value of high-level output voltage
 I_{OH} : maximum value of high-level output current at the open collector output
 I_{IH} : maximum value of high-level input current

$$R_L(\min) = \frac{V_{CC} - V_{OL}}{I_{OL} - N \cdot I_{IL}} \quad \dots \dots \dots (2)$$

- where V_{CC} : minimum value of supply voltage
 V_{OL} : maximum value of low-level output voltage
 I_{OL} : maximum value of low-level output current
 I_{IL} : maximum value of low-level input current

then

$$R_L(\min) < R_L < R_L(\max) \quad \dots \dots \dots (3)$$

The resistance of a pull-up resistor R_L should be within the range as shown in equation (3). $R_L(\min)$ and $R_L(\max)$ should be calculated using the appropriate number of AND-ties and fanouts. Calculation examples of TTL load are shown below:

(1) When

- $M = 4, N = 3, V_{CC} = 5.25V,$
 $V_{OH} = 2.4V, I_{OH} = 100\mu A,$
 $I_{IH} = 40\mu A$

$$R_L(\max) = \frac{V_{CC} - V_{OH}}{M \cdot I_{OH} + N \cdot I_{IH}} = \frac{5.25V - 2.4V}{4 \times (100\mu A) + 3 \times (40\mu A)} = 5090\Omega$$

(2) When

- $N = 3, V_{CC} = 4.75V,$
 $V_{OL} = 0.45V, I_{OL} = 16mA,$
 $I_{IL} = 1.6mA$

$$R_L(\min) = \frac{V_{CC} - V_{OL}}{I_{OL} - N \cdot I_{IL}} = \frac{4.75V - 0.45V}{16mA - 3 \times (1.6mA)} = 384\Omega$$

MITSUBISHI BIPOLAR DIGITAL ICs

M54740AP,S/M54741AP,S

4096-BIT(1024-WORD BY 4-BIT)FIELD PROGRAMMABLE ROM

DESCRIPTION

The M54740AP,S (provided with open collector outputs) and the M54741AP, S (provided with 3-state outputs) are field programmable ROMs with a fusecoupling system and a memory capacity of 4096 bits (1024 words x 4-bit configuration).

FEATURES

- Fast address access time.....25ns (typ)
- Unique built-in test circuit guarantees a high programming yield as well as various performance characteristics after programming
- Fuse technology is used
- Memory capacity of 4096 bits (1024 words x 4-bit organization)
- Open collector outputs for M54740AP,S;
3-state outputs for M54741AP,S
- High output level before programming
- Chip enable pins \bar{E}_1 and \bar{E}_2 provided for easy expansion of memory capacity
- Inputs and outputs compatible with TTL system
- 18-pin DIL ceramic or plastic package

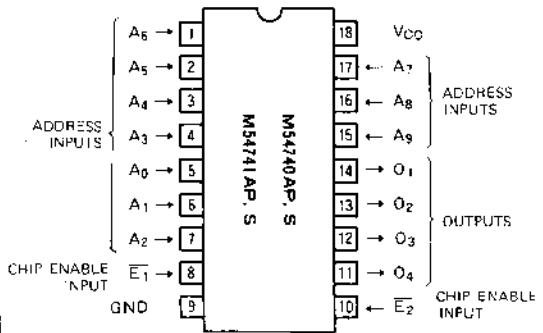

APPLICATION

General purpose, for use in industrial and consumer equipment.

FUNCTIONAL DESCRIPTION

The PROM consists of an address circuit, decoder circuit, memory circuit, output circuit and chip enable circuit, and the memory cells consist of fuses and diodes. Data can be programmed into the PROM by the user using a writer

PIN CONFIGURATION (TOP VIEW)

Outline 18S1 (M54740AS, M54741AS)
18P4 (M54740AP, M54741AP)

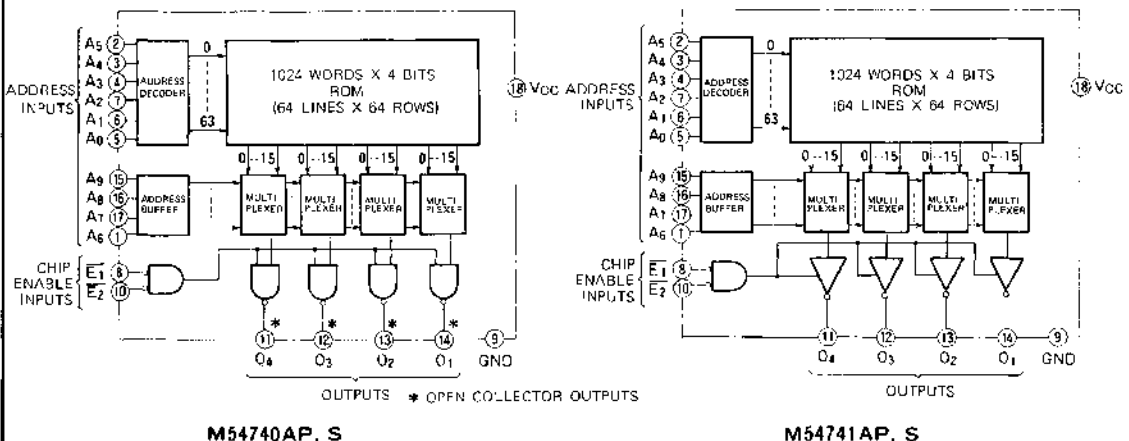

by cutting the fuses of the memory cells. The output level is high before programming and low when written into.

The 4096 memory cells have a capacity of 1024 words and one word is composed of 4 bits. A word is selected from the 1024 words by address inputs $A_0 \sim A_9$, and 4-bit parallel outputs $O_1 \sim O_4$ are produced.

The input and output threshold voltage is the same as that for a TTL system and thus direct coupling can be made with TTL logic. The open-collector outputs (in the M54740AP,S) or 3-state outputs (in the M54741AP,S) enable AND-tie connection.

When both chips enable inputs \bar{E}_1 and \bar{E}_2 are low, the output is enabled and the contents of the memory selected

C_{OUT}	Output capacitance	$V_{CC} = 5\text{V}, V_O = 2\text{V}, f = 1\text{MHz}$		7		pF

* All typical values are at $V_{CC}=5\text{V}, T_A=25^\circ\text{C}$.

Note 2: All measurements should be done quickly and not more than one output should be shorted at a time.

Note 3: I_{CC} is measured with all inputs at GND.

$V_{CC}(P)$	Write supply voltage		5		V
I_{OP}	Applied output current			100	mA
$V_{CCL}(V)$	Low-level supply voltage with check after writing		4.4		V

4096-BIT(1024-WORD BY 4-BIT)FIELD PROGRAMMABLE ROM

PROGRAMMING TIMING DIAGRAM

Note 5. The $V_{O(P)}$ waveform is the voltage waveform applied to the output during programming; the $O_1 \sim O_4$ waveforms indicate the output level of the device itself.
 Note 6. Waveform \bar{E} indicates either the \bar{E}_1 or \bar{E}_2 waveform; the other is $V_{IL(P)}$.

PROGRAMMING PROCEDURE

The area into which the data are programmed is the fuses which are composed of 4096 memory cells. When no data are programmed into a memory cell, the output is set to the logic high level (fuse: closed). Proceed as instructed below to set to the logic low level (fuse: open).

- (1) Apply the supply voltage $V_{CC(P)}$ (5V typ).
- (2) Select the programming word with the address inputs $A_0 \sim A_9$ (input voltage: $V_{IH(P)}$ 5V typ, $V_{IL(P)}$ 0V typ).
- (3) Set either chip enable input pin \bar{E}_1 or \bar{E}_2 high ($V_{IH(P)}$ 5V typ) and set the outputs off.
- (4) Apply the output pulse $V_{O(P)}$ (21V typ) to the output which corresponds to the bit into which the data are to be programmed. Apply this to one output at a time and not to two or more outputs simultaneously.
- (5) Set both \bar{E}_1 and \bar{E}_2 low ($V_{IL(P)}$ 0V typ).
- (6) Reduce the supply voltage to $V_{CCL(V)}$ (4.4V typ) and check whether the data has been programmed.
- (7) If the check is affirmative in step (6), repeat steps (1) through (6) to program the next word or bit.

If the check is negative in step (6), repeat steps (1) through (6) but if the check is still negative even after four repetitions, the device may be considered defective.

Refer to the programming timing diagram for the timing of the programming operation.

700-BIT (50-WORD BY 14-BIT) ELECTRICALLY ALTERABLE ROM

DESCRIPTION

The M58653P is a serial input/output 700 bit electrically erasable and reprogrammable ROM organized as 50 words of 14 bits, and fabricated using MNOS technology. Data and addresses are transferred serially via a one-bit bidirectional bus.

FEATURES

- Word-by-word electrically alterable
- Non-volatile data storage: 10 years (min)
- Write/erase time: 20ms/word
- Typical power supply voltages: -30V, +5V
- Number of erase-write cycles: 10⁵ times (min)
- Number of read access unrefreshed: 10⁹ times (min)
- 5V I/O interface

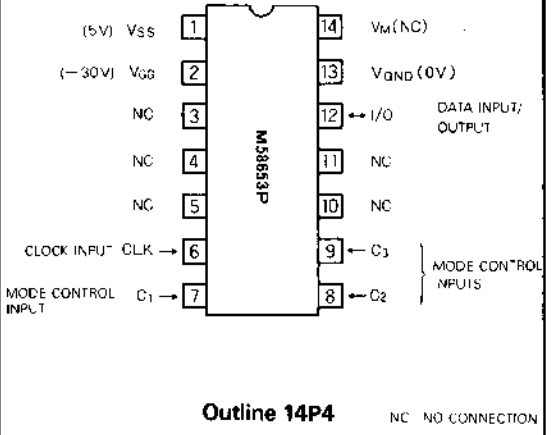

APPLICATION

- Non-volatile channel memories for electronic tuning systems and field-reprogrammable read-only memory systems

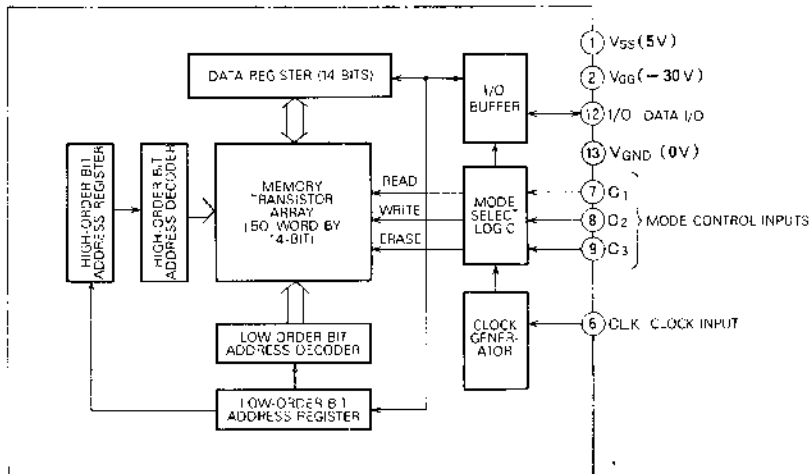

FUNCTION

The address is designated by two consecutive one-of-ten-coded digits. Seven modes—accept address, accept data, shift data output, erase, write, read, and standby—are all selected by a 3-bit code applied to C₁, C₂, and C₃. Data is stored by internal negative writing pulses that selectively tunnel charges into the SiO₂-Si₃N₄ interface of the gate insulators of the MNOS memory transistors.

PIN CONFIGURATION (TOP VIEW)

BLOCK DIAGRAM

700-BIT (50-WORD BY 14-BIT) ELECTRICALLY ALTERABLE ROM

PIN DESCRIPTION

Pin	Name	Functions
I/O	I/O	In the accept address and accept data modes, used for input. In the shift data output mode, used for output. In the standby, read, erase and write modes, this pin is in a floating state.
V _W	Test	Used for testing purposes only. It should be left unconnected during normal operation.
V _{SS}	Chip substrate voltage	Normally connected to +5V.
V _{DD}	Power supply voltage	Normally connected to -30V.
CLK	Clock input	14kHz timing reference. Required for all operating modes. High-level inputs possible during standby mode.
C ₁ - C ₃	Mode control input	Used to select the operation mode.
V _{GND}	Ground voltage	Connected to ground (0V).

3

OPERATION MODES

C ₁	C ₂	C ₃	Functions
H	H	H	Standby mode. The contents of the address registers and the data register remain unchanged. The output buffer is held in the floating state.
H	H	L	Not used.
H	L	H	Erase mode. The word stored at the addressed location is erased. The data bits after erasing are all low-level.
H	L	L	Accept address mode. Data presented at the I/O pin is shifted into the address registers one bit with each clock pulse. The address is designated by two one-of-ten-coded digits.
L	H	H	Read mode. The addressed word is read from the memory into the data register.
L	H	L	Shift data output mode. The output driver is enabled and the contents of the data register are shifted to the I/O pin one bit with each clock pulse.
L	L	H	Write mode. The data contained in the data register is written into the location designated by the address registers.
L	L	L	Accept data mode. The data register accepts serial data from the I/O pin one bit with each clock pulse. The address registers remain unchanged.

MITSUBISHI LSI's
M58735-XXXP

32768-BIT(4096-WORD BY 8-BIT) MASK-PROGRAMMABLE ROM

DESCRIPTION

The M58735-XXXP is a 32768-bit static mask-programmable read-only memory organized as 4096 words of eight bits. It is housed in a 24-pin DIL package using N-channel silicon gate MOS technology. The inputs and outputs are TTL compatible.

The XXX in the type code is a three-digit decimal number assigned by Mitsubishi to identify the customer's specification to which the ROM has been programmed.

FEATURES

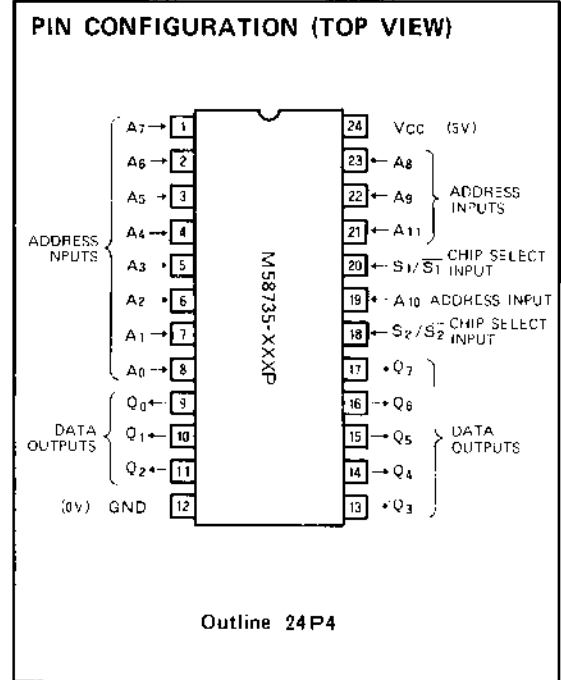

- Maximum access time: 350ns (max)
- 8-bit parallel output
- By floating the output (high-impedance) using the chip select inputs (S_1 , S_2), OR-tie connection is possible, facilitating memory expansion.
- The active logic level of the chip select inputs (S_1 and S_2) can be programmed at the time of ROM masking
- All inputs and outputs are TTL and DTL compatible
- All inputs are provided with built-in protective circuits
- Pin-compatibility with the M5L2732K

APPLICATION

- Microcomputer memories

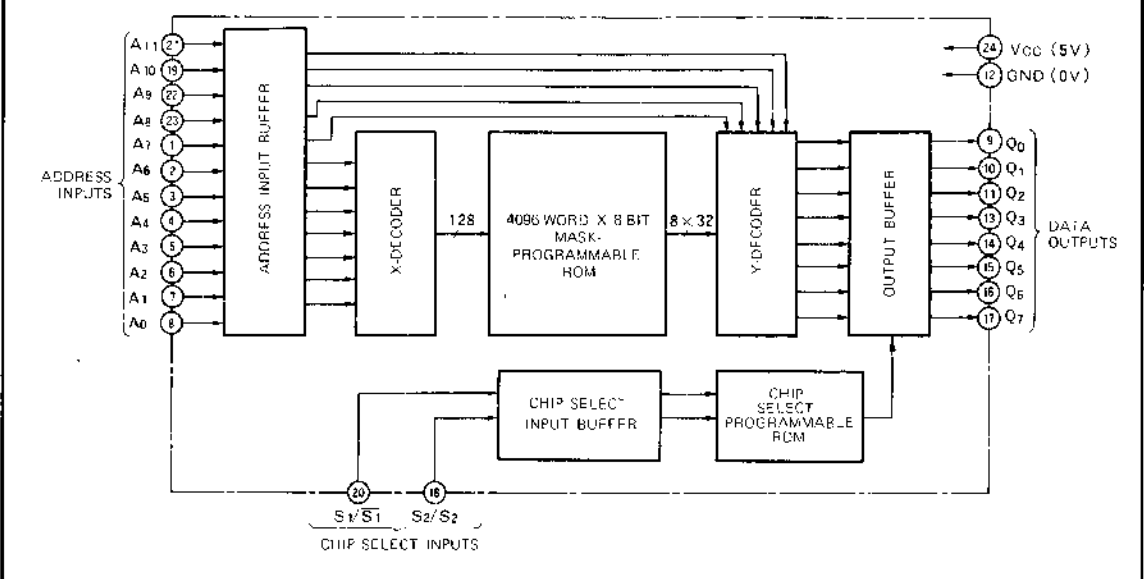

FUNCTION

The M58735-XXXP is a 4096 x 8-bit parallel output ROM. Address inputs ($A_0 \sim A_{11}$) are decoded to select one of the 4096 words, and the contents of that address are made available at data outputs ($Q_0 \sim Q_7$). Chip selects (S_1 and S_2) are used to expand memory using two or more M58735-XXXP ROMs. The contents of the ROM

can be read only when S_1 and S_2 are at the programmed input levels. Otherwise, data outputs ($Q_0 \sim Q_7$) are held in the floating (high-impedance) state. The active logic level of S_1 and S_2 can be programmed at the time of fabricating the ROM mask.

1400-BIT (100-WORD BY 14-BIT) ELECTRICALLY ALTERABLE ROM

DESCRIPTION

The M5G1400P is a serial input/output 1400-bit electrically erasable and reprogrammable ROM organized as 100 words of 14 bits, and fabricated using MNOS technology. Data and addresses are transferred serially via a one-bit bidirectional bus.

FEATURES

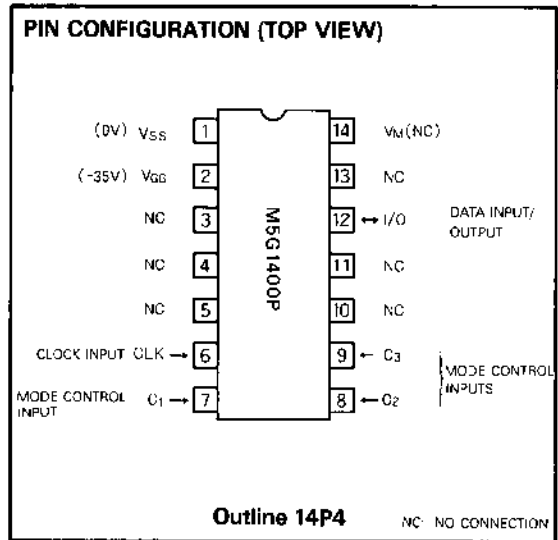

- Word-by-word electrically alterable
- Non-volatile data storage: 10 years (min)
- Write/erase time: 20ms/word
- Single 35V power supply
- Number of erase-write cycles: 10^5 times (min)
- Number of read access unrefreshed: 10^6 times (min)
- Interchangeable with GI's ER1400 in pin configuration and electrical characteristics

APPLICATION

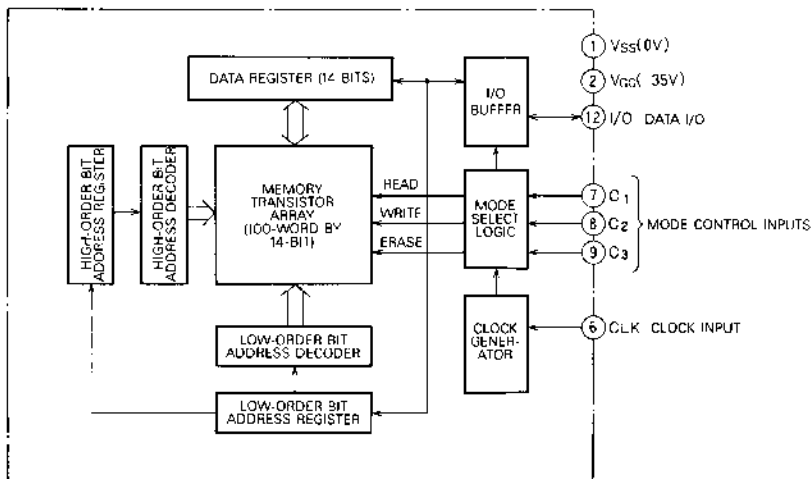

- Non-volatile channel memories for electronic tuning systems and field-reprogrammable read-only memory systems

FUNCTION

The address is designated by two consecutive one-of-ten-coded digits. Seven modes—accept address, accept data, shift data output, erase, write, read, and standby—are all selected by a 3-bit code applied to C₁, C₂, and C₃. Data is stored by internal negative writing pulses that selectively tunnel charges into the SiO₂-Si₃N₄ interface of the gate insulators of the MNOS memory transistors.

MITSUBISHI LSIs M5L 2716 K, K-65

**16 384-BIT (2048-WORD BY 8-BIT)
ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM**

DESCRIPTION

These are ultraviolet-light erasable and electrically re-programmable 16 384-bit (2048-word by 8-bit) EPROMs. They incorporate N-channel silicon-gate MOS technology, and are designed for microprocessor programming applications.

FEATURES

- Fast programming : 100s/16 384 bits (typ)
- Access time M5L2716K : 450ns (max)
M5L2716K-65 : 650ns (max)
- Static circuits are used throughout
- Inputs and outputs TTL-compatible in read and program modes
- Single 5V power supply for read mode
(25V power supply required for program)
- Low power dissipation: Operating : 525mW (max)
Standby : 132mW (max)
- Single-location programming
(requires one 50ms pulse/address)
- Interchangeable with Intel's 2716 in pin configuration and electrical characteristics

APPLICATION

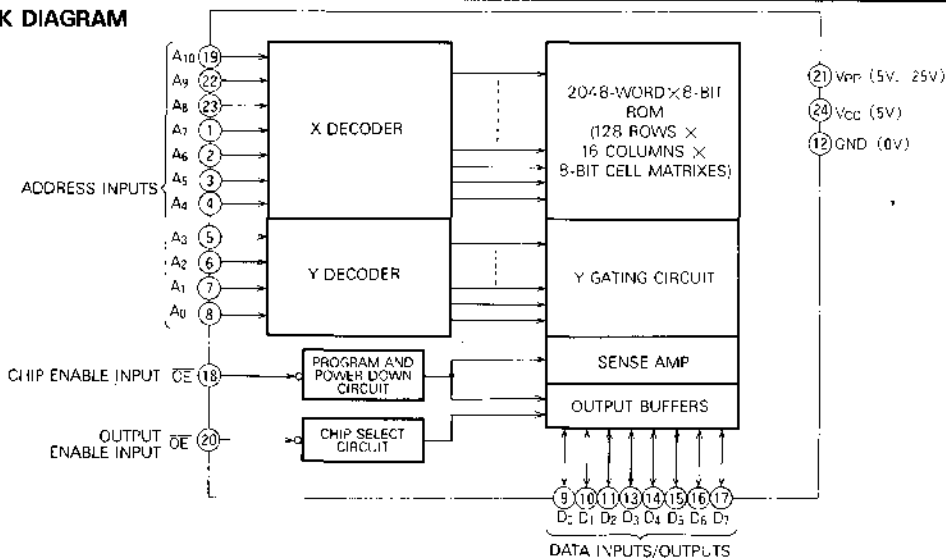

- Computers and peripheral equipment

PIN CONFIGURATION (TOP VIEW)

Outline 24K10

BLOCK DIAGRAM

**16 384-BIT (2048-WORD BY 8-BIT)
 ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM**

FUNCTION

Read

Set the \overline{CE} and \overline{OE} terminals to the read mode (low-level). Low-level input to \overline{CE} and \overline{OE} and address signals to the address inputs ($A_0 \sim A_{10}$) make the data contents of the designated address location available at the data inputs/outputs ($D_0 \sim D_7$). When the \overline{CE} or \overline{OE} signal is high, data inputs/outputs ($D_0 \sim D_7$) are in a floating state.

When the \overline{CE} signal is high, the device is in the standby mode or power-down mode.

Programming

The chip enters the programming mode when 25V is supplied to the V_{PP} power supply input and \overline{OE} is at high-level. A location is designated by address signals $A_0 \sim A_{10}$, and the data to be programmed must be applied at 8 bits in parallel to the data inputs $D_0 \sim D_7$. A program pulse to the \overline{CE} at this state will effect programming. Only one programming pulse is required, but its width must satisfy the condition $45\text{ms} \leq t_{W(\overline{CE})} \leq 55\text{ms}$.

Mode selection

(Unit: V)

Mode	Pin	\overline{CE}	\overline{OE}	V_{PP}	V_{CC}	Outputs
Read		V_{IL}	V_{IL}	5	5	Output
Deselect		$V_{IL} \sim V_{IH}$	V_{IH}	5	5	Floating
Power down		V_{IH}	$V_{IL} \sim V_{IH}$	5	5	Floating
Program		Pulsed V_{IL} to V_{IH}	V_{IH}	25	5	Input
Program verify		V_{IL}	V_{IL}	5 or 25	5	Output
Program inhibit		V_{IL}	V_{IH}	25	5	Floating

ABSOLUTE MAXIMUM RATING

Symbol	Parameter	Conditions	Limits	Unit
V_{I1}	Input voltage, V_{PP}	With respect to GND	-0.3 - 26.5	V
V_{I2}	Input voltage, V_{CC} , address, \overline{OE} , \overline{CE} , data		0.3 - 6	V
T_{opr}	Operating free-air temperature range		0 - 70	°C
T_{stg}	Storage temperature range		-65 - 125	°C

READ OPERATION

Recommended Operating Conditions ($T_a = 0 \sim 70^\circ\text{C}$, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V_{CC}	Supply voltage	4.75	5	5.25	V
V_{PP}	Supply voltage	($V_{PP} - V_{CC}$)			V
GND	Supply voltage		0		V
V_{IL}	Low-level input voltage	0.1		0.8	V
V_{IH}	High-level input voltage	2.2		$V_{CC} + 1$	V

Erase

Erase is effected by exposure to ultraviolet light with a wavelength of 2537Å at an intensity of approximately 15Ws/cm².

PRECAUTIONS FOR READ OPERATION

- V_{CC} should be turned on with or before V_{PP} and turned off with or after V_{PP} .
- V_{PP} should be connected directly to V_{CC} except during programming. For supply current design, therefore, V_{PP} and V_{CC} should be added.

HANDLING PRECAUTIONS

- Sunlight and fluorescent light may contain ultraviolet light sufficient to erase the programmed information. For any operation in the read mode, the transparent window should be covered with opaque tape.
- High voltages are used when programming, and the conditions under which it is performed must be carefully controlled to prevent the application of excessively high voltages. Specifically, the voltage applied to V_{PP} should be kept below 26V including overshoot. Special precautions should be taken at the time of power-on.
- Before erasing, clean the surface of the transparent lid to remove completely oily impurities or paste, which may impede irradiation and affect the erasing characteristics.

**32 768-BIT(4096-WORD BY 8-BIT)
 ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM**

DESCRIPTION

These are ultraviolet-light erasable and electrically reprogrammable 32 768-bit (4096-word by 8-bit) EPROMS. They incorporate N-channel silicon-gate MOS technology, and are designed for microprocessor programming applications.

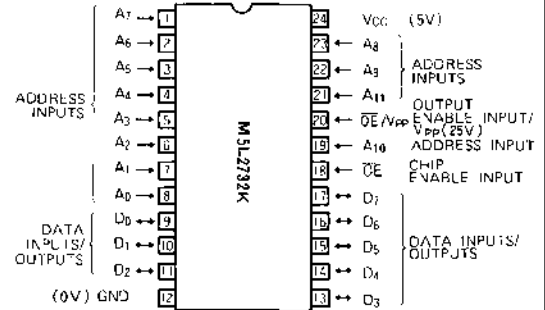

FEATURES

- Fast programming: 200s/32 768 bits (typ)
- Access time M5L 2732K: 450ns (max)
 M5L 2732K-6: 550ns (max)
- Static circuits are used throughout
- Inputs and outputs TTL-compatible in read and program modes
- Single 5V power supply for read mode
 (25V power supply required for program)
- Low power dissipation: Operating: 787mW (max)
 Standby: 157mW (max)
- Single-location programming
 (requires one 50ms pulse/address)
- Interchangeable with Intel's 2732 in pin configuration

APPLICATION

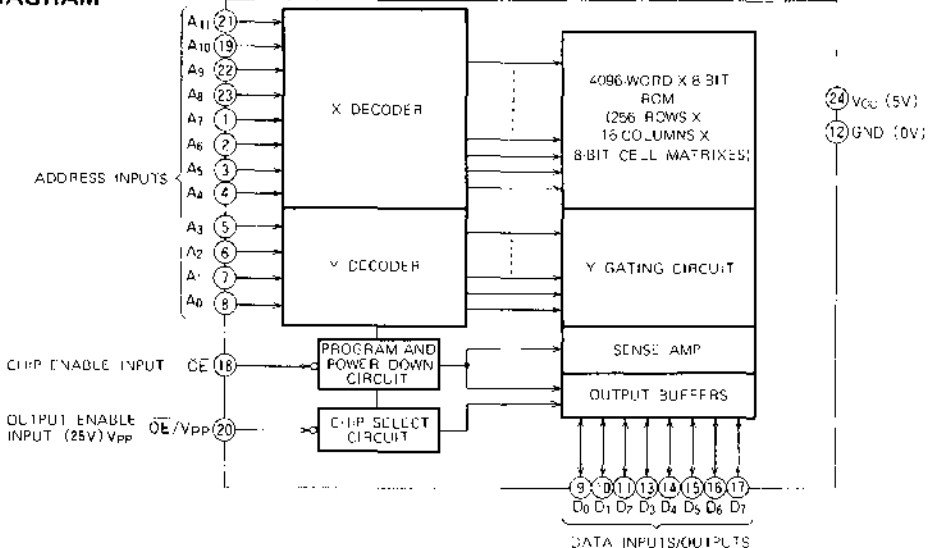

- Computers and peripheral equipment

PIN CONFIGURATION (TOP VIEW)

Outline 24K10

BLOCK DIAGRAM

**32 768-BIT(4096-WORD BY 8-BIT)
 ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM**

FUNCTION

Read

Set the \overline{CE} and \overline{OE} terminals to the read mode (low-level). Low-level input to \overline{CE} and \overline{OE} and address signals to the address inputs ($A_0 \sim A_{11}$) make the data contents of the designated address location available at the data inputs/outputs ($D_0 \sim D_7$). When the \overline{CE} or \overline{OE} signal is high, data inputs/outputs ($D_0 \sim D_7$) are in a floating state.

When the \overline{CE} signal is high, the device is in the standby mode or power-down mode.

Programming

The chip enters the programming mode when 25V is supplied to the \overline{OE}/V_{PP} input. A location is designated by address signals $A_0 \sim A_{11}$, and the data to be programmed must be applied at 8 bits in parallel to the data inputs $D_0 \sim D_7$. A program pulse, an active low pulse, to the \overline{CE} at this state will effect the programming operation. Only one programming is required, but its width must satisfy the condition $45ms \leq t_{W(CE)} \leq 55ms$.

Erase

Erase is effected by exposure to ultraviolet light with a wavelength of 2537\AA at an intensity of approximately $15W/cm^2$.

HANDLING PRECAUTIONS

1. Sunlight and fluorescent light may contain ultraviolet light sufficient to erase the programmed information. For any operation in the read mode, the transparent window should be covered with opaque tape.
2. High voltages are used when programming, and the conditions under which is it performed must be carefully controlled to prevent the application of excessively high voltages. Specifically, the voltage applied to V_{PP} should be kept below 26V including overshoot. Special precautions should be taken at the time of power-on.
3. Before erasing, clean the surface of the transparent lid to remove completely oily impurities or paste, which may impede irradiation and affect the erasing characteristics.

**65536-BIT (8192-WORD BY 8-BIT)
ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM**

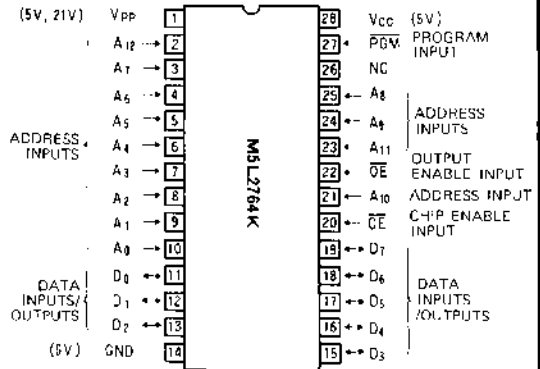

DESCRIPTION

The Mitsubishi M5L2764K is a high-speed 65536-bit ultraviolet erasable and electrically reprogrammable read only memory. It is suitable for microprocessor programming applications where rapid turn-around is required. The M5L2764K is fabricated by N-channel double polysilicon gate technology and is available in a 28-pin DIL package with a transparent lid.

FEATURES

- 8192 Word x 8-bit Organization
- Access Time
 - M5L2764K-2 200 ns (Max)
 - M5L2764K 250 ns (Max)
 - M5L2764K-3 300 ns (Max)
- Two Line Control \overline{OE} , \overline{CE}
- Low Power Current (I_{CC}) Active 150 mA (Max)
Standby . . . 35 mA (Max)
- Single 5V Power Supply
- 3-State Output Buffer
- Input and Output TTL-Compatible in Read and Program Mode
- Standard 28-pin DIL Package
- Single Location Programming with One 50 ms Pulse
- Interchangeable with INTEL 2764

BLOCK DIAGRAM

M5L2764K, K-2, K-3

65536-BIT (8192-WORD BY 8-BIT) ERASABLE AND ELECTRICALLY REPROGRAMMABLE ROM

FUNCTION

Read

Set the \overline{CE} and \overline{OE} terminals to the read mode (low level).

Low level input to \overline{CE} and \overline{OE} and address signals to the address inputs ($A_0 \sim A_{12}$) make the data contents of the designated address location available at the data input/output ($D_0 \sim D_7$). When the \overline{CE} or \overline{OE} signal is high, data input/output are in a floating state.

When the \overline{CE} signal is high, the device is in the standby mode or power-down mode.

Programming

The device enters the programming mode when 21V is supplied to the V_{PP} power supply input and \overline{CE} is at low

level. A location is designated by address signals ($A_0 \sim A_{12}$), and the data to be programmed must be applied at 8-bits in parallel to the data inputs ($D_0 \sim D_7$). A program pulse to the PGM at this state will effect programming. Only one programming pulse is required, but its width must satisfy the condition $45 \text{ ms} \leq t_{ew} \leq 55 \text{ ms}$.

Erase

Erase is effected by exposure to ultraviolet light with a wavelength of 2537Å at an intensity of approximately 15 WS/cm². Sunlight and fluorescent light may contain ultraviolet light sufficient to erase the programmed information. For any operation in the read mode, the transparent lid should be covered with opaque tape.

MELPS4MICROCOMPUTERS

4

MITSUBISHI MICROCOMPUTER

M58840-XXXP, M58841-XXXP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

DESCRIPTION

The M58840-XXXP and M58841-XXXP are single chip 4-bit microcomputers developed using p-channel aluminum gate ED-MOS technology and are housed in 42-pin plastic DIL packages. These single-chip microcomputers feature a built-in 8-bit A-D converter.

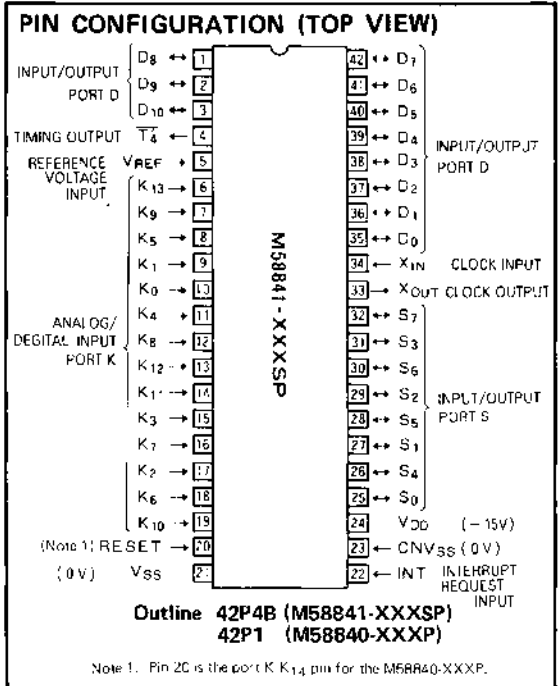

Differences between the M58840-XXXP and M58841-XXXP.

M58840-XXXP	Pin 5 is used as both the V _{REF} input and RESET input.
M58841-XXXP	The V _{REF} input pin and RESET input pin are separate, with pin 20 being used as the RESET input. Therefore, port K is a 14-bit port.

Except for the above differences, unless otherwise noted, the M58840-XXXP is the same as the M58841-XXXP.

FEATURES

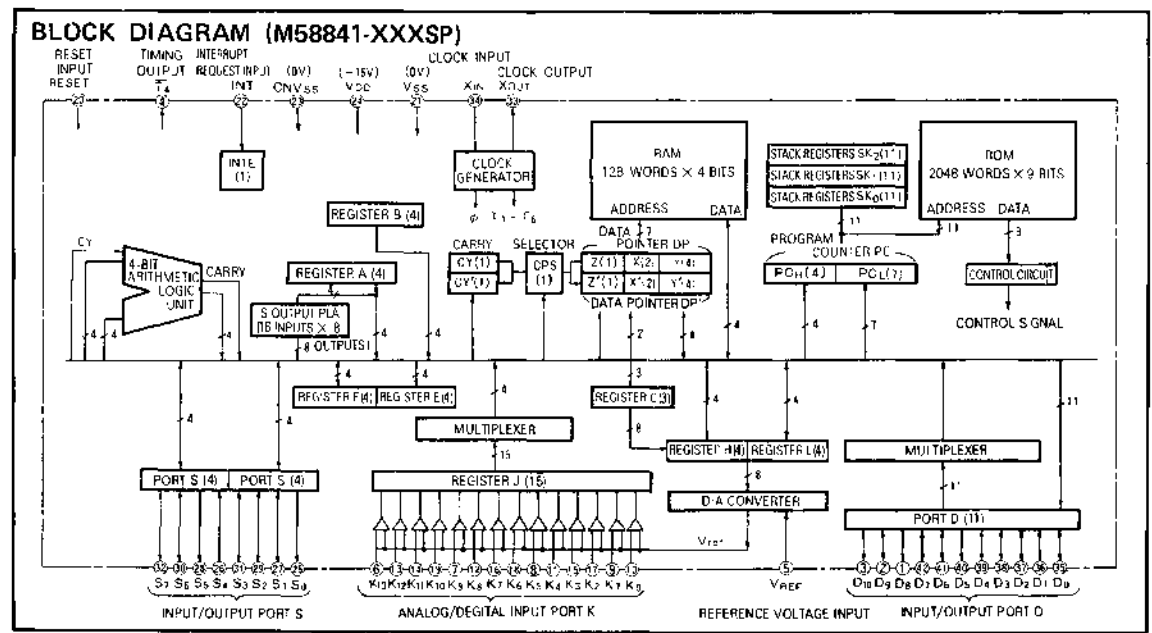

- Basic machine instructions 68
- Basic instruction execution time (1-word instruction at a clock frequency of 600kHz) 10μs
- Memory capacity: ROM 2048 words × 9 bits
RAM 128 words × 4 bits
- Single -15V power supply
- Built-in A/D converter (14 or 15 analog inputs)
- 2 built-in data pointers
- Analog/digital input (port K):
M58840-XXXP 15 inputs
M58841-XXXP 14 inputs
- Input/output port (ports D and S) 19 lines
- Direct drive for large fluorescent display tubes is possible
- Interrupt function 1 factor 1 level

- Built-in decoder PLA for port S output (mask option)
- On-chip clock generator

APPLICATIONS

- Microwave ovens, air conditioners, heaters, washing machines, home sewing machines
- Office equipment, copying machines, medical equipment

Power dissipation (excluding ports)		400 mW (typ)	400 mW (typ)

PIN DESCRIPTION

Pin	Name	Input or output	Function
VDD VSS	Power supplies	In	VDD and VSS are applied as $\pm 15V \pm 10\%$ and 0V respectively.
K0 K13	Input port K	In	The input port K consists of 14 (15 for the M58840-XXXP) independent analog input pins. They can be programmed to receive digital quantities as well.
S0 S7	Input/output port S	In/out	The I/O port S can be used as either an 8-bit output port or a pair of 4-bit input ports. Since it has open drain circuits, it is suitable for directly driving segments of a large fluorescent display tube. When the output port S is programmed to a low level, it remains in the floating state (high-impedance) so that it can be used as an input port.
D0 D10	Input/output port D	In/out	The I/O port D is composed of 11 bits that can be used as independent I/O bits. When the port D outputs are programmed to a low level, the output remains in the floating state (high-impedance) and the input signal level is sensed.
XIN	Clock input	In	A clock generator is built into the device so that the clock frequency is determined by connecting an external RC circuit or ceramic resonator between pins XIN and XOUT. When an external clock source is used, it should be connected to the XIN pin, leaving the XOUT pin open.
XOUT	Clock output	Out	This pin is the output of the built-in clock generator circuit. The oscillation frequency is controlled by connecting an RC circuit or ceramic resonator element between this pin and the XIN pin.
INT	Interrupt request input	In	This pin is used to input the interrupt request signal. The level of the interrupt signal can be programmed as either high or low.
T _A	Timing output	Out	This is the basic timing output. It is used for testing and should be connected to VSS (0V).
VREF	Reference voltage input	In	This is the input for the reference voltage applied to the D-A converter. For the M58840-XXXP it serves as the RESET input pin as well.
GVSS	GVSS input	In	This input is connected to VSS and must have a high-level input applied to it (0V).
RESET	Reset input	In	This is the reset input pin for the M58841-XXSP. The reset state is enabled when it is kept high for at least two machine cycles.

MITSUBISHI MICROCOMPUTER M58840-XXXP, M58841-XXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

BASIC FUNCTION BLOCKS

Program Memory (ROM)

This 2048-word x 9-bit mask programmable ROM can be programmed with machine instruction codes in accordance with the customer's specifications. It consists of 16 pages, each containing an address range of 0 ~ 127. Fig. 1 shows the address map of this ROM.

Program Counter (PC)

This counter is used to specify ROM addresses and the sequence of read-out of instructions stored in ROM. The program counter (PC) is an 11-bit counter, the upper order 4 bits of each (PC_H) indicate the ROM page, and the lower order 7 bits (PC_L) of which are a pure binary address designation. Each time an instruction is executed, PC_L is incremented by one step. For branching, subroutine call instructions and return instructions, its value is set to the designated address.

When the 127th address is reached for every page, the address value returns to the first address of that page. Therefore, for moving from one page to another page, the page byte itself must be modified. This is done using the BL and BLA instructions.

Page 14 and page 15 are special pages used for subroutine calls. The page 14 subroutine can be called with a one word instruction from any arbitrary page. This instruction is either BM or BMA. When either BM or BMA is executed, subsequent BM or BMA instructions are equivalent to B and BA on page 14. Also, B or BA is equivalent to B or BA on page 15. This condition is cancelled when the RT, RTS, BL, BML, BLA or BMLA instruction is executed. Table 3 shows the instruction codes and corresponding states.

Stack Registers (SK₀, SK₁, SK₂)

These registers are used to temporarily store the contents of the PC while executing subroutines or interrupt programs until the program returns to its main routine. The SK registers are organized in three words of 11 bits each, enabling up to three levels of subroutine nesting. If one level is used for an interrupt routine, the remaining two levels can be used for subroutine calls.

Data Memory (RAM)

This 512-bit (128 words x 4 bits) RAM is used to store both processing and control data. One RAM word consists of 4 bits with bit manipulation possible over the entire storage area. The 128 words are arranged as 2 file groups x 4 files x 16 digits x 4 bits. Fig. 2 shows the RAM address map.

The RAM address specification is made by the combination of data pointer DP (register Z, register X and register

Y.) Thus, the selector CPS and data pointer DP must be set. However, as long as the address is not changed this is not necessary.

Data Pointers (DP, DP')

These registers are used to designate RAM address, and bit positions for the I/O port D and register J. Each data pointer is composed of a 7-bit register. Register Z (the most significant bit of DP) designates the RAM file group; register X (the central 2 bits) designates a RAM file; and register Y (the least significant 4 bits) designates the digit position of the RAM file. At the same time, register Y designates bit positions of the I/O port D and register J.

4-bit Arithmetic Logic Unit (ALU)

This unit executes 4-bit arithmetic and logical operations by means of a 4-bit adder and related logic circuitry. The arithmetic logic unit performs subtraction, addition, logical comparisons, arithmetic comparisons, and bit manipulation.

Register A and Carry flag (CY)

Register A is a 4-bit accumulator that constitutes the basis for arithmetic operations. Data processing operations such as arithmetic and logical operations, data transfer, exchange, conversion and data input/output are executed by means of this register. Overflow of register A is stored in the carry flag's CY or CY' after execution of arithmetic or logical operations. The carry flags can also be used as 1-bit flags. Carry flags and data pointer DP selection is done by means of the selector CPS.

15																				

Fig. 2 RAM Address map

Registers B and E

Register B is composed of 4 bits and can be used as a 4-bit temporary storage register or for 8-bit data transfer in conjunction with register A. Register E is composed of 8 bits and is used not only as an 8-bit temporary storage register, but also as a temporary storage register for I/O port S.

A/D Conversion Circuit

The following A/D conversion functions are controlled by software as described below. Fig. 3 shows the block diagram.

(1) Comparators

These comparators are implemented entirely with PMOS devices and use a chopper-type amplification method. They are capable of determining the difference of the D/A converter output V_{ref} and the port K input signals $V_{K(Y)}$ (where $Y=0\sim 13$).

(2) Register J

Register J is composed of 14 1-bit registers, each representing the comparison result from the comparators. All register bits are set simultaneously. The value of the register J with respect to the comparison results is as follows.

$$1 \text{ when } |V_{ref}| > |V_{K(Y)}|$$

$$0 \text{ when } |V_{ref}| < |V_{K(Y)}|$$

In this relationship(Y) represents the bit position in register J which is designated by register Y. The comparison results can be checked for each bit using the SZJ instruction.

(3) Registers H and L

These two 4-bit registers are capable of transferring and exchanging data to and from register A. The 8-bit digital data for the D-A converter is transferred from these registers, the higher order 4 bits from H and lower order 4 bits from L.

(4) Register C

This 3-bit register is used as a counter to designate bit positions in the H and L registers.

(5) D/A Converter

The D/A converter converts the digital values stored in the registers H and L, referencing with the external reference voltage V_{REF} applied at the pin V_{REF} , to the analog value of the internal reference voltage V_{ref} . The theoretical value of the internal reference voltage V_{ref} is defined as follows.

$$V_{ref} = \frac{n - 0.5}{256} \times V_{REF}$$

where $n = 1, 2, \dots, 255$

$$V_{ref} = 0 \text{ where } n = 0$$

In the above relationships n is the value weighted accorded to the contents of registers H and L.

A/D Conversion Algorithms

A/D conversion is controlled by the programming of the previously described functional blocks. Thus, by modifying the program either the successive approximation method or the sequential comparison method may be selected. In addition, a digital input of high or low level may be used to select the method, eliminating software selection of the A/D conversion technique.

(1) Successive Approximation Method

In this method, a constant conversion speed is maintained regardless of the amplitude of the analog signal. The A/D conversion process requires 0.6ms (at 600kHz clock frequency). 12 program words are required.

(2) Sequential Comparison Method

In this method the conversion speed varies in accordance with the rate of change of the analog quantity. When the rate of change is slow, the conversion rate increases. 30 program words are required.

Fig. 3 A/D Conversion circuit block diagram

Interrupt Function

The flag INTE is a 1-bit flip-flop used to control interrupt operation. When an interrupt request signal is applied to the pin INT while the interrupt is enabled, the INTE flag is reset to disable further interrupts, after which the program jumps from the main program to address 0 of page 12. When an interrupt program is used, one level of the three-level stack register is required, the remaining two levels being used for subroutines. After the interrupt program is started, the data pointer DP, register A, carry flag CY, and registers used by the interrupt program must be saved and these must be restored before returning to the main program. The returning may be done by the execution of RTI instruction.

When an interrupt occurs, the microcomputer internal states are as follows.

(1) Program Counter

The current address in the main program is stored in a stack register and the program counter is set to page 12, address 0.

MITSUBISHI MICROCOMPUTER
M58840-XXXP, M58841-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH 8-BIT A/D CONVERTER

(2) Interrupt Flag INTE

The flag INTE is reset to disable further interrupts. This disabled state will continue even after the program has returned from the interrupt routine to the main program by the execution of the RTI instruction. EI is executed and when the input level of the INT input changes, this state is disabled. Thus, when the INT instruction is executed the interrupt state is enabled when the INT input goes high. As long as it remains in the high state, further interrupts are prohibited. If the INT input should change to a low level and return to high, the next interrupt will be accepted.

(3) Skip Flags

Skip flags are provided for skip instructions and consecutively described instructions and these skip flags discriminate the skip and non skip conditions. Each flag has its own stack within which the skip state is saved.

As a mask option, the interrupt pin may be provided with Schmitt input circuits.

Input/Output Pins

(1) Input port K

The input port K consists of 14 pins (15 pins for the M58840-XXXP). The voltage level input at these pins is compared with the D-A converter output voltage Vref by a comparator and the results stored in register J. As a mask option, it is possible to build into the input port K load resistors. These are implemented using an enhancement-type (M58840-XXXP) or depletion-type (M58841-XXXSP) MOS transistors. In addition, to enable the use of capacitive touch-type keys, it is possible to provide these inputs with the required discharge transistors.

(2) Input/Output Port S

The input/output port S consists of 8 bits, each bit with an output latch. These latches are used to store data transferred by means of a PLA from register A, or data transferred from register A or register B directly. 4 bits at a time of the 8 input bits of port S may be transferred to register A.

Because port S outputs are provided with a built-in PLA, it is possible to output any arbitrarily settable 8-bit code from 4 input bits specified by register A. These PLA output codes can be specified arbitrarily as a masked option.

(3) Input/Output Port D

The input/output port D consists of 11 bits. Each bit can be individually designated as either input or output and is provided with its own latch. The contents of the data pointer register Y can be used to designate a single bit of port D for output or sensing.

When port S or port D is used as an input port, the output should first be cleared to the low state.

Reset Function

For the M58840-XXXP, when a power source satisfying the conditions shown in Fig. 4 is applied, an internal power-on reset function operates to reset the microcomputer. Cancelling of the reset state also is performed automatically, the program being started at page 0, address 0.

If the power-on reset function does not operate properly because of the trailing edge characteristics of the power supply, reset can be enabled by inputting a high level at the VREF pin. Setting this VREF pin to low starts the program at page 0, address 0.

For the M58841-XXXSP, if the RESET input is kept high for at least two machine cycles, the reset state is enabled. Because the M58841-XXXSP is provided with an internal charging transistor it requires only an external diode and capacitor as shown in Fig. 5.

For this configuration, when the supply voltage falls below -13.5V, the circuit design should ensure that the RESET input is above -4V.

When the reset state is enabled, the following operations are performed.

- (1) The program counter is set to page 0, address 0
 $(PC) \leftarrow 0$
 - (2) The interrupt mode is in the interrupt disabled state
 $(INTE) \leftarrow 0$
- This is the same state as when the instruction DI is executed.
- (3) By setting the interrupt request signal INT to high, the interrupt enabled state is entered. This is the same state as when the instruction INTH is executed.
 - (4) All outputs of port S are cleared to low $(S) \leftarrow 0$
 - (5) All outputs of port D are cleared to low $(D) \leftarrow 0$
 - (6) The carry and data pointer selector CPS is cleared to low to designate DP and CY $(CPS) \leftarrow 0$

Clock Generator Circuit

A clock generator circuit has been built-in to the M58840-XXXP and M58841-XXXSP, allowing control of the frequency by means of an externally connected RC circuit or ceramic resonator. In addition, an external clock signal may be applied at the X_{IN} pin, leaving the X_{OUT} pin open. Circuit examples are shown in Fig. 6 to Fig. 8.

MACHINE INSTRUCTIONS

Type of instruction	Mnemonic	Instruction code				16 bit notation	Skip conditions	No. of cycles	Functions	Skip conditions	Flag CY	Description of operation		
		D ₇	D ₆	D ₅	D ₄									
RAM addresses	LXY X,Y	0	1	x	y	0	CY	1	(X)←x, where, x=0-3 (Y)←y, where, y=0-15	Written successively	X	Loads value of "x" into register X, and of "y" into Y. When LXY is written successively, the first is executed and successive ones are skipped		
	LZ z	0	0	1	0	1	0	4	(Z)←z, where, z=0,1		X	Loads value of "z" into register Z		
	INY	0	0	0	0	0	0	0	2	(Y)←(Y)+1	(Y)=0	X	Increments contents of register Y by 1. Skips next instruction when new contents of register Y are "0".	
	DEY	0	0	0	0	0	0	0	3	(Y)←(Y)-1	(Y)=15	X	Decrements contents of register Y by 1. Skips next instruction when new contents of register Y are "15".	
	LCPS i	0	0	1	0	0	0	0	4	(CPS)←i, where, i=0,1		X	DP and CY are active when i=0. DP and CY, when i=1.	
Register-register transfers	TAB	0	0	0	0	1	1	1	1	(A)←(B)		X	Transfers contents of register B to register A.	
	TBA	0	0	0	0	1	1	1	0	(B)←(A)		X	Transfers contents of register A to register B.	
	TAY	0	0	0	0	1	1	0	1	(A)←(Y)		X	Transfers contents of register Y to register A.	
	TYA	0	0	0	0	1	1	0	0	(Y)←(A)		X	Transfers contents of register A to register Y.	
	TLA	0	0	0	0	1	1	0	1	(L)←(A)		X	Transfers contents of register A to register L.	
	THA	0	0	0	0	1	1	0	1	(H)←(A)		X	Transfers contents of register A to register H.	
	TEAB	0	0	0	0	1	1	0	1	(E)←(E)∪(B), (E)←(E)∩(A)		X	Transfers contents of registers A and B to register E.	
	TEPA	0	0	0	0	1	1	0	1	(E)←(E)∪(A) through PLA		X	Decodes contents of register A in the PLA and transfers result to register E.	
	TAJ	0	0	0	0	1	1	0	0	(A)←(A)∩(J) when, (Y) ₇ =0 (A)←(A)∪(J) when, (Y) ₇ =1 (A)←(A)∩(J) when, (Y) ₆ =2 (A)←(A)∪(J) when, (Y) ₆ =3		X	Transfers designated contents of register J to register A.	
	XAL	0	0	0	0	1	1	0	0	(A)←(L)		X	Exchanges contents of register A with contents of register L.	
XAH	0	0	1	0	1	1	0	0	(A)←(H)		X	Exchanges contents of register A with contents of register H.		
RAM-accumulator transfers	TAM j	0	0	1	1	0	1	0	4	(A)←(M(DP)) (X)←(X)∪i, where, j=0-3		X	Transfers the RAM contents addressed by the active DP to register A. Register X is then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X.	
	XAM j	0	0	1	1	0	0	1	0	(A)←(M(DP)) (X)←(X)∪i, where, i=0-3		X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value i, and the result stored in register X.	
	XAMd j	0	0	1	1	0	1	0	0	(A)←(M(DP)), (Y)←(Y)+1 (X)←(X)∪i, where, i=0-3	(Y)=15	X	Exchanges the contents of the RAM and register A. Contents of Y are then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X. The contents of register Y are decremented by 1, and when the result is 15, the next instruction is skipped.	
	XAMi j	0	0	1	1	0	1	1	0	(A)←(M(DP)), (Y)←(Y)+1 (X)←(X)∪i, where, i=0-3	(Y)=masked skip condition	X	Exchanges the contents of the RAM and register A. Contents of Y are then "exclusive OR-ed" with the value j in the instruction and result stored in register X. The contents of register Y are incremented by 1, and when the result meets with the masked skip condition, the next instruction is skipped.	
Arithmetic operations	LA n	0	1	0	1	1	1	1	1	(A)←n, where, n=0-15	Written successively	X	Loads the value n into register A. When LA is written consecutively the first is executed, and successive ones are skipped.	
	AM	0	0	0	0	1	0	0	0	(A)←(A)-(M(DP))		X	Adds the contents of the RAM to register A. The result is retained in register A, and the contents of flag CY are unaffected.	
	AMC	0	0	0	0	1	0	0	1	(A)←(A)+(M(DP))+(CY) (CY)←carry		0	Adds the RAM contents addressed by the active DP and contents of flag CY to register A. The result is stored in register A and the carry in the active flag CY.	
	AMCS	0	0	0	0	1	1	1	0	(A)←(A)-(M(DP))-(CY) (CY)←carry	(CY)=1	0,1	Adds the contents of the RAM and flag CY to register A. The result is stored in register A and the carry in the CY, but the next instruction is skipped when a carry is produced.	
	A n	0	1	0	1	0	1	1	1	(A)←(A)+n, where, n=0-15	A carry=0 but, n≠6	X	Adds value n in the instruction to register A. The contents of flag CY are unaffected and their next instruction is skipped if a carry is not produced, except when n=6.	
	SC	0	0	1	0	0	1	0	0	1	(CY)←1		1	Sets active flag CY.
	RC	0	0	1	0	0	0	0	0	1	(CY)←0		0	Resets active flag CY.
Bit operations	SZC	0	0	1	0	1	1	1	0	2		X	Skips next instruction when contents of the active flag CY are 0.	
	DMA	0	1	0	0	0	1	1	1	0	0	X	Stores complement of register A in register A.	
	SB j	0	0	1	0	0	1	1	1	0	4	X	Sets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	RB j	0	0	1	0	1	1	1	0	5	0	X	Resets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
Comparisons	SZB i	0	0	0	1	0	0	1	1	0	2	X	Skips next instruction when the contents of the jth bit of the RAM addressed by the active DP (the bit which is designated by the value j in the instruction) are 0.	
	SEAM	0	0	0	1	0	1	0	0	2	6	X	Skips next instruction when contents of register A are equal to the RAM contents addressed by the active DP.	
SEY y	0	0	0	1	1	1	1	0	3	y	1	X	Skips next instruction when the contents of register Y are equal to the value j in the instruction.	
A/D converter operations	LC7	0	0	1	0	1	1	1	1	0	5	X	Loads 7 to register C.	
	DEC	0	0	0	0	1	0	0	1	0	9	X	Decrements contents of register C by 1, when result is 7, skips next instruction.	
	SHL	0	0	1	0	0	0	1	0	2	1	X	Sets the bit in register L or H designated by register C. The box instruction shows the relationship between register C and bit position.	
	RHL	0	0	1	0	1	0	1	0	5	2	X	Resets the bit in register L or H that is designated by register C.	
	CPA	0	0	0	0	0	1	0	0	8	1	X	Reads all analog values from input port K for comparison with D-A converter output V _{ref} , and either sets the respective bit of register J to the next instruction cycle, whenever V _{ref} < V _{K(i)} is true, or resets it, whenever V _{ref} > V _{K(i)} is true.	
	CPAS	0	0	1	0	1	0	0	1	5	1	X	Reads and stores temporarily all analog values from the input port K, which are the unaffected by changes in start K inputs. These values are compared with the D-A converter output V _{ref} calculated from contents of registers H and L and respective bits of register J are set/reset.	
	CPAE	0	0	1	0	1	0	0	0	6	0	X	Terminates execution of instruction CPAS. Contents of register J remain unaffected, maintaining the value immediately before termination, and input port K is again ready to receive inputs.	
SZJ	0	0	0	1	0	0	1	0	2	9	X	Skips next instruction when the bit in register J, designated by register Y, is 0. The next instruction is unconditionally skipped when the contents of register Y are 15.

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V_{DD}	Supply voltage		0.3 ~ -20	V
V_I	Input voltage, port S and D inputs	With respect to V_{SS}	0.3 ~ -35	V
V_I	Input voltage, inputs other than port S and D		0.3 ~ 20	V
V_O	Output voltage, port S and D outputs		0.3 ~ -35	V
V_O	Output voltage, outputs other than port S and D		0.3 ~ -20	V
P_C	Power dissipation		$T_a = 25^\circ\text{C}$	1.00
T_{opr}	Operating temperature		10 ~ 70	$^\circ\text{C}$
T_{stg}	Storage temperature		40 ~ 125	$^\circ\text{C}$

RECOMMENDED OPERATING CONDITIONS ($T_a = -10 \sim 70^\circ\text{C}$, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Typ	Max	
V_{DD}	Supply voltage	-13.5	-15	16.5	V
V_{SS}	Supply voltage		0		V
V_{IH}	High-level input voltage	1.5		0	V
$V_{IH}(\phi)$	High-level clock input voltage	-1.5		0	V
V_{IL}	Low-level input voltage, inputs other than port D and S	V_{DD}		4.2	V
V_{IL}	Low-level input voltage, port D and S inputs	-33		-4.2	V
$V_{IL}(\phi)$	Low-level clock input voltage	V_{DD}		$V_{DD} - 2$	V
$V_{I(K)}$	Analog input voltage, port K input	V_{REF}		0	V
V_{REF}	Reference voltage	-5		7	V
V_{OL}	Low-level output voltage, port D and S outputs	-33		0	V
f_{clk}	Internal clock operation frequency	300		600	kHz

Note 1: $V_{IL}(\phi)$ is specified with respect to the maximum value of V_{DD} . The maximum allowable value is -23V when using a ceramic resonator with the M58841-XXXP. This maximum allowable value is -1V for $V_{IL}(\phi)$ when using the M58840-XXXP.

ELECTRICAL CHARACTERISTICS ($T_a = -10 \sim 70^\circ\text{C}$, $V_{DD} = -15\text{V} \pm 10\%$, $V_{SS} = 0\text{V}$, $f_{clk} = 300 \sim 600\text{kHz}$, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max

I_{IH}	High-level input current, port K (enhancement load)	$V_{DD} = 15\text{V}$, $V_{IH} = 0\text{V}$, $T_a = 25^\circ\text{C}$	40		200	μA
I_{IH}	High-level input current, PFSL1	$V_{DD} = 15\text{V}$, $V_{IH} = 0\text{V}$, $T_a = 25^\circ\text{C}$	30		100	μA
I_I	Input current, port K inputs	To be measured when the instruction CPAS or CPA is not being executed. $V_I = -7\text{V}$			-7	μA
$I_{I(\phi)}$	Clock input current	$V_I(\phi) = 15\text{V}$, $T_a = 25^\circ\text{C}$		-20	40	μA
I_{OH}	High-level output current, port D outputs	$V_{DD} = 15\text{V}$, $V_{OH} = 2.5\text{V}$, $T_a = 25^\circ\text{C}$			-15	mA
I_{OH}	High-level output current, port S outputs	$V_{DD} = 15\text{V}$, $V_{OH} = 2.5\text{V}$, $T_a = 25^\circ\text{C}$			-8	mA
I_{OL}	Low-level output current, port D and port S outputs	$V_{DD} = -33\text{V}$, $T_a = 25^\circ\text{C}$			33	μA
I_{DD}	Supply current from V_{DD}	$V_{DD} = -15\text{V}$, $T_a = 25^\circ\text{C}$			-41	mA
I_{REF}	Current from V_{REF}	$V_{REF} = -7\text{V}$, $T_a = 25^\circ\text{C}$			0.7	mA
C_I	Input capacitance, port K inputs	$V_{DD} = V_I = V_O = V_{SS}$, $f = 1\text{MHz}$ 25mVrms		7	10	pF
$C_{I(\phi)}$	Clock input capacitance	$V_{DD} = X_{OUT} = V_{SS}$, $f = 1\text{MHz}$ 25mVrms		7	10	pF
	A-D conversion linearity error	$V_{REF} = 7\text{V}$	Overall	-2	1.3	LSB
	A-D conversion zero error	$V_{REF} = 7\text{V}$				
	A-D conversion full scale error	$V_{REF} = 7\text{V}$				

Note 2: Currents are taken as positive when flowing into the IC (No sign), with the minimum and maximum values as absolute values.

3: The overall sum of the port D high-level output currents should be kept below 75mA.

4: The negative threshold voltage, hysteresis, high-level input current (depletion load), and high-level input current. For reset refer to the M58841-XXXP.

5: The high-level input current (enhancement load), refer to the M58840-XXXP.

DOCUMENTATION REQUIRED UPON ORDERING

The following information should be provided when ordering a custom mask.

- (1) M58840-XXXP, M58841-XXXSP mask confirmation sheet.
- (2) ROM data 3 EPROM sets
- (3) S output PLA coding On confirmation sheets
- (4) Interrupt input Schmitt circuits On confirmation sheets
- (5) M58840-XXXP reset circuits On confirmation sheets
- (6) Port K pulldown transistors On confirmation sheets
- (7) Port K input discharge transistors On confirmation sheets

MASK OPTIONS

The following type of mask options are available, specifiable at the time of ordering

- (1) S output PLA data
- (2) Interrupt input Schmitt circuit
- (3) M58840-XXXP reset circuit
- (4) Port K input pulldown resistors
- (5) Port K input discharge transistors

MELPS 4 SYSTEM EVALUATION DEVICE

DESCRIPTION

The M58842S MELPS 4 system evaluation device is designed to emulate the M58840-XXXP, M58841-XXXP, M58843-XXXP and M58844-XXXP single-chip 4-bit micro-computer. It has been developed using P-channel aluminum-gate ED-MOS technology, and has a 64-pin ceramic DIL package. The M58842S facilitates fast development of new systems by using a program memory ROM external to the M58842S.

FEATURES

- Except for the mask ROM, all functions are equivalent to the M58840-XXXP.
- RAM capacity 128-word x 4-bit
- Single - 15V power supply
- Built-in A/D converter/(15 analog inputs)
- Two data pointers
- Subroutine nesting 3 levels
- Analog/digital input ports (K ports) 15
- I/O ports (ports D, S) 19
- Capable of direct drive of large fluorescent display tubes
- Interrupt 1 level
- Internal PLA (mask option) for port S
- Internal clock generator

APPLICATION

- System development and prototyping of equipment using the M58840-XXXP, M58841-XXXP, M58843-XXXP, and M58844-XXXP single-chip 4-bit microcomputers.

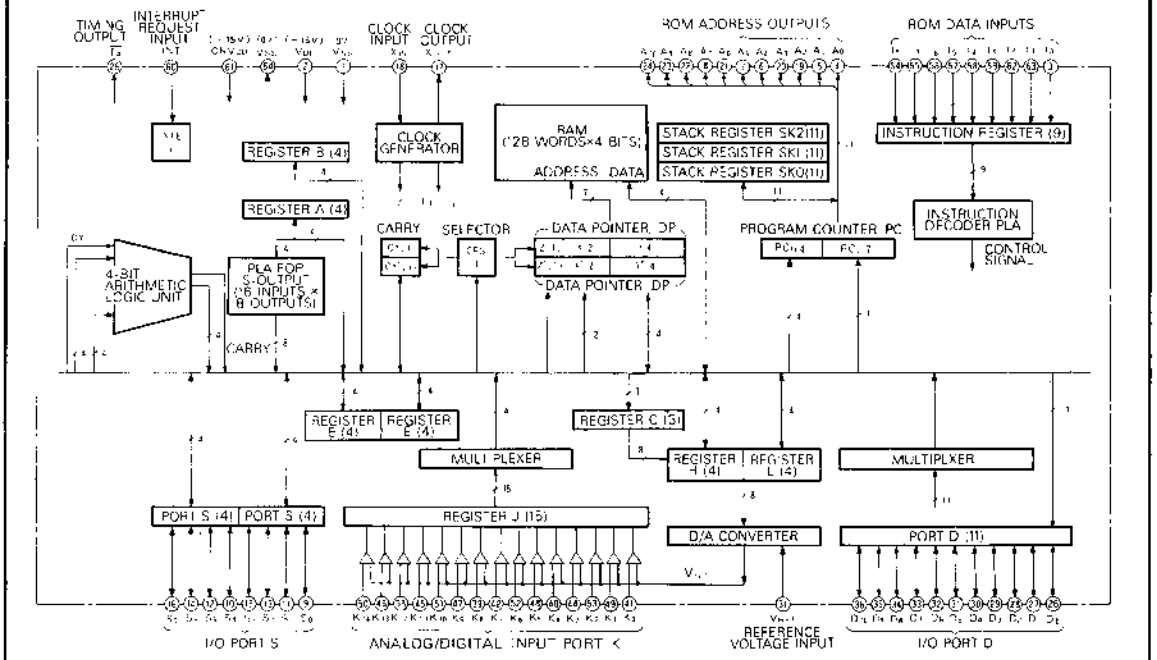

PIN CONFIGURATION (TOP VIEW)

Outline 64S1

4

BLOCK DIAGRAM

MELPS 4 SYSTEM EVALUATION DEVICE

FUNCTION

The M58842S MELPS 4 system evaluation device has the same functions as the M58840-XXXP single-chip 4-bit microcomputer except for the program memory ROM, which must be provided for from an external source connected through the address output pins ($A_0 \sim A_{10}$) and instruction input pins ($I_0 \sim I_3$).

In using the single-chip 4-bit microcomputer to control the operations of equipment, the operational procedures have to be put in a program and stored in the program memory (ROM). It may, however, consume a lot of time and effort, not to mention the cost, when a program correction is needed. This would naturally call for simulation of the application program before masking it into a ROM. In order to satisfy such a requirement, the M58842S has been prepared for evaluating a trial program before programming it into a mask-programmable ROM.

When using the M58842S for evaluating the M58841-XXXSP, M58843-XXXP and M58844-XXXP which are partially different from the M58840-XXXP (e.g. in the

number of I/O ports), use the appropriate pins only. For example, since the M58843-XXXP is provided with a 1K-word ROM, use the last 1K words of the M58842S. Also since only the K_0 to K_3 ports are available, use K_0 through K_3 of the M58842S.

DESCRIPTION OF OPERATION

Programmable Logic Array (PLA) for the S-Output

The standard code listed below is stored in the PLA for the S-output. This code is used for numerical indication on 7-segment display units.

Input of ROM Data

Machine instructions can be executed by the M58842S if input from an external source. During the state T_2 , the ROM address signal appears on the ROM address output pins $A_0 \sim A_{10}$. Then ROM data corresponding to this address should be applied to the ROM data input pins $I_0 \sim I_8$ during state T_6 . For further details, refer to the instruction fetch timing diagram. During this application the input pin CNV_{DD} should be connected to V_{DD} .

MELPS 4 SYSTEM EVALUATION DEVICE

PIN CONFIGURATION

Pin	Name	Input or output	Function
K ₁ : K ₁₄	Analog input port K	In	Analog port K has 15 independent analog input terminals. All signals applied to the 15 input lines of port K are simultaneously compared with the V_{REF} generated by the D-A converter. Corresponding bits of register J are set when the condition, $ V_{REF} > V_K(\gamma)$ is met. This port is utilized for receiving input signals from the touch panel or receiving analog inputs from temperature and other sensing devices. It can also be used as a value threshold digital signal input port when the V_{REF} is properly selected.
S ₀ : S ₇	I/O port S	In/out	The I/O port S can be used as either an 8-bit output port or a pair of 4-bit input ports. Since it has open-drain circuits, it is suitable for directly driving segments of a large fluorescent display tube. It has an 8-bit output latch and can perform to drive 8 bits simultaneously. When the output of port S is programmed to low level, it remains in the floating (high-impedance) state so that it can be used as an input port.
D ₀ : D ₁₀	I/O port D	In/out	The I/O port D is composed of 11 bits that can be used as discrete I/O units. Latches are provided on the output side to maintain individual output signals. When port D output is programmed to low-level, to keep it in floating (high-impedance) state, it can be used as a sense input port. The level of the input signal is sensed at the input terminal and is tested to determine if it is high or low by executing a skip instruction.
A ₀ : A ₁₀	ROM address output	Out	The address output is composed of 11 bits that output the contents of the program counter PC to the external program memory (ROM).
I ₀ : I ₈	ROM data input	In	The data input is composed of 9 bits that are used to fetch the instruction code for the CPU from the external program memory (ROM).
X _{IN}	Clock input	In	As the clock generator is contained internally, clock frequency is determined by connecting an external CR circuit or an LF ceramic resonator between the pins X _{IN} and X _{OUT} . In case an external clock source is to be used, it should be connected to the pin X _{IN} , leaving the pin X _{OUT} open.
X _{OUT}	Clock output	Out	This pin generates the clock frequency from the internal clock oscillation circuit. The oscillation frequency is controlled by connecting the CR circuit or LF ceramic resonator between this pin and the pin X _{IN} .
INT	Interrupt request input	In	This signal is used for requesting interrupts. Whether high or low-level interrupt signals are in used for requests is selected by means of the program. When the instruction INT is executed, interrupt is accepted with a high-level signal, and accepted with a low-level signal when the instruction NTL is executed. When an interrupt is requested and accepted, program execution is jumped to address 0 of page 12. The instruction RTI is used for the return instruction.
V _{REF}	External reference voltage input	In	A reference voltage input is applied to the D-A converter from the external terminal. Its nominal value is $V_{REF} = 7V$. The value $(n-0.5)V_{REF}/256$ is generated by the D-A converter, and is compared with the analog signals from the input port K, where n represents the contents of the register H, but when n = 0, the output voltage is treated as 0V. It can also be used as an automatic reset signal input. When a high-level is applied to the V _{REF} input, it actuates the automatic reset circuit, and then the V _{REF} input is changed to low-level ready to start the program from address 0 of page 0.
T _A	Timing output	Out	This pin generates a part of the basic timing pulse. This signal is used for testing other devices incorporated in the system.
CNVDD	CNVDD input	In	This input terminal should be connected with the VDD and have a low-level input (15V) applied.

APPLICATION EXAMPLE

MITSUBISHI MICROCOMPUTERS

M58843-XXXP, M58844-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

DESCRIPTION

The M58843-XXXP and M58844-XXXSP are single-chip 4-bit microcomputers fabricated using p-channel aluminum gate ED-MOS technology. They include an on-chip 8-bit A-D converter. The M58843-XXXP is housed in a 28-pin plastic moulded DIL package while the M58844-XXXSP is housed in a 40-pin shrink plastic molded DIL package.

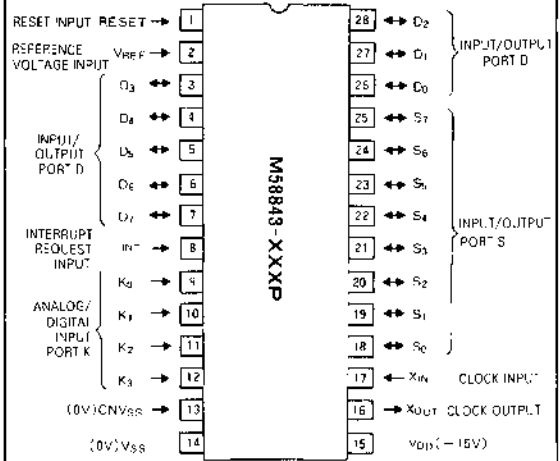

FEATURES

- Basic machine instructions 67
- Basic instruction execution time
(for single-word instructions using
a 600kHz clock frequency) 10 μ s
- Memory capacity ROM 1024 words x 9 bits
RAM 64 words x 4 bits
- Single -15V power supply
- Built-in 8-bit A-D converter
- Two built-in data pointers
- Subroutine nesting 3 levels
- Analog/digital inputs (port K)
 - M58843-XXXP 4 lines
 - M58844-XXXSP 11 lines
- Input/output (ports D and S)
 - M58843-XXXP 16 lines
 - M58844-XXXSP 19 lines
- Capable of driving large fluorescent tube displays
- Interrupt function 1 factor, 1 level
- Built-in port S output decoder PLA (mask option)
- Built-in pull-down transistors (ports D, K, and S, mask option)
- Built-in clock generator circuit

APPLICATIONS

- Electronic ranges, air conditioners, heaters, washing machines, rice cookers
- Office equipment, copying machines

PIN DESCRIPTIONS

Pin	Name	Input/output	Function
V _{DD} V _{SS}	Power supplies	In	V _{DD} and V _{SS} are applied as -15V ±10% and 0V respectively.
K ₀ - K ₃ (M58843-XXXP) K ₀ - K ₁₀ (M58844-XXXSP)	Analog/digital input port K	In	The input port K consists of 4 (11 for the M58844-XXXSP) independent analog input pins. They can be programmed to receive digital quantities as well.
S ₀ - S ₇	Input/output port S	In/out	The I/O port S can be used as either an 8 bit output port or a pair of 4 bit input ports. Since it has open drain circuits, it is suitable for directly driving segments of a large fluorescent display tube. When the output port S is programmed to a low level, it remains in the floating state (high-impedance) so that it can be used as an input port.
D ₀ - D ₃ (M58843-XXXP) D ₀ - D ₁₀ (M58844-XXXSP)	Input/output port D	In/out	Port D consists of 8 bits for the M58843-XXXP and 11 bits for the M58844-XXXSP, all bits operating individually for input and output functions. When a port D output is programmed to low, the output floats (goes to high-impedance state) and the input signal can be sensed.
X _{IN}	Clock input	In	A clock generator is built into the device so that the clock frequency is determined by connecting an external RC circuit or ceramic resonator between pins X _{IN} and X _{OUT} . When an external clock source is used, it should be connected to the X _{IN} pin, leaving the X _{OUT} pin open.
X _{OUT}	Clock output	Out	This pin is the output of the built-in clock generator circuit. The oscillation frequency is controlled by connecting an RC circuit or ceramic resonator element between this pin and the X _{IN} pin.
INT	Interrupt request input	In	This pin is used to input the interrupt request signal. The level of the interrupt signal can be programmed as either high or low.
V _{REF}	Reference voltage input	In	This is the input for the reference voltage applied to the D-A converter.
CNV _{SS}	CNV _{SS} input	In	This input is connected to V _{SS} and must have a high-level input applied to it (0V).
RESET	Reset input	In	When this input is kept high for at least two machine cycles, the reset state is enabled.
V _P (M58844-XXXSP only)	Pull-down voltage input	In	This pin is used to supply the pull-down voltage for port D outputs and port S outputs.

MITSUBISHI MICROCOMPUTERS M58843-XXXP, M58844-XXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

BASIC FUNCTION BLOCKS

Program Memory (ROM)

This 1024-word x 9-bit mask programmable ROM can be programmed with machine instruction codes in accordance with the customer's specifications. It consists of 8 pages, each containing an address range of 0 ~ 127. Fig. 1 shows the address map of this ROM.

Program Counter (PC)

This counter is used to specify ROM addresses and the sequence of read-out of instructions stored in ROM. The program counter (PC) is an 10-bit binary counter, the upper order 3 bits of which (PC_H) indicate the ROM page, and the lower order 7 bits of which (PC_L) are a pure binary address designation. Each time an instruction is executed, PC_L is incremented by one step. For branching, and subroutine call instructions, its value is set to the designated address.

When the 127th address is reached for every page, the address value returns to the first address of that page. Therefore, for moving from one page to another page, the page byte itself must be modified. This is done using the BL and BLA instructions.

Page 14 and page 15 are special pages used for subroutine calls. The page 14 subroutine can be called with a one word instruction from any arbitrary page. This instruction is either BM or BMA. When either BM or BMA is executed, subsequent BM or BMA instructions are equivalent to B and BA on page 14. Also, B or BA is equivalent to B or BA on page 15. This condition is cancelled when the RT, RTS, BL, BML, BLA or BMLA instruction is executed. Note 3 under the instruction codes shows corresponding states.

Stack Registers (SK_0, SK_1, SK_2)

These registers are used to temporarily store the contents of the PC while executing subroutines or interrupt programs until the program returns to its original routine. The SK registers are organized in three words of 10 bits each, enabling up to three levels of subroutine nesting. If one word is used for an interrupt routine, the remaining two levels can be used for subroutine calls.

Data Memory (RAM)

This 256-bit (64 words x 4 bits) RAM is used to store both processing and control data. One RAM word consists of 4 bits with bit manipulation possible over the entire storage area. The 64 words are arranged as 4 files x 16 digits x 4 bits. Fig. 2 shows the RAM address map.

The RAM address specification is made by the combination of data pointer DP register X, and register Y. Thus, the selector CPS and data pointer DP must be set. However, as

long as the address is not changed this is not necessary.

Data Pointers (DP, DP')

These registers are used to designate RAM address, and bit position for the I/O port D and register J. Each data pointer is composed of a 6-bit register group. Register X (the upper order 2 bits of DP) designates a RAM file; and register Y (the lower order 4 bits of DP) designates the digit position of the RAM file. At the same time, register Y designates bit positions of the I/O port D and register J.

4-bit Arithmetic Logic Unit (ALU)

This unit executes 4-bit arithmetic and logical operations by means of a 4-bit adder and related logic circuitry. The arithmetic logic unit performs addition, logical comparisons, arithmetic comparisons, and bit manipulation.

Register A and Carry flag (CY)

Register A is a 4-bit accumulator that constitutes the basis for arithmetic operations. Data processing operations such as arithmetic and logical operations, data transfer, exchange, conversion and data input/output are executed by means of this register. Carry or borrow from register is stored in the carry flag's CY and CY' after execution of arithmetic or logical operations. The carry flags CY and CY' can also be used as 1-bit flags. Carry flags and data pointer DP selection is done by means of the selector CPS.

Registers B and E

Register B is composed of 4 bits and can be used as a 4-bit temporary storage register or for 8-bit data transfer in conjunction with register A. Register E is composed of 8 bits and is used not only as an 8-bit temporary storage register, but also as a temporary storage register for I/O port S.

Fig. 2 RAM Address map

A/D Conversion Circuit

The following A/D conversion functions are controlled by software as described below. Fig. 3 shows the block diagram.

(1) Comparators

These comparators are implemented entirely with PMOS devices and use a chopper-type amplification method. They are capable of determining the larger of the D-A converter output V_{ref} and the port K input signals $V_{K(Y)}$ (where $Y = 0 \sim 10$).

(2) Register J

Register J is composed of 11 1-bit registers, each representing the comparison result from the comparators. All register bits are set simultaneously. The value of the register J with respect to the comparison results is as follows.

- 1 when $|V_{ref}| > |V_{K(Y)}|$
- 0 when $|V_{ref}| < |V_{K(Y)}|$

In this relationship (Y) represents the bit position in register J which is designated by register Y. The comparison results can be checked for each bit using the SZJ instruction.

(3) Registers H - L

These two 4-bit registers are capable of transferring and exchanging data to and from register A.

The 8-bit digital data for the D-A converter is transferred from these registers, the higher order 4 bits from H and lower order 4 bits from L.

(4) Register C

This 3-bit register is used as a counter to designate bit positions in the H and L registers.

(5) D-A Converter

The D-A converter converts the digital values stored in the registers H and L, referencing with the external reference voltage V_{REF} applied at the pin V_{REF} , to the analog value of the internal reference voltage V_{ref} .

The theoretical value of the internal reference voltage V_{ref} is defined as follows.

$$V_{ref} = \frac{n-0.5}{256} \times V_{REF}, \text{ where, } n = 1, 2, \dots, 255$$

$$V_{ref} = 0, \text{ where, } n = 0$$

In the above relationships n is the value weighted according to the contents of registers H and L.

A-D Conversion Algorithms

A-D conversion is controlled by the programming of the previously described functional blocks. Thus, by modifying the program, either the successive approximation method or the sequential comparison method may be selected. In addition, a digital input of high or low level may be used to select the method, eliminating software selection of the A-D conversion technique.

(1) Successive Approximation

In this method, the conversion speed is maintained constant regardless of the amplitude of the analog signal. The A-D conversion process requires 0.6ms (at 600KHz clock frequency). 12 program words are required.

(2) Sequential Comparison

In this method the conversion speed varies in accordance with the rate of change of the analog quantity. When the rate of change is slow, the conversion rate increases. 30 program words are required.

**SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH 8-BIT A/D CONVERTER**

Interrupt

The flag INTE is a 1-bit flip-flop used to control interrupt operation. When an interrupt request signal is applied to the pin INT while the interrupt is enabled, the INTE flag is reset to disable further interrupts, after which the program jumps from the main program to address D of page 12. When an interrupt program is used, one level of the three-level stack register is required, the remaining two levels being used for subroutines. After the interrupt program is started, the data pointer DP, register A, carry flag CY, and registers used by the interrupt program are saved. It is necessary to restore these before returning to the main program by using the instruction RTI.

When an interrupt occurs, the microcomputer internal states are as follows.

(1) Program Counter

The current address in the main program is stored in a stack register and the program counter is set to page 12, address 0.

(2) Interrupt Flag INTE

The flag INTE is reset to disable further interrupts. This disable state will continue even after the program has returned from the interrupt routine to the main program by the execution of the RTI instruction. EI is executed and when the input level of the INT input changes, this state is disabled. Thus, when the INT instruction is executed the interrupt state is enabled when the INT input goes high. As long as it remains in the high state, further interrupts are prohibited. If the INT input should change to a low level and return to high, the next interrupt will be accepted.

(3) Skip Flags

Skip flags are provided to discriminate skip instructions and consecutively described skip instructions. Each flag has its own stack within which the skip state is saved.

As a mask option, the interrupt pins may be provided with Schmitt input circuits.

Input/Output Pins

(1) Input port K

The input port K consists of 4 bits for the M58843-XXXP and 11 bits for the M58844-XXXSP. The voltage level input at these pins is compared with the D-A converter voltage output V_{ref} by a comparator and the results stored in register J. As a mask option, it is possible to build load resistors into the input port K. These are implemented using depletion-type MOS transistors. In addition, to enable the use of capacitive touch-type keys, it is possible to provide these inputs with the required discharge transistors.

(2) Input/Output Port S

The input/output port S consists of 8 bits, each bit

with an output latch. These latches are used to store data transferred by means of a PLA from register A, or data transferred from register A and register B directly, or data transferred from register E directly. 4 bits at a time of the 8 input bits of port S may be transferred to register A.

Because port S outputs are provided with a built-in PLA, it is possible to output any arbitrarily settable 8-bit code from an input specified by register A. These PLA output codes can be specified arbitrarily as a mask option.

In addition, as a mask option, it is possible to build-in load resistors at the input/output port S. The load resistors are implemented with depletion-type MOS transistors.

(3) Input/Output Port D

The input/output port D consists of 8 bits for the M58843-XXXP and 11 bits for the M58844-XXXSP. Each bit can be individually designated as either input or output and is provided with its own latch. The contents of the data pointer register Y can be used to designate a single bit of port D for output or sensing.

In addition, as a mask option load resistors may be built-in at the input/output port D. These resistors are implemented by means of depletion-type MOS transistors.

When port S or port D is used as an input port, the output should first be cleared to the low state.

Reset Function

When the RESET input is kept high for at least two machine cycles, the reset state is enabled. As shown in Fig. 4, it is possible to implement a power-on reset circuit using an externally connected capacitor, resistor and diode. For this configuration, when the supply voltage falls below $-13.5V$, the circuit design should insure that the RESET input is above $-4V$.

When the reset state is enabled, the following operations are performed.

(1) The program counter is set to page 8, address 0

(PC) \leftarrow 0

Note 1 The M58843-XXXP and M58844-XXXSP programs are developed using a support system having a 2048 word \times 9-bit ROM memory. When using such a system pages 8 through 15 of the 2048 words (pages 0 through 15) are used so that the program counter $PC_{14} = 0 \sim 7$ is defined as pages 8 through 15.

(2) The interrupt mode is in the interrupt disabled state

(INTE) \leftarrow 0

This is the same state as when the instruction DI is executed.

(3) By setting the interrupt request signal INT to high, the interrupt enabled state is entered. This is the same state

MITSUBISHI MICROCOMPUTERS M58843-XXXP, M58844-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

as when the instruction INT_H is executed.

- (4) All outputs of port S are cleared to low (S) ← 0
- (5) All outputs of port D are cleared to low (D) ← 0
- (6) The carry and data pointer selector CPS is cleared to low to designate DP and CY (CPS) ← 0

Fig. 4 Power-on reset

Clock Generator Circuit

A clock generator circuit has been built-in, to allow control of the frequency by means of an externally connected RC circuit or ceramic resonator. In addition, an external clock signal may be applied at the X_{IN} pin, leaving the X_{OUT} pin open. Circuit examples are shown in Fig. 5 to Fig. 7.

Fig. 5 External RC circuit

Fig. 6 Externally connected ceramic resonator

Fig. 7 External clock input circuit

MASK OPTIONS

The following mask options are available, specifiable at the time of initial ordering.

- (1) S output PLA data
- (2) Interrupt input Schmitt circuit
- (3) Port K input pull-down resistors
- (4) Port K input discharge transistors
- (5) Port S input/output pull-down resistors
- (6) Port D input/output pull-down resistors

DOCUMENTATION REQUIRED UPON ORDERING

The following information should be provided when ordering a custom mask.

- (1) M58843-XXXP, M58844-XXXSP mask confirmation sheet
- (2) ROM data 3 EPROM sets
- (3) S output PLA coding On confirmation sheets
- (4) Interrupt input Schmitt circuits On confirmation sheets
- (5) Port K input pull-down resistors On confirmation sheets
- (6) Port K input discharge transistors On confirmation sheets
- (7) Port S input/output pull-down resistors On confirmation sheets
- (8) Port D input/output pull-down resistors On confirmation sheets

4

Note 1: This list shows the machine codes and corresponding machine instructions. D₃~D₀ indicate the low-order 4 bits of the machine code and D₈~D₄ indicate the high-order 5 bits. Hexadecimal numbers are also shown that represent the codes. An instruction may consist of one, two, or three words, but only the first word is listed. Code combination indicated with a bar (-) must not be used.

Note 3: Page relationships for branching by means of branching instructions and subroutine calling instructions.

Note 2: Two-word instruction

Second word	
BL	1 1xxx yyyy
BML	1 0xxx yyyy
BA	1 1xxx XXXX
BMA	1 0xxx XXXX

Three word instruction

	Second word	Third word
BLA	0 0111 pppp	1 1xxx XXXX
BMLA	0 0111 pppp	1 0xxx XXXX

MACHINE INSTRUCTIONS

Type of instruction	Mnemonic	Instruction code				No. of words	No. of cycles	Functions	Skip conditions	Flag CY	Description of operation
		D ₄	D ₃	D ₂	D ₁ D ₀						
Register-to-register transfers	TAR	0 0 0 1	1 1 1 0	0 1 E	1	1	(A) ← (B)	—	X	Transfers contents of register B to register A.	
	TBA	0 0 0 1	1 1 0 0	0 1 C	1	1	(B) ← (A)	—	X	Transfers contents of register A to register B.	
	TAY	0 0 0 1	1 1 0 1	0 1 D	1	1	(A) ← (Y)	—	X	Transfers contents of register Y to register A.	
	TYA	0 0 0 0	1 1 0 0	0 0 C	1	1	(Y) ← (A)	—	X	Transfers contents of register A to register Y.	
	TEAB	0 0 0 1	1 0 1 0	0 1 A	1	1	(E ₁ - E ₂) ← (B), (E ₂ - E ₃) ← (A)	—	X	Transfers contents of registers A and B to register E.	
TEPA	0 0 0 1	0 1 1 0	0 1 E	1	1	(E ₇ - E ₆) ← through PLA ← (A)	—	X	Duplicates contents of register A in the PLA and transfers result to register E.		
RAM addresses	LXY x,y	0 1 1 x x	y y y y	0 C y	1	1	(X) ← x, where x = 0-3 (Y) ← y, where y = 0-15	Written successively	X	Loads value of "x" into register X and of "y" into Y. When LXY is written successively, the first is executed and successive ones are skipped.	
	INY	0 0 0 0	0 0 1 0	0 0 2	1	1	(Y) ← (Y) + 1	(Y) = 0	X	Increments contents of register Y by 1. Skips next instruction when new contents of register Y are "0".	
	DEY	0 0 0 0	0 0 1 1	0 0 3	1	1	(Y) ← (Y) - 1	(Y) = 15	X	Decrements contents of register Y by 1. Skips next instruction when new contents of register Y are "15".	
	LCPS i	0 0 1 0 0	0 0 0 1	0 4 i	1	1	(CPS) _i ← 1, where, i = 0, 1	—	X	DP and CY are active when i = 0. DP ² and CY ² when i = 1.	
RAM-accumulator transfers	TAM j	0 0 1 1 0	0 1 j j	0 6 4	1	1	(A) ← (M(DP)) (X) ← (X) ∨ i, where, i = 0-3	—	X	Transfer the RAM contents addressed by the active DP to register A. Register X is then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X.	
	XAM j	0 0 1 1 0	0 0 j j	0 6 j	1	1	(A) ← (M(DP)) (X) ← (X) ∨ i, where, i = 0-3	—	X	Exchanges the contents of the RAM DP and register A. Contents of X are then "exclusive OR-ed" with the value j and the result stored in register X.	
	XAMD j	0 0 1 1 0	1 0 j j	0 6 8	1	1	(A) ← (M(DP)), (Y) ← (Y) - 1 (X) ← (X) ∨ i, where, i = 0-3	(Y) = 15	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X. The contents of register Y are decremented by 1, and when the result is 15, the next instruction is skipped.	
	XAMI j	0 0 1 1 0	1 1 j j	0 6 C	1	1	(A) ← (M(DP)), (Y) ← (Y) + 1 (X) ← (X) ∨ i, where, i = 0-3	(Y) = 0	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction and result stored in register X. The contents of register Y are when the incremented by 1, and when the result is 0, the next instruction is skipped.	
Arithmetic operations	LA n	0 1 0 1 1	n n n n	0 6 n	1	1	(A) ← n, where, n = 0-15	Written successively	X	Loads the value n into register A. When LA is written consecutively the first is executed, and successive ones are skipped.	
	AM	0 0 0 0 0	1 0 1 0	0 0 A	1	1	(A) ← (A) + (M(DP))	—	X	Adds the contents of the RAM to register A. The result is retained in register A, and the contents of flag CY are unaffected.	
	AMC	0 0 0 0 0	1 1 1 0	0 0 E	1	1	(A) ← (A) + (M(DP)) + (CY) (CY) ← carry	—	0/1	Adds the RAM contents addressed by the active DP and contents of flag CY to register A. The result is stored in register A, and the carry in the active flag CY.	
	AMCS	0 0 0 0 0	1 1 1 1	0 0 F	1	1	(A) ← (A) + (M(DP)) + (CY) (CY) ← carry	(CY) = 1 A carry is not produced and	0/1	Adds the contents of the RAM and flag CY to register A. The result is stored in register A and the carry in the active flag CY. The next instruction is skipped when a carry is produced.	
	A n	0 1 0 1 0	n n n n	0 A n	1	1	(A) ← (A) + n, where, n = 0-15	n = 0 n = 6	X	Adds value n in the instruction to register A. The contents of flag CY are unaffected and their next instruction is skipped if a carry is not produced, except when n = 6.	
	SC	0 0 1 0 0	1 0 0 1	0 4 9	1	1	(CY) ← 1	—	1	Sets active flag CY.	
	RC	0 0 1 0 0	1 0 0 0	0 4 B	1	1	(CY) ← 0	—	0	Resets active flag CY.	
Bit operations	SBJ	0 0 1 0 0	1 1 j j	0 4 C	1	1	(M(DP)) ← 1, where, i = 0-3	—	X	Sets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	RBJ	0 0 1 0 1	1 1 j j	0 5 C	1	1	(M(DP)) ← 0, where, i = 0-3	—	X	Resets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	SZB j	0 0 0 1 0	0 0 j j	0 2 j	1	1	(M(DP)) ← 0 where, i = 0-3	(M(DP)) = 0 where, i = 0-3	X	Skips next instruction when the contents of the jth bit of the RAM addressed by the active DP (the bit which is designated by the value j in the instruction) are 0.	
Compares	SEAM	0 0 0 1 0	0 1 1 0	0 2 6	1	1	(M(DP)) ← (A)	(M(DP)) = (A)	X	Skips next instruction when contents of register A are equal to the RAM contents addressed by the active DP.	
	SEY y	0 0 0 1 1	y y y y	0 3 y	1	1	(Y) ← y, where, y = 0-15	(Y) = y, where, y = 0-15	X	Skips next instruction when the contents of register Y are equal to the value y in the instruction.	
A/D converter operations	TLA	0 0 0 0 1	1 0 0 1	0 1 9	1	1	(L) ← (A)	—	X	Transfers contents of register A to register L.	
	THA	0 0 1 0 1	1 0 0 1	0 5 9	1	1	(H) ← (A)	—	X	Transfers contents of register A to register H.	
	TAJ	0 0 0 0 0	1 1 0 1	0 0 D	1	1	(Y, Y ₆) = 0 when: (A) ← (J ₇ J ₆ J ₅ J ₄) (Y, Y ₆) = 1 when: (A) ← (J ₇ J ₆ J ₅ J ₄) (Y, Y ₆) = 2 when: (A) ← (0 J ₆ J ₅ J ₄) (Y, Y ₆) = 3 when: (A) ← (0 0 0 0)	—	X	Transfers designated contents of register J to register A.	
	XAL	0 0 0 0 1	1 0 0 0	0 1 8	1	1	(A) ← (L)	—	X	Exchanges contents of register A with contents of register L.	
	XAH	0 0 1 0 1	1 0 0 0	0 5 8	1	1	(A) ← (H)	—	X	Exchanges contents of register A with contents of register H.	
	LC7	0 0 1 0 1	0 1 1 1	0 5 7	1	1	(C) ← 7	(C) = 7	X	Loads 7 to register C.	
	DEC	0 0 0 0 0	1 0 0 1	0 0 9	1	1	(C) ← (C) - 1	(C) = 7	X	Decrements contents of register C by 1, when result is 7, skips next.	
	SHL	0 0 1 0 0	0 0 1 0	0 4 2	1	1	(C ₇) = 1 when: (H) _(i-1) ← (H) _i (C ₇) = 0 when: (L) _(i-1) ← (L) _i	—	X	Sets the bit in register L or H designated by register C. The box instruction shows the relationship between register C and bit position.	
	RHL	0 0 1 0 1	0 0 1 0	0 5 2	1	1	(C ₇) = 1 when: (H) _(i+1) ← (H) _i (C ₇) = 0 when: (L) _(i+1) ← (L) _i	—	X	Resets the bit in register L or H that is designated by register C.	
	CPA	0 0 0 0 0	1 0 0 0	0 0 8	1	1	(V _{ref}) > (V _{K(i)}) when: (J ₇) ← 1 (V _{ref}) < (V _{K(i)}) when: (J ₇) ← 0 i = 0-10	—	X	Reads all analog values from input port K for comparison with D-A converter output V _{ref} and either sets the respective bit of register J to the next instruction cycle wherever V _{ref} < V _{K(i)} is true, or resets it wherever V _{ref} > V _{K(i)} is true.	
CPAS	0 0 1 0 1	0 0 0 1	0 5 1	1	1	(V _{ref}) > (V _{K(i)}) when: (J ₇) ← 1 (V _{ref}) < (V _{K(i)}) when: (J ₇) ← 0 i = 0-10	—	X	Reads and stores temporarily all analog values from input port K, which are then unaffected by changes in port K inputs. These values are compared with the D-A converter output V _{ref} , calculated from contents of registers H and L and respective bits of register J are set/reset. Repeated when contents of registers H-L are changed.		
CPAE	0 0 1 0 1	0 0 0 0	0 5 0	1	1	Execution of the instruction CPAS is over, and no more changes will made in (J ₇).	—	X	Terminates execution of Instruction CPAS. Contents of register J remain unaffected, maintaining the value immediately before termination, and input port K is again ready to receive inputs.		
SZJ	0 0 0 1 0	1 0 0 1	0 2 9	1	1	(J ₇) = 0	(J ₇) = 0	X	Skips next instruction when the bit in register J, designated by register Y, is 0.		

MITSUBISHI MICROCOMPUTERS

M58843-XXXP, M58844-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER

Type of instruction	Mnemonic	Instruction code		16-bit notation	No. of words	No. of cycles	Functions	Skip conditions	Flag	Description of operation
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀							
Jumps	B xy	1 1 x x x y y y y	1 8 y +	1 1	1	1	(PC) _n ← 16x + y (PC) _n ← 7, (PC) _n ← 16x + y	—	X	Jumps to address xy of the current page. Jumps to address xy on page 15 when executed, provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after execution of instruction BM or BMA.
	BL pxy	0 0 1 1 1 p p p p 1 1 x x x y y y y	0 7 p + 1 0 y +	2 2	2	2	(PC) _n ← p (PC) _n ← 16x + y	—	X	Jumps to address xy of page p.
	BA xX	0 0 0 0 0 0 0 0 1 1 1 x x x X X X X	0 0 1 + 1 0 x +	2 2	2	2	(PC) _n ← 16x + (A) (PC) _n ← 7, (PC) _n ← 16x + (A)	—	X	Jumps to address x(A) of the current page. Jumps to the address x(A) of page 15 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after execution of instruction BM or BMA.
	BMA pXx	0 0 0 0 0 0 0 0 1 0 0 1 1 1 p p p p 1 1 x x x X X X X	0 0 1 + 0 7 p + 1 0 x +	3 3	3	3	(PC) _n ← p (PC) _n ← 16x + (A)	—	X	Jumps to the address x(A) of page p.
Subroutine calls	BM xy	1 0 x x x y y y y	1 xy	1 1	1	1	(SK2) ← (SK1) ← (SK0) ← (PC) (PC) _n ← 6, (PC) _n ← 16x + y (PC) _n ← 6, (PC) _n ← 16x + y	—	X	Calls for the subroutine starting at address xy on page 14. Jumps to address xy of page 14 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
	BML pxy	0 0 1 1 1 p p p p 1 0 x x x y y y y	0 7 p + 1 xy	2 2	2	2	(SK2) ← (SK1) ← (SK0) ← (PC) (PC) _n ← p, (PC) _n ← 16x + y	—	X	Calls for the subroutine starting at address xy of page p.
	BMA xX	0 0 0 0 0 0 0 0 1 1 0 x x x X X X X	0 0 1 + 1 xX	2 2	2	2	(SK2) ← (SK1) ← (SK0) ← (PC) (PC) _n ← 6, (PC) _n ← 16x + (A) (PC) _n ← 6, (PC) _n ← 16x + (A)	—	X	Calls for the subroutine starting at address x(A) of page 14. Jumps to address xy of page 14 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
	BMLA pXx	0 0 0 0 0 0 0 0 1 0 0 1 1 1 p p p p 1 0 x x x X X X X	0 0 1 + 0 7 p + 1 xX	3 3	3	3	(SK2) ← (SK1) ← (SK0) ← (PC) (PC) _n ← p, (PC) _n ← 16x + (A)	—	X	Calls for the subroutine starting at address x(A) of page p.
Program returns	RTI	0 0 1 0 0 0 1 1 0	0 4 0	1 1	1	1	(PC) ← (SK0) ← (SK1) ← (SK2) Restore internal flip-flop	—	X	Returns from interrupt routine to main routine. The internal flip-flop is restored to the value held immediately before the interrupt.
	RT	0 0 1 0 0 0 1 0 0	0 4 4	1 1	1	1	(PC) ← (SK0) ← (SK1) ← (SK2)	—	X	Returns to the main routine from the subroutine.
	RTS	0 0 1 0 0 0 1 0 1	0 4 5	1 1	2	2	(PC) ← (SK0) ← (SK1) ← (SK2)	Unconditional skip	X	Returns to the main routine from the subroutine, and unconditionally skips the next instruction.
Input/output	SD	0 0 0 0 1 0 1 0	0 1 6	1 1	1	1	(D(Y)) ← 1, where, 0 ≤ (Y) ≤ 10 (D(Y)) ← 0, where, 0 ≤ (Y) ≤ 10 where, 0 ≤ (Y) ≤ 10	—	X	Sets the bit of port D that is designated by register Y.
	RD	0 0 0 0 1 0 0 0	0 1 4	1 1	1	1	(D(Y)) ← 0, where, 0 ≤ (Y) ≤ 10 where, 0 ≤ (Y) ≤ 10	—	X	Resets the bit of port D that is designated by register Y.
	SZD	0 0 0 1 0 1 0 1	0 2 5	1 1	1	1	(D(Y)) ← 0, where, 0 ≤ (Y) ≤ 10 where, 0 ≤ (Y) ≤ 10	(D(Y)) = 0	X	Skip the next instruction if the contents of the bit of port D that is designated by register Y are 0.
	OSAB	0 0 0 0 1 0 1 1	0 1 8	1 1	1	1	(S ₁ - S ₀) ← (B), (S ₁ - S ₀) ← (A)	—	X	Outputs contents of registers A and B to port S.
	OSPA	0 0 0 0 1 0 1 1	0 1 7	1 1	1	1	(S ₁ - S ₀) ← through PLA → (A)	—	X	Decodes contents of register A by PLA and the result is output to port.
	OSE	0 0 0 0 1 0 1 1	0 0 8	1 1	1	1	(S) ← (E)	—	X	Outputs contents of register E to port S.
	IAS i	0 0 1 0 1 0 1 0	0 5 4	1 1	1	1	! = 0 : (A) ← (S ₁ - S ₀) ! = 1 : (A) ← (S ₁ - S ₀)	—	X	Transfers from port S to register A. The high-order four bit of port S are transferred when the value of i in the instruction is 0 or the low-order four bits are transferred when the value of i is 1.
Interrupts	CLD	0 0 0 0 1 0 0 1	0 1 3	1 1	1	1	(D) ← 0	—	X	Clears port D
	CLS	0 0 0 0 1 0 0 0	0 1 0	1 1	1	1	(S) ← 0	—	X	Clears port S.
	CLDS	0 0 0 0 1 0 0 1	0 1 1	1 1	1	1	(D) ← 0, (S) ← 0	—	X	Clears ports S and D.
	EI	0 0 0 0 0 1 0 1	0 0 5	1 1	1	1	(INTE) ← 1	—	X	Sets interrupt flag INTE to enable interrupts.
DI	0 0 0 0 0 1 0 0	0 0 4	1 1	1	1	(INTE) ← 0	—	X	Resets interrupt flag INTE to disable interrupts.	
INTH	0 0 0 0 0 1 1 0	0 0 6	1 1	1	1	(INTP) ← 1	—	X	Sets interrupt polarity flag INTP to enable interrupts when the interrupt request signal is turned high.	
INTL	0 0 0 0 0 1 1 1	0 0 7	1 1	1	1	(INTP) ← 0	—	X	Resets interrupt polarity flag INTP to enable interrupts when the interrupt request signal is turned low.	
Misc	NOP	0 0 0 0 0 0 0 0	0 0 0	1 1	1	1	(PC) _n ← (PC) _n + 1	—	X	No operation
Pin	RESET						(PC) _n ← 0, (PC) _n ← 0	—		Start from address "0" of page 8.
	INT						(SK ₁) ← (SK ₁) ← (SK ₀) ← (PC), (PC) _n ← 4 (PC) _n ← 0	—		Calls for the subroutine starting at address "0" of page 12.

4

Symbol	Contents	Symbol	Contents	Symbol	Contents
A	4-bit register (accumulator)	SK1	10-bit stack register	INT	Interrupt request signal.
B	4-bit register	SK2	10-bit stack register	()	Shows direction of data flow.
C	3-bit register	CV	1-bit carry flag	*	Indicates contents of the register, memory, etc.
E	8-bit register	xx	2-bit binary variable	~	Exclusive OR
H	4-bit register	yyyy	4-bit binary variable	—	Negation.
J	1-bit register	nnnn	4-bit binary constant	X	Indicates flag is unaffected by instruction execution.
L	4-bit register	i	1-bit binary constant	xy	Label used to indicate the address xxxxyy
X	2-bit register	jj	2-bit binary constant	pxy	Label used to indicate the address xxxxyy of page ppxy.
Y	4-bit register	xxxx	4-bit unknown binary number	ops	Indicates which data pointer and carry are active.
DP	6-bit data pointer, combination of registers X and Y.	0	11-bit port	□	Hexadecimal number C + binary number x.
PC _n	The high-order three bits of the program counter.	K	11-bit port	+	
PC ₇	The low-order seven bits of the program counter.	S	8-bit port	X	
PC ₁₀	10-bit program counter, combination of PC ₇ and PC ₃ .	INTE	Interrupt enable flag		
SK0	10-bit stack register	INTP	Interrupt polarity flag		

Note 1. When a skip is used with either the M58843-XXXP or M58844-XXXSP, the next instruction becomes invalid and the program counter is not incremented by 2. Therefore the number of cycles does not change in accordance with the existence or non-existence of a skip. In addition, since the M58843-XXXP is housed in a 28-pin package, some pins of the port K and D are not usable.

Note 2. The M58843-XXXP and M58844-XXXSP programs are developed using a support system having a 2048 word X 9-bit ROM memory. When using such a system, page 8 through 15 of the 2048 words (page 0 through 15) are used so that the program counter PC_n = 0 ~ 7 is defined as page 8 through 15.

Note 3. The crosshatched area indicates invalid input.

MITSUBISHI MICROCOMPUTERS M58845-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER

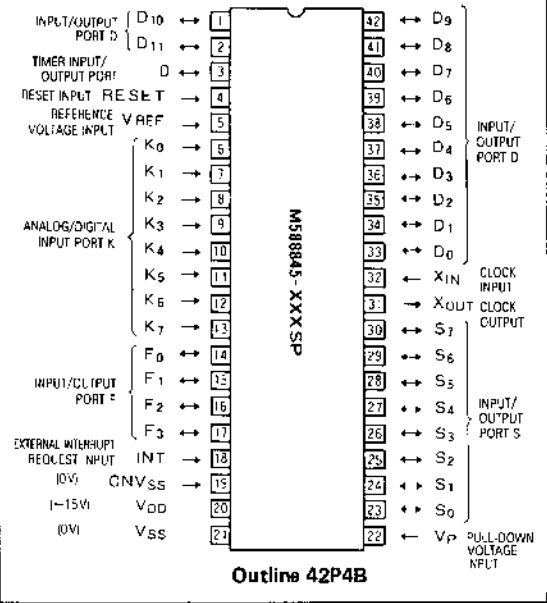

DESCRIPTION

The M58845-XXXSP is a single-chip 4-bit microcomputer developed using p-channel aluminum gate ED-MOS technology. The device includes an 8-bit A-D converter and two timers (one 8-bit timer/counter and one 8-bit timer/event counter). It is housed in a 42-pin shrink plastic molded DIL package.

FEATURES

- Basic machine instructions 77
- Basic instruction execution time (1-word instruction at a clock frequency of 600kHz) 10 μ s
- Memory capacity ROM: 2048 words x 9 bits
RAM: 128 words x 4 bits
- Single -15V power supply
- Built-in 8-bit A-D converter (12 analog inputs)
- Two built-in timers (timer 1: 8-bit timer/counter, timer 2: 8-bit timer/event counter, 7-bit prescaler, timer input/output port T) 2 lines
- Interrupt function
..... 3 factors (external, timer 1, timer 2), 1 level
- Two built-in data pointers
- Subroutine nesting 3 levels
- Analog/digital inputs (port K) 8 ports
- Input/output (ports D, F, and S) 24 ports
- Timer input/outputs (port T) 1 port
- Direct drive for large fluorescent display tubes is possible
- Built-in decoder PLA for port S outputs (mask option)
- Built-in pull-down transistors (ports D, K, and S mask option)
- Built-in clock generator circuit

PIN CONFIGURATION (TOP VIEW)

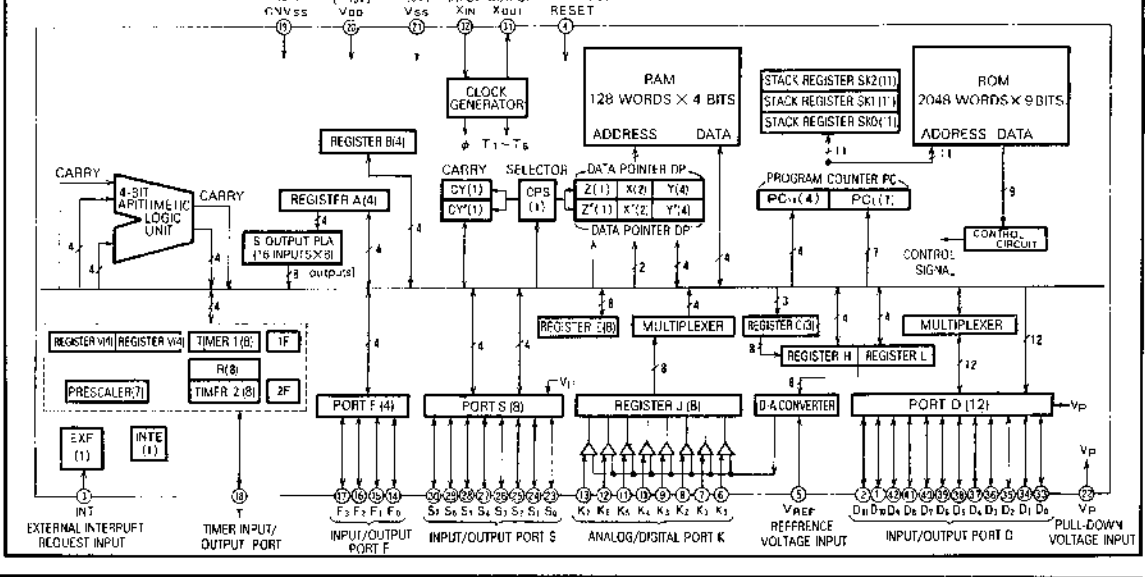

Outline 42P4B

APPLICATIONS

- Microwave ovens, air conditioners, heaters, home sewing machines
- Office equipment, copying machines, medical equipment
- VTR, TVs, cassette decks
- Educational equipment, electronic games

 2. Built-in pull-down transistors (mask option)
 3. Input characteristics mask option (TTL compatible, with a Schmitt circuit)

**SINGLE-CHIP 4-BIT MICROCOMPUTER
 WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER**

PIN DESCRIPTION

Pin	Name	Input or output	Function
V _{SS}	Ground		Connected to 0V potential.
V _{DD}	Supply voltage		Connected to a +5V supply.
V _P	Pull-down supply	In	Input for the supply voltage connected to the load resistors (mask option) for ports D and S.
K ₇ ~K ₀	I/O port K	In	This port can be used for analog and digital input, acting as 8 individual bit inputs or 2 4-bit input groups. Pull-down transistors and input discharge transistors are available as mask options.
D ₁₁ ~D ₀	I/O port D	In/out	Port D consists of a 12-bit input/output port, all bits operating individually. When a port D output is programmed low, the output floats and the input signal can be sensed. The outputs are open drain circuits which can be provided with pull-down transistors as a mask option.
F ₃ ~F ₀	I/O port F	In/out	Port F is a 4-bit input/output port. When the output is programmed to low, the output floats and the input signal can be sensed. The output circuits are open drain circuits.
S ₇ ~S ₀	I/O port S	In/out	The I/O port S can be used as either an 8-bit output port or a pair of 4-bit input ports. When the output port S is programmed to the low level, it remains in the floating state so that it can be used as an input port.
T	Timer I/O port T	In/out	This port is used as the timer to event counter input, and the timer to overflow output, the function being software selectable.
INT	Interrupt request input	In	This is the input for interrupt requests.
RESET	Reset	In	When this input is kept high for at least 3 machine cycles, the reset state is enabled.
V _{REF}	Reference voltage input	In	This is the input for the reference voltage required by the D-A converter.
X _{IN}	Clock input	In	These are the input and output pins for the built-in clock generator. A ceramic resonator (300 kHz ~ 600 kHz) or a resistor/capacitor combination are connected to these pins to provide the required oscillation stability.
X _{OUT}	Clock output	Out	
CNV _{SS}	CNV _{SS}	In	This input is connected to V _{SS} and must have a high-level input applied to it (0V).

4

BASIC FUNCTION BLOCKS

Program Memory (ROM)

This 2048-word x 9-bit ROM can be programmed with machine instruction codes in accordance with the customer's specifications. It consists of 16 pages, each containing an address range of 0~127. Fig. 1 shows the address map for this ROM.

Program Counter (PC)

This counter is used to specify ROM addresses and the sequence of read-out of instructions stored in ROM. The program counter is an 11-bit counter, the upper order 4 bits of which (PC_H) indicate the ROM page, and the lower 7 bits of which are a pure binary address designation. Each time an instruction is executed, PC_L is incremented by 1 step. For branching and subroutine call instructions, its value is set to the designated address.

When the 127 address is reached for every page, the address value returns to the first address of that page. Therefore, for moving from one page to another page, the page byte itself must be modified. This is done using the BL and BLA instructions.

Page 2 and page 3 are special pages used for subroutine calls. Page 2 can be called with a 1-word instruction from any arbitrary page. This instruction is either BM or BMA. When either BM or BMA is executed, subsequent BM or BMA instructions are equivalent to B and BA on page 2.

Also, B or BA is equivalent to B or BA on page 3. This condition is cancelled when the RT, RTS, BL, BML, BLA, or BMLA instruction is executed. Table 3 shows the instruction codes and corresponding states.

Stack Registers (SK₀, SK₁, SK₂)

These registers are used to temporarily store the contents of the PC while executing subroutines or interrupt programs until the program returns to its original routine. The SK registers are organized in 3 words of 11 bits each, enabling up to 3 levels of subroutine nesting. If 1 level is used for an interrupt routine, the remaining 2 levels can be used for subroutine calls.

Data Memory (RAM)

This 512-bit (128 words x 4 bits) RAM is used to store both processing and control data. One RAM word consists of 4 bits with bit manipulation possible over the entire storage area. The 128 words are arranged as 2 file groups x 4 files x 16 digits x 4 bits. Fig. 2 shows the RAM address map. The RAM address specification is made by the combination of data pointer DP register Z, register X, and register Y. Thus, the selector CPS and data pointer DP must be set. However, as long as the address is not changed this is not necessary.

SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER

Data Pointers (DP, DP')

These registers are used to designate the RAM address, and bit position for the I/O port D and register J. Each data pointer is composed of a 7-bit register. Register Z (the most significant bit of DP) designates the RAM file group; register X (the central 2 bits) designates the RAM file; and register Y (the least significant 4 bits) designates the digit position of the RAM file. At the same time, register Y designates the bit positions of the I/O port D and register J.

4-Bit Arithmetic Logic Unit (ALU)

This unit executes 4-bit arithmetic and logical operations by means of a 4-bit adder and related logic circuitry.

Fig. 2 RAM Address map

Register A and Carry Flag (CY)

Register A is a 4-bit accumulator that constitutes the basis for arithmetic operations. Data processing operations such as arithmetic and logical operations, data transfer, exchange, conversion, and data input/output are executed by means of this register. The carry flag CY is used to store carry or overflow after execution of arithmetic and logical operations by the arithmetic logic unit. The carry flag may also be used as a 1-bit flag. Two carry flags, CY and CY', are available and selected by selector CPS, as is the data pointer DP.

Registers B and E

Register B is composed of 4 bits and can be used as a 4-bit temporary storage register or for 8-bit data transfer in conjunction with register A. Register E is composed of 8 bits and is used not only as an 8-bit temporary storage register, but also as a temporary for the I/O port S.

A/D Conversion Circuit

The following A-D conversion functions are controlled by software as described below.

Fig. 3 A-D conversion circuit block diagram

(1) Comparators

The comparators are implemented entirely with PMOS devices and use a chopper-type amplification method. They are capable of determining the larger of the D-A converter output V_{ref} and the port K input signals V_K(Y) (where {Y}=0~7).

(2) Register J

Register J is composed of 8 1-bit registers, each representing the comparison result from the comparators. All register bits are set simultaneously. The value of the register J with respect to the comparison results is as follows.

$$1 \text{ when } |V_{ref}| > |V_K(Y)|$$

$$0 \text{ when } |V_{ref}| < |V_K(Y)|$$

In this relationship Y represents the bit position in register J which is designated by register Y. The comparison results can be checked for each bit using the SZJ instruction.

(3) Registers H and L

These two 4-bit registers are capable of transferring and exchanging data to and from register A. The 8-bit digital data for the D-A converter is transferred from these registers, the higher order 4 bits from H and the lower order 4 bits from L.

(4) Register C

This 3-bit register is used as a counter to designate bit positions in the H and L registers.

(5) D-A Converter

The D-A converter converts the digital values stored in the registers H and L, referencing with the external reference voltage V_{REF} applied at the pin V_{REF}, to the analog value of the internal reference voltage V_{ref}. The theoretical value of the internal reference voltage V_{ref} if defined as follows.

**SINGLE-CHIP 4-BIT MICROCOMPUTER
 WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER**

$$V_{ref} = \frac{n-0.5}{256} \times V_{REF}, \text{ where, } n = 1, 2, \dots, 255$$

$$V_{ref} = 0, \text{ where, } n = 0$$

In the above relationships n is the value weighted according to the contents of registers H and L.

A/D Conversion Algorithms

A/D conversion is controlled by the programming of the previously described functional blocks. Thus, by modifying the program, either the successive approximation method or the sequential comparison method may be selected. In addition, a digital input of high or low level may be used to select the method, eliminating the software selection of the A/D conversion technique.

(1) Successive Approximation Method

In this method, the conversion speed is maintained at a constant 600kHz regardless of the amplitude of the analog signal. The A/D conversion process requires 0.6ms. 12 program words are required.

(2) Sequential Comparison Method

In this method the conversion speed varies in accordance with the rate of change of the analog quantity. When the rate of change is slow, the conversion rate increases. 30 program words are required.

Interrupt Functions

The M58845-XXXSP provides 3-factor, 1-level vector interrupt capability, enabling unique branching addresses for each interrupt factor.

The interrupt vector addresses are shown in Table 1.

Table 1 Vector Interrupt Addresses

Interrupt factor		Interrupt address
Interrupt type	Causal condition	
External interrupt	Rising edge at the INT input pin	Page 1, address 0
Timer 1 interrupt	Timer 1 overflow	Page 1, address 2
Timer 2 interrupt	Timer 2 overflow	Page 1, address 4

An interrupt is generated whenever any of the causal conditions listed in Table 1 are satisfied at a time when the INTE flag is set to 1 (when the EI instruction is executed the INTE flag is set to 1, enabling interrupt; the DI instruction clears this flag to 0, prohibiting interrupts). If any of the interrupt causing conditions continues when the INTE flag is 0, an interrupt is generated when the INTE flag is set to 1.

The interrupts generated as a result of timer 1 and timer 2 overflow conditions can be software controlled, allowing confirmation of the overflow condition using a skip

instruction.

When an interrupt program is used, one level of the three-level stack register is required, the remaining two levels being used for subroutines. After the interrupt program is started, the data pointer DP, register A, carry flag CY, and registers used by the interrupt program are saved. The RTI instruction is required to restore these before returning to the main program.

When an interrupt occurs, the microcomputer internal states are as follows.

(1) Program counter

The current address in the main program is stored in a stack register and the vector interrupt address as shown in Table 4 is loaded into the program counter.

(2) Interrupt flag INTE

The flag INTE is reset to disable further interrupts. This disabled state will continue even after return to the main program by the RTI instruction until the execution of an EI instruction.

(3) Skip flags

Skip flags are provided to discriminate skip instructions and consecutively described skip instructions. Each flag has its own stack within which the skip state is saved. As a mask option, the interrupt pins may be provided with Schmitt input circuits.

Timer/Event Counter (2 Lines)

The timer/event counter section consists of two lines (timers). As shown in Fig. 8, this section includes timer 1 and its overflow flag (1F) and timer 2 and its overflow flag (2F), as well as the timer input/output port T and the timer control registers V and W.

Fig. 4 Timer/event counter block diagram

The two timers (timer 1 and 2) are controlled by means of the timer control registers.

(1) Timer 1

Timer 1 is implemented using an 8-bit binary counter capable of being set and read by means of the T1AB and TAB1 instructions respectively. Starting and stopping of the counter as well as the selection of the source (prescaler or timer 2) is accomplished by means of the timer control register. When an overflow condition occurs, setting the 1F to 1 stops the

**SINGLE-CHIP 4-BIT MICROCOMPUTER
 WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER**

counting operation.

(2) Timer 2

Time 2 is implemented using an 8-bit binary counter and is provided with an auto-reload register (register R). Timer 2 data can be read using the TAB2 instruction and register R may be set as well as ready by means of the TRAB and TABR instructions respectively. Starting and stopping the counter as well as the selection of the source (prescaler or external input from port T) is controlled by the timer control registers. In addition, when port T has been chosen as the source, if only timer 1 is counting, gating is possible by means of using counter enabling controlled by the timer control registers. The overflow condition results in the setting of the flag 2F, after which timer 2 can be set with data once more by register R (auto-reload register) and continue counting.

(3) Prescaler

The overflow time can be selected as either 160μs or 1270μs (when using a 600kHz clock frequency) by means of the counter control registers.

(4) Timer I/O port T

This port can be selected by the counter control register as the source for timer 2. In addition, when another source has been selected, a pulse is available at this port every time timer 2 reaches the overflow condition.

(5) Timer 1 and 2 overflow flags 1F and 2F

These flags are set when the corresponding timer has reached the overflow condition. To test these flags, generation of an interrupt and skip instructions (SNZ1, SNZ2) can be used. The selection of which will be used is made by the timer control registers. By using either, these flags will be reset.

(6) Timer control registers V and W

The timer control registers are used to perform the above described control functions. Instructions TVA and TWA are used to transfer control data to these register.

Input/Output Ports

(1) Port K (K₇~K₀)

This analog/digital input port is capable of 8-bit input using the SZJ instruction and two groups of 4-bit inputs using the IAS i instruction. The analog signal may be A/D converted using either successive approximation or sequential comparison, as determined by the program. Also, an arbitrary threshold level in the range 0~7V with respect to the digital signal may be input, enabling the use of the port as a high-noise immunity input.

Pull-down transistors and discharge transistors (for use

with capacity touch-type keys) may be selected as mask options.

(2) Port D (D₁₁~D₀)

This port consists of 12 bits which can be used for both input and output functions by means of the SZD, SD, and RD instructions. The output section provides individual bit latching and the contents of register Y can be used to designate a single bit of port D for output or sensing. When using the port for input, the output must be cleared to 0 first. The instructions CLD and CLDS can be used to clear all bits of the port to 0. The outputs are open-drain circuits which can be provided with pull-down transistors as a mask option.

(3) Port F (F₃~F₀)

This 4-bit port is controlled for output and input by the OFA and IAF instructions respectively. When using a bit for input, that bit output must first be set to 0. The outputs are open drain circuits.

(4) Port S (S₇~S₀)

This port can perform 8-bit output using the OSAB, OSPA, and OSE instructions and 4-bit input using the IAS i instruction.

A built-in S output PLA has been provided which can code 4 bits of register A data arbitrarily and provide output using the OSPA instruction. The PLA output coding is a mask option.

When the port is used for input, the outputs must first be set to 0. All the port S bits may be set to 0 by means of the CLS or CLDS instructions.

The outputs are open-drain circuits which can be provided with pull-down transistors as a mask option.

V_P Pin

This pin is used to supply the required voltage for the port D and port S pull-down transistors. Built-in pull-down transistors can be provided as a mask option for driving

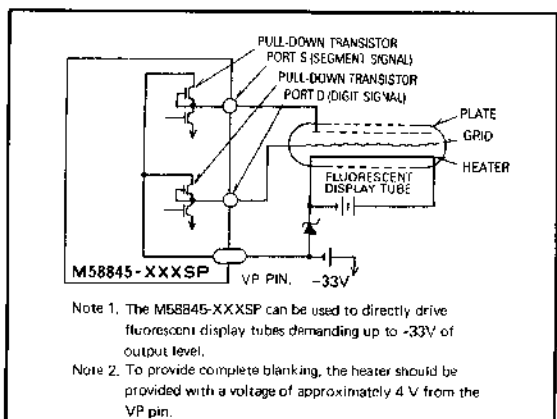

Fig. 5 Fluorescent display tube drive circuit

**SINGLE-CHIP 4-BIT MICROCOMPUTER
 WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER**

fluorescent display tubes, as shown in Fig. 5, eliminating the need for the usual externally connected pull-down resistors and resulting in a reduction in the number of system components.

Reset

When the RESET pin is kept high for at least 3 machine cycles, the reset state is enabled. After reset has been performed, when the RESET input is driven low, program execution will begin at page 0, address 0.

When the reset state is enabled, the following operations are performed.

- (1) The program counter is set to 0, address 0, (PC) ← 0
- (2) The interrupt mode is in the disabled state. INTE ← 0 (the same as for the execution of the DI instruction)
- (3) The carry and data pointer selector is set to 0, specifying DP and CY.
- (4) Registers V and W are set to 0. V=W ← 0₁₆
- (5) The 3 interrupt flags, external interrupt flag (EXF), timer 1 overflow flag (1F), and timer 2 overflow flag (2F) are reset. EXF=1F=2F ← 0
- (6) All outputs of port D are cleared to low (D) ← 0
- (7) All outputs of port F are cleared to low (F) ← 0
- (8) All outputs of port S are cleared to low (S) ← 0
- (9) All outputs of port T are cleared to low (T) ← 0

Clock Generator Circuits

A clock generator circuit has been built in, to allow control of the frequency by means of an externally connected RC circuit or ceramic resonator. In addition, an external clock signal may be applied at the X_{IN} pin, leaving the X_{OUT} pin open. Circuit examples are shown in Fig. 6~8.

Fig. 6 External RC circuit

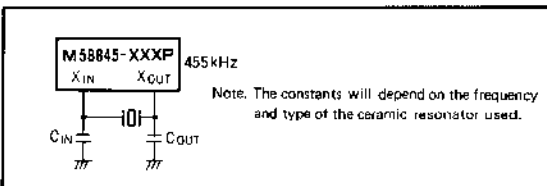

Fig. 7 Externally connected ceramic resonator

Fig. 8 External clock input circuit

Mask Options

The following mask options are available, specifiable at the time of initial ordering.

- (1) S output PLA data
- (2) Port K (K₇~K₀) discharge transistors
- (3) Port K (K₇~K₀) pull-down transistors
- (4) Port D (D₁₁~D₀) pull-down transistors
- (5) Port S (S₇~S₀) pull-down transistors
- (6) Selection of interrupt input TTL-compatible Schmitt circuits
- (7) Selection of RESET input TTL-compatible Schmitt circuits
- (8) Selection of port T TTL-compatible Schmitt circuits

Documentation Required upon Ordering

The following information should be provided when ordering a custom mask.

- (1) M58845-XXXSP mask confirmation sheet
- (2) ROM data 3 EPROM sets
- (3) S output PLA coding On confirmation sheets
- (4) Port K input discharge transistors On confirmation sheets
- (5) Port K pull-down transistors
- (6) Port D pull-down transistors
- (7) Port S pull-down transistors
- (8) Selection of interrupt input TTL-compatible Schmitt circuits
- (9) Selection RESET input TTL-compatible Schmitt circuits
- (10) Selection of Port T input TTL-compatible Schmitt circuits

MACHINE INSTRUCTIONS

Type of instruction	Mnemonic	Instruction code				No. of words	No. of cycles	Functions	Skip conditions	Flag CY	Description of operation					
		D ₇	D ₆	D ₅	D ₄							D ₃	D ₂	D ₁	D ₀	
Register-to-register transfers	TAB	0	0	0	0	1	1	1	—	X	Transfers contents of register B to register A.					
	TBA	0	0	0	0	1	1	0	—	X	Transfers contents of register A to register B.					
	TAY	0	0	0	0	1	1	0	—	X	Transfers contents of register Y to register A.					
	TYA	0	0	0	0	1	1	0	—	X	Transfers contents of register A to register Y.					
	TEAB	0	0	0	0	1	1	0	—	X	Transfer contents of registers A and B to register E.					
TEPA	0	0	0	0	1	1	0	1	—	X	Decodes contents of register A in the PLA and transfers result to register E.					
RAM addresses	LXY A, Y	0	1	x	x	y	y	0	CY + x	—	X	Loads value of "x" into register X, and of "y" into Y. When LXY is written successively the first is executed and successive ones are skipped.				
	LZ z	0	0	1	0	0	1	0	4A + z	—	X	Loads value of "z" into register Z.				
	INY	0	0	0	0	0	0	0	0	2	—	X	Increments contents of register Y by 1. Skips next instruction when new contents of register Y are "0".			
	DEY	0	0	0	0	0	0	0	1	3	—	X	Decrements contents of register Y by 1. Skips next instruction when new contents of register Y are "15".			
LCPS i	0	0	1	0	0	0	0	0	4i	—	X	Transfers designated contents of register J to register A.				
RAM-accumulator transfers	TAM j	0	0	1	1	0	1	1	0	64 + j	—	X	Transfers the RAM contents addressed by the active DP to register A. Register X is then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X.			
	XAM j	0	0	1	1	0	0	1	0	6j	—	X	Exchanges the contents of the RAM DP and register A. Contents of X are then "exclusive OR-ed" with the value j, and the result stored in register X.			
	XAMD j	0	0	1	1	0	1	0	6	8j + j	Y=15	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X. The contents of register Y are decremented by 1, and when the result is 15, the next instruction is skipped.			
	XAM j	0	0	1	1	0	1	1	1	6C + j	Y=0 Y=masked skip condition	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction and result stored in register X. The contents of register Y are incremented by 1, and when the result meets the next instruction is skipped with the marked skip condition.			
Arithmetic operations	LA n	0	1	0	1	n	n	0	B	n	—	Written successively	X	Loads the value n into register A. When LA is written consecutively the first is executed, and successive ones are skipped.		
	AM A	0	0	0	0	0	1	0	0	A	—	—	X	Adds the contents of the RAM to register A. The result is retained in register A, and the contents of flag CY are unaffected.		
	AMC	0	0	1	0	0	0	1	1	4	3	—	—	0	Adds the RAM contents addressed by the active DP and contents of flag CY to register A. The result is stored in register A and the carry in the active flag CY.	
	AMCS	0	0	1	0	1	0	0	1	5	3	—	—	0	Adds the contents of the RAM and flag CY to register A. The result is stored in register A and the carry in the active flag CY.	
	A n	0	1	0	1	n	n	n	0	A	n	A carry is not produced and n=6	—	X	Adds value n in the instruction to register A. The contents of flag CY are unaffected and their next instruction is skipped if a carry is not produced, except when n=6.	
	SC	0	0	1	0	0	0	0	0	4	9	—	—	1	Sets active flag CY.	
	RC	0	0	1	0	0	0	0	0	4	8	—	—	0	Resets active flag CY.	
SZC	0	0	0	0	1	1	1	1	0	2	F	—	—	0	Sets skip condition when contents of the active flag CY are 0.	
CMA	0	0	0	0	1	1	1	1	0	2	F	—	—	X	Stores complement of register A in register A.	
Bit operations	SB j	0	0	1	0	0	1	1	0	4C + j	—	—	—	X	Sets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	RB j	0	0	1	0	1	1	1	0	5C + j	—	—	—	X	Resets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	SZB i	0	0	0	1	0	0	1	1	2	i	—	—	X	Skip next instruction when the contents of the jth bit of the RAM addressed by the active DP (the bit which is designated by the value j in the instruction) are 0.	
Compares	SEAM	0	0	0	1	0	0	1	1	0	2	6	—	—	X	Skip next instruction when contents of register A are equal to the RAM contents addressed by the active DP.
	SEY y	0	0	0	1	1	y	y	0	3	y	—	—	X	Skip next instruction when the contents of register Y are equal to the value y in the instruction.	
A/D converter operations	TLA	0	0	0	0	1	1	0	0	1	9	—	—	X	Transfers contents of register A to register L.	
	THA	0	0	1	0	1	1	0	0	5	9	—	—	X	Transfers contents of register A to register H.	
	XAL	0	0	0	0	1	1	0	0	1	8	—	—	X	Exchanges contents of register A with contents of register L.	
	XAH	0	0	1	0	1	1	0	0	5	8	—	—	X	Exchanges contents of register A with contents of register H.	
	LC7	0	0	1	0	1	1	1	1	0	7	—	—	X	Loads 7 to register C.	
	DEC	0	0	0	0	0	1	0	0	1	1	—	—	X	Decrements contents of register C by 1, when result is 7, skips.	
SHL	0	0	1	0	0	0	0	1	0	4	2	—	—	X	Sets the bit in register L or H designated by register C. The box instruction shows the relationship between register C and bit position.	
RHL	0	0	1	0	1	0	0	1	0	5	2	—	—	X	Resets the bit in register L or H that is designated by register C.	
CPA	0	0	0	0	0	0	1	0	0	0	8	—	—	X	Reads all analog values from input port K for comparison with D-A converter output V _{ref} , and either sets the respective bit of register J to the next instruction cycle, wherever V _{ref} > V _{K(i)} is true, or resets it, wherever V _{ref} < V _{K(i)} is true.	
CPAS	0	0	1	0	1	0	0	0	0	1	5	—	—	X	Reads and stores temporarily all analog values from input port K, which are then unaffected by changes in port K inputs. These values are compared with the D-A converter output V _{ref} , calculated from contents of registers H and L, and respective bits of register J are set/reset. Repeated when contents of registers H-L are changed.	

MITSUBISHI MICROCOMPUTERS M58845-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER

4

Type of instruction	Mnemonic	Instruction code		16-bit notation	No. of words	No. of cycles	Functions	Skip conditions	Flag CY	Description of operation
		D ₇ D ₆ D ₅ D ₄ D ₃ D ₂ D ₁ D ₀	D ₇ D ₆ D ₅ D ₄ D ₃ D ₂ D ₁ D ₀							
A/D converter operations	CPAE	0 0 1 0 1 0 0 0 0	0 5 0		1	1	Execution of the instruction CPAS is over, and no more changes will made in (Y).	—	X	Terminates execution of instruction CPAS. Contents of register J remain unaffected, maintaining the value immediately before termination, and input port K is again ready to receive input.
	TAJ	0 0 0 0 0 1 1 0 1	0 0 0		1	1	(Y ₀)=0 when: (A) ₇ =(J ₇ J ₆ J ₅ J ₄) (Y ₀)=1 when: (A) ₇ =(J ₆ J ₅ J ₄ J ₃)	—	X	
	SZJ	0 0 0 1 0 1 0 0 1	0 2 9		1	1		(J(Y))=0	X	Skips next instruction when the bit in register J, designated by register Y, is 0.
Timer operation	T1AB	0 1 0 0 0 0 1 0 0	0 8 4		1	1	(T ₁ T ₀)←(B) (T ₃ T ₂)←(A)	—	X	Transfers contents of register A and register B to timer 1.
	TRAB	0 1 0 0 0 0 1 0 1	0 8 5		1	1	(T ₃ T ₂)←(A) (T ₁ T ₀)←(B)	—	X	Transfers contents of register A and register B to timer 2 auto reload register R.
	TAB1	0 1 0 0 0 1 0 0 0	0 8 8		1	1	(T ₃ T ₂)←(A) (T ₁ T ₀)←(B)	—	X	Transfers contents of timer 1 to register A and register B.
	TADR	0 1 0 0 0 1 0 0 1	0 8 9		1	1	(T ₃ T ₂)←(A) (T ₁ T ₀)←(B)	—	X	Transfers contents of timer 1 auto reload register R to register A and register B.
	TAB2	0 1 0 0 0 1 0 1 0	0 8 A		1	1	(T ₃ T ₂)←(A) (T ₁ T ₀)←(B)	—	X	Transfers contents of timer 2 to register A and register B.
	TVA	0 1 0 0 0 1 1 1 0	0 8 B		1	1	(V) ₇ ←(A)	—	X	Transfers contents of register A to timer control register V.
	TWA	0 1 0 0 0 1 1 1 1	0 8 7		1	1	(W) ₇ ←(A)	—	X	Transfers contents of register A to timer control register W.
	SNZ1	0 1 0 0 0 0 0 1 0	0 8 2		1	1		(+F)=1	X	Skips the next instruction if flag 1F is 1.
SNZ2	0 1 0 0 0 0 0 1 1	0 8 3		1	1		(2F)=1	X	Skips the next instruction if flag 2F is 1.	
Branch	B xy	1 1 x x x y y y y	1 8 y		1	1	(PC) ₇ ←16x+y (PC) ₆ ←3, (PC) ₅ ←16x+y	—	X	Jumps to address xy of the current page.
	BL pxy	0 0 1 1 1 P P P P 1 1 x x x y y y y	0 7 P 1 8 y		2	2	(PC) ₇ ←p (PC) ₆ ←16x+y	—	X	Jumps to address xy of page p.
	BA xy	0 0 0 0 0 0 0 1 1 1 x x x x x x x	0 0 1 1 8 X		2	2	(PC) ₇ ←16x+(A) (PC) ₆ ←3, (PC) ₅ ←16x+(A)	—	X	Subroutine on the current page. Exchange the lower 4 bits of the contents of address x with the contents of register A and branch to address 16x+A. Page 3 subroutine: After execution of a BM or BMA instruction without execution of a RT, RTS, BL, BML, BLA, or BMLA instruction, when a BA instruction is executed branching is done to address 16x+(A) on page 3.
	BLA pxy	0 0 0 0 0 0 0 1 0 0 1 1 1 P P P P 1 1 x x x x x x x	0 0 1 0 7 P 1 8 X		3	3	(PC) ₇ ←p (PC) ₆ ←16x+(A)	—	X	Subroutine on a different page: Exchange the lower 4 bits of the contents of address x with the contents of register A and branch to the address 16x+(A).
	BM xy	1 0 x x x y y y y	1 x y		1	1	(SK) ₇ ←(SK) ₆ ←(SK) ₅ ←(PC) ₇ (PC) ₆ ←2, (PC) ₅ ←16x+y (PC) ₄ ←2, (PC) ₃ ←16x+y	—	X	Calls for the subroutine starting at address x(A) of page 2. Jumps to address xy of page 2 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
Subroutine calls	BML pxy	0 0 1 1 1 P P P P 1 0 x x x y y y y	0 7 P 1 x y		2	2	(SK) ₇ ←(SK) ₆ ←(SK) ₅ ←(PC) ₇ (PC) ₆ ←p, (PC) ₅ ←16x+y	—	X	Calls for the subroutine starting at address xy of page p.
	BMA xx	0 0 0 0 0 0 0 1 1 0 x x x x x x x	0 0 1 1 x x		2	2	(SK) ₇ ←(SK) ₆ ←(SK) ₅ ←(PC) ₇ (PC) ₆ ←2, (PC) ₅ ←16x+(A)	—	X	Calls for the subroutine starting at address x(A) of page 2. Jumps to address x(A) of page 2 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
	BMLA pxx	0 0 0 0 0 0 0 1 0 0 1 1 1 P P P P 1 0 x x x x x x x	0 0 1 0 7 P 1 x x		3	3	(SK) ₇ ←(SK) ₆ ←(SK) ₅ ←(PC) ₇ (PC) ₆ ←p, (PC) ₅ ←16x+(A)	—	X	Calls for the subroutine starting at address x(A) of page p.
	RTI	0 0 1 0 0 0 1 1 0	0 4 6		1	1	(PC) ₇ ←(SK) ₆ ←(SK) ₅ ←(SK) ₂	—	X	Returns from interrupt routine to main routine. The internal flip-flops returned to the value held immediately before the interrupt.
Program returns	RT	0 0 1 0 0 0 1 0 0	0 4 4		1	1	(PC) ₇ ←(SK) ₆ ←(SK) ₅ ←(SK) ₂	—	X	Returns to the main routine from the subroutine.
	RTS	0 0 1 0 0 0 1 0 1	0 4 5		1	1	(PC) ₇ ←(SK) ₆ ←(SK) ₅ ←(SK) ₂	—	X	Returns to the main routine from the subroutine, and unconditionally skips the next instruction.
Input/output	CLD	0 0 0 0 1 0 0 1 1	0 1 3		1	1	(D) ₇ ←0	—	X	Clears port D (low level output).
	CLS	0 0 0 0 1 0 0 0 0	0 1 0		1	1	(S) ₇ ←0	—	X	Clears port S.
	CLD6	0 0 0 0 1 0 0 0 1	0 1 1		1	1	(D) ₆ ←0	—	X	Clears ports S and D.
	SD	0 0 0 0 1 0 1 0 1	0 1 5		1	1	(D(Y))←1 where, Y=0-11	—	X	Sets the bit of port D that is designated by register Y.
	RD	0 0 0 0 1 0 1 0 0	0 1 4		1	1	(D(Y))←0 where, Y=0-11	—	X	Resets the bit of port D that is designated by register Y.
	SZD	0 0 0 1 0 1 0 1 1	0 2 B		1	1		(D(Y))=0 where, Y=0-11	X	Skips the next instruction if the contents of the bit of port D that is designated by register Y are 0.
	OSAB	0 0 0 0 1 0 1 1 1	0 1 B		1	1	(S) ₇ ←(S) ₆ ←(B) (S) ₅ ←(S) ₄ ←(A)	—	X	Output contents of registers A and B to port S.
	OSPA	0 0 0 0 1 0 1 1 1	0 1 7		1	1	(S) ₇ ←(S) ₆ ←through PLA←(A)	—	X	Decodes contents of register A by PLA and the result is output to ports.
	OSE	0 0 0 0 0 1 0 1 1	0 0 B		1	1	(S) ₇ ←(F)	—	X	Outputs contents of register F to port S.
	IAS 1	0 0 1 0 1 0 1 0 1	0 5 4		1	1	i=0(A) ₇ ←(S) ₇ ←(S) ₆ i=1(A) ₆ ←(S) ₇ ←(S) ₆	—	X	Transfers from port S to register A. The high-order four bits of port S are transferred when the value of i in the instruction is 0 or the low-order four bits are transferred when the value of i is 1.
Misc. Interrupts	OFA	0 1 0 0 0 0 0 0 1	0 8 1		1	1	(+) ₇ ←(A)	—	X	Sets interrupt flag INTE to enable interrupts.
	IAF	0 1 0 0 0 1 1 0 0	0 8 C		1	1	(A) ₇ ←(F)	—	X	Resets interrupt flag INTE to disable interrupts.
Misc. Interrupts	EI	0 0 0 0 0 0 1 0 1	0 0 5		1	1	(INTE)←1	—	X	Outputs contents of register A to port F.
	DI	0 0 0 0 0 0 1 0 0	0 0 4		1	1	(INTE)←0	—	X	Transfers input from port F to register A.
	NOP	0 0 0 0 0 0 0 0 0	0 0 0		1	1	(PC) ₇ ←(PC) ₆ ←1	—	X	No operation.

SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER

Symbol	Contents	Symbol	Contents	Symbol	Contents
A	4-bit register (accumulator)	SK ₀	11-bit stack register	—	Shows direction of data flow
B	4-bit register	SK ₁	11-bit stack register	(;	Indicates contents of register, memory, etc.
C	3-bit register	SK ₂	11-bit stack register	xx	2-bit binary variable
E	8-bit register	T ₁	Timer 1	yyyy	4-bit binary variable
H	4-bit register	T ₂	Timer 2	z	1-bit binary variable
J	8-bit register	CY	1-bit carry flag	mm	4-bit binary variable
L	4-bit register	INTE	Interrupt enable flag	i	1-bit binary constant
R	8-bit timer 2 auto-reload register	OP _S	Indicates which data pointer and carry are active	ii	2-bit binary constant
U	4-bit register	OF	1-bit timer 1 overflow flag	XXXX	4-bit unknown binary number
W	4-bit register	OF	1-bit timer 2 overflow flag	or	Exclusive-OR
X	2-bit register	EXF	1-bit external interrupt flag	—	Negation
Y	4-bit register	D	12-bit port	X	Indicates flag is unaffected by instruction execution
Z	1-bit register	F	4-bit port	yy	Label used to indicate the address XXXYYYY
DP	7-bit data pointer, combination of registers X, Y, and Z	K	8-bit port	zzy	Label used to indicate the address XXXZZYY of page PEPP
PC _H	The high-order 4-bits of the program counter	S	8-bit port	C +	Hexadecimal number C + binary number +
PC _L	The low-order 7-bits of the program counter	T	1-bit port	r	
PC	11-bit program counter, combination of PC _H and PC _L	INT	1-bit interrupt request signal		

Note 1. When a skip has occurred, the next instruction only is ignored and the program counter is not incremented by 2, therefore, the number of cycles does not change in accordance with the existence or non-existence of skip

MITSUBISHI MICROCOMPUTERS M58845-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH 8-BIT A/D CONVERTER AND TWO TIMER/EVENT COUNTER

Note 1: This list shows the machine codes and corresponding machine instructions. $D_3 \sim D_0$ indicate the low-order 4 bits of the machine code and $D_8 \sim D_4$ indicate the high-order 5 bits. Hexadecimal numbers are also shown that represent the codes. An instruction may consist of one, two, or three words, but only the first word is listed. Code combination indicated with a bar (-) must not be used.

Note 2: Two-word instruction

	Second word
BL	1 1xxx yyy
BML	1 0xxx yyy
BA	1 1xxx XXXX
BMA	1 0xxx XXXX

Three-word instruction

	Second word	Third word
BLA	0 0111 pppp	1 1xxx XXXX
BM	0 0111 pppp	1 0xxx XXXX

Note 3: Relationships between branching and page by means of branching instructions and subroutine calling instructions.

4

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V_{DD}	Supply voltage	With respect to V_{SS}	0.3 ~ -20	V
V_I	Input voltage (ports D and S, and input VP)		0.3 ~ -35	V
V_I	Input voltage, inputs other than ports D and S, and input VP		0.3 ~ -20	V
V_O	Output voltage, ports D and S		0.3 ~ -35	V
V_O	Output voltage, other outputs than ports D and S		0.3 ~ -20	V
P_d	Power dissipation	$T_a = 25^\circ\text{C}$	1100	mW
T_{opr}	Operating temperature		-10 ~ 70	$^\circ\text{C}$
T_{sig}	Storage temperature		-40 ~ 125	$^\circ\text{C}$

RECOMMENDED OPERATING CONDITIONS ($T_a = -10 \sim 70^\circ\text{C}$, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V_{DD}	Supply voltage	-13.5	-15	-16.5	V
V_{SS}	Supply voltage		0		V
V_p	Pull-down transistor supply voltage	0		-33	V
V_{IH}	High-level input voltage	-1.5		0	V
$V_{IH}(\phi)$	High-level clock input voltage	-1.5		0	V
V_{IL}	Low-level input voltage, inputs other than ports D and S	V_{DD}		-4.2	V

I _{I(φ)}	Clock input current	V _{I(φ)} = -15V, Ta = 25°C		-20	-40	μA
I _{OH}	High-level output current, port D (Note 2)	V _{DD} = -15V, V _{OH} = -25V, Ta = 25°C			-15	mA
I _{OH}	High-level output current, ports S and F	V _{DD} = -15V, V _{OH} = -25V, Ta = 25°C			-6 (port F) -8 (port S)	mA
I _{OL}	Low-level output current, ports D and S	V _{OL} = -33V, Ta = 25°C			-33	μA
I _{OL}	Low-level output current, port F	V _{DD} = -15V, Ta = 25°C			-33	μA
I _{DD}	Supply current	V _{DD} = -15V, Ta = 25°C		21		mA
I _{REF}	Reference supply current	V _{REF} = -7V, Ta = 25°C			-1	mA
C _I	Input capacitance, port K	V _{DD} = V _I = V _O = V _{SS} , f = 1MHz, 25mVrms		7	10	pF
C _{I(φ)}	Clock input capacitance	V _{DD} = X _{OUT} = V _{SS} , f = 1MHz, 25mVrms		7	10	pF
	A-D conversion linearity error	V _{REF} = -7V	Overall	± 2	± 3	LSB
	A-D conversion zero error					
	A-D conversion fullscale error					

Note 1. Currents are taken as positive when flowing into the IC (zero signal condition), with the minimum and maximum values as absolute values.
 2. It is possible to connect up to 5 lines of the port D at maximum ratings (-15mA) or all lines of port S and F at maximum ratings of -8mA and -6mA respectively.

BASIC TIMING DIAGRAM

Note 3. The crosshatched area indicates invalid input.

MITSUBISHI MICROCOMPUTER M58846-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH TWO TIMER/EVENT COUNTER

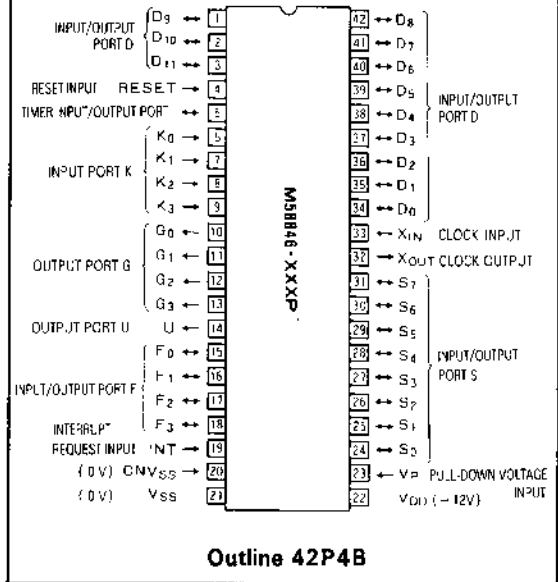

DESCRIPTION

The M58846-XXXSP is a single-chip 4-bit microcomputer developed using p-channel aluminum gate ED-MOS technology. The device includes two timers (one 7-bit timer and one 8-bit timer/event counter). It is housed in a 42-pin shrink plastic molded DIL package.

FEATURES

- Basic machine instructions 65
- Basic instruction execution time (1-word instruction at a clock frequency of 600kHz) 10 μ s
- Memory capacity ROM: 2048 words x 9 bits
RAM: 128 words x 4 bits
- Single -12V power supply
- Two built-in timers (timer 1: 7-bit timer/counter, timer 2: 8-bit timer/event counter) 2 lines
- Interrupt function
3 factors (external, timer 1, timer 2), 1 level
- Two built-in data pointers
- Subroutine nesting 3 levels
- Input (port K) 4 lines
- Input/output (ports D, F, and S) 24 lines
- Output (ports G and U) 5 lines
- Timer input/output (port T) 1 line
- Direct drive for large fluorescent display tubes is possible
- Built-in decoder PLA for port S outputs (mask option)
- Built-in pull-down transistors (ports D, K, and S mask option)
- Built-in clock generator circuit

PIN CONFIGURATION (TOP VIEW)

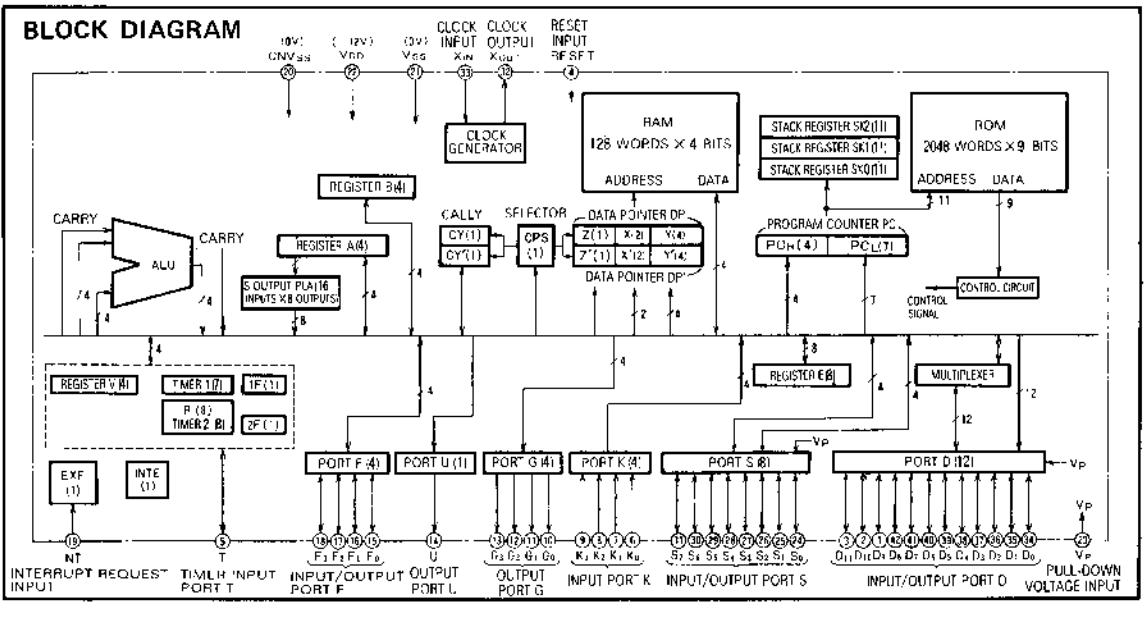

4

APPLICATIONS

- VTRs, TVs, cassette decks
- Office equipment, copying machines, medical equipment
- Educational equipment, games

**SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH TWO TIMER/EVENT COUNTER**

PIN DESCRIPTION

Pin	Name	Input or output	Function
V _{SS}	Ground		Connected to 0V potential
V _{DD}	Supply voltage		Connected to a +12V supply
V _E	Pull-down supply	In	Input for the supply voltage connected to the load resistors (mask option) for ports D and S
K ₃ ~ K ₀	Input port K	In	This port can be used to perform 4-bit TTL-compatible or Schmitt input. Pull-down transistors and input discharge transistors are available as mask options.
D ₁₁ ~ D ₀	I/O port D	In/out	Port D consists of a 12-bit input/output port, all bits operating individually. When a port D output is programmed low, the output floats and the input signal can be sensed. The outputs are open drain circuits which can be provided with pull-down transistors as a mask option.
F ₃ ~ F ₀	I/O port F	In/out	Port F is a 4-bit input/output port. When the output is programmed to low, the output floats and the input signal can be sensed. The output circuits are open drain circuits.
S ₇ ~ S ₀	I/O port S	In/out	The I/O port S can be used as either an 8-bit output port or a pair of 4 bit input ports. When the output port S is programmed to the low level, it remains in the floating state so that it can be used as an input port.
G ₃ ~ G ₀	Output port G	Out	This is a 4-bit output port.
U	Output port U	Out	This is a 1-bit output port.
T	Timer I/O port T	In/out	This port is used as the timer 2 event counter input and the timer 2 overflow output, the functions being software selectable.
INT	Interrupt request input	In	This is the input for interrupt requests.
RESET	Reset	In	When this input is kept high for at least 3 machine cycles, the reset state is enabled.
X _{IN}	Clock input	In	These are the input and output pins for the built-in clock generator. A ceramic filter element (300kHz ~ 600kHz) or a resistor/capacitor combination are connected to these pins to provide the required oscillation stability.
X _{OUT}	Clock output	Out	
CV _{SS}	CV _{SS}	In	This input is connected to V _{SS} and must have a high-level input applied to it (0V).

MITSUBISHI MICROCOMPUTER
M58846-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH TWO TIMER/EVENT COUNTER

BASIC FUNCTION BLOCKS

Program Memory (ROM)

This 2048-word x 9-bit Mask ROM can be programmed with machine instruction codes in accordance with the customer's specifications. It consists of 16 pages, each containing an address range of 0~127. Fig. 1 shows the address map for this ROM.

Program Counter (PC)

This counter is used to specify ROM addresses and the sequence of read-out of instructions stored in ROM. The program counter is an 11-bit counter, the upper-order 4 bits of which (PC_H) indicate the ROM page, and the lower 7 bits of which (PC_L) are a pure binary address designation. Each time an instruction is executed, PC_L is incremented by 1 step. For branching and subroutine call instructions, its value is set to the designated address.

When the 127 address is reached for every page, the address value returns to the first address of that page. Therefore, for moving from one page to another page, the page byte itself must be modified. This is done using the **BL** and **BLA** instructions.

Page 2 and page 3 are special pages used for subroutine calls. Page 2 can be called with a 1-word instruction from any arbitrary page. This instruction is either **BM** or **BMA**. When either **BM** or **BMA** is executed, subsequent **BM** or **BMA** instructions are equivalent to **B** and **BA** on page 2. Also, **B** or **BA** is equivalent to **B** or **BA** on page 3. This condition is cancelled when the **RT**, **RTS**, **BL**, **BML**, **BLA**, or **BMLA** instruction is executed. Note 3 shows the instruction codes and corresponding states.

Stack Registers (SK₀, SK₁, SK₂)

These registers are used to temporarily store the contents of the PC while executing subroutines or interrupt programs until the program returns to its original routine. The SK registers are organized in 3 words of 11 bits each, enabling up to 3 levels of subroutine nesting. If 1 level is used for an interrupt routine, the remaining 2 levels can be used for subroutine calls.

Data Memory (RAM)

This 512-bit (128 words x 4 bits) RAM is used to store both processing and control data. One RAM word consists of 4 bits with bit manipulation possible over the entire storage area. The 128 words are arranged as 2 file groups x 4 files x 16 digits x 4 bits. Fig. 2 shows the RAM address map. The RAM address specification is made by the combination of data pointer DP register Z, register X, and register Y. Thus, the selector CPS and data pointer DP must be set. However, as long as the address is not changed this is not necessary.

Data Pointers (DP, DP')

These registers are used to designate the RAM address, and bit position for the I/O port D and register J. Each data pointer is composed of a 7-bit register. Register Z (the most significant bit of DP) designates the RAM file group; register X (the central 2 bits) designates the RAM file; and register Y (the least significant 4 bits) designates the digit position of the RAM file. At the same time, register Y designates the bit positions of the I/O port D.J.

4-Bit Arithmetic Logic Unit (ALU)

This unit executes 4-bit arithmetic and logical operations by means of a 4-bit adder and related logic circuitry.

Register A and Carry Flag (CY)

Register A is a 4-bit accumulator that constitutes the basis for arithmetic operations. Data processing operations such as arithmetic and logical operations, data transfer, exchange, conversion, and data input/output are executed by means of this register. The carry flag CY is used to store carry or overflow after execution of arithmetic and logical operations by the arithmetic logic unit. The carry flag may also be used as a 1-bit flag. Two carry flags, CY and CY', are available and selected by selector CPS, as is the data pointer DP.

Registers B and E

Register B is composed of 4 bits and can be used as a 4-bit temporary storage register or for 8-bit data transfer in conjunction with register A. Register E is composed of 8 bits and is used not only as an 8-bit temporary storage register, but also as a temporary for the I/O port S.

Interrupt Functions

The M58846-XXXSP provides 3-factor, 1-level vector interrupt capability, enabling unique branching addresses for each interrupt factor.

Interrupt factor		Interrupt address
Interrupt type	Causal condition	
External interrupt	Rising edge at the INT input pin	Page 1, address 0
Timer 1 interrupt	Timer 1 overflow	Page 1, address 2
Timer 2 interrupt	Timer 2 overflow	Page 1, address 4

Fig. 3 Vector Interrupt Addresses

The interrupt vector addresses are shown in Fig. 1.

An interrupt is generated whenever any of the casual conditions listed in Fig. 3 are satisfied at a time when the INTE flag is set to 1 (when the EI instruction is executed the INTE flag is set to 1, enabling interrupt; the DI instruction clears this flag to 0, prohibiting interrupts). If any of the interrupt causing conditions continues when the INTE flag is 0, an interrupt is generated when the INTE flag is set to 1.

The interrupts generated as a result of timer 1 and timer 2 overflow conditions can be software controlled, allowing confirmation of the overflow condition using a skip instruction.

When an interrupt program is used, one level of the three-level stack register is required, the remaining two levels being used for subroutines. After the interrupt program is started, the data pointer DP, register A, carry flag CY, and registers used by the interrupt program are saved. The instruction RTI is required to restore these before returning to the main program.

When an interrupt occurs, the microcomputer internal states are as follows.

(1) Program counter

The current address in the main program is stored in a stack register and the vector interrupt address as shown in Fig. 1 is loaded into the program counter.

(2) Interrupt flag INTE

The flag INTE is reset to disable further interrupts. This disabled state will continue even after return to the main program by the RTI instruction until the execution of an EI instruction.

(3) Skip flags

Skip flags are provided to discriminate skip instructions and consecutively described skip instructions. Each flag has its own stack within which the skip state is saved.

Timer/Event Counter (2 Lines)

The timer/event counter section consists of two lines (timers). As shown in Fig. 4, this section includes timer 1 and its overflow flag (1F) and timer 2 and its overflow register (register R), as well as the timer input/output port T and the timer control registers V and W.

Fig. 4 Timer/event counter block diagram

4

The two timers (timer 1 and 2) are controlled by means of the timer control registers.

(1) Timer 1

Timer 1 is implemented using a 7-bit counter which divides the machine cycle (100kHz for a 600kHz clock frequency) by 127, setting the flag 1F every time an overflow condition occurs.

The timer is ready to count after a system reset has occurred.

(2) Timer 2

Timer 2 is implemented using an 8-bit binary counter and is provided with an auto-reload register (register R). Timer 2 data can be read using the TAB2 instruction and register R may be set as well as read by means of the T2AB instruction. Starting and stopping the counter as well as the selection of the source (timer 1 or external input from port T) is controlled by the timer control registers. The overflow condition results in the setting of the flag 2F, after which timer 2 can be set with data once more by register R (auto-reload register) and continue counting.

(3) Timer I/O port T

This port can be selected by the counter control register as the source for timer 2. In addition, when another source has been selected, a pulse is available at this port every time timer 2 reaches the overflow condition.

(4) Timer 1 and 2 overflow flags 1F and 2F

These flags are set when the corresponding timer has reached the overflow condition. To test these flags, generation of an interrupt and skip instructions (SNZ1, SNZ2) can be used. The selection of which will be used is made by the timer control registers. By using either, these flags will be reset.

**SINGLE-CHIP 4-BIT MICROCOMPUTER
WITH TWO TIMER/EVENT COUNTER**

(5) Timer control registers V

The timer control register is used to perform the above described control functions. Instruction TVA is used to transfer control data to this register.

INPUT/OUTPUT PORTS

(1) Port K ($K_3 \sim K_0$)

This port is capable of performing 4-bit input by means of the IAK instruction or single-bit input by means of the SZK instruction.

The port K input circuits are TTL-compatible and may be provided with Schmitt circuits as a mask option.

In addition, pull-down transistors may be provided as a mask option.

(2) Port D ($D_{11} \sim D_0$)

This port consists of 12 bits which can be used for both input and output functions by means of the SZD, SD, and RD instructions. The output section provides individual bit latching and the contents of register Y can be used to designate a single bit of port D for output. When using the port for input, the output must be cleared to 0 first. The instructions CLD and CLDS can be used to clear all bits of the port to 0.

The outputs are open-drain circuits which can be provided with pull-down transistors as a mask option.

(3) Port F ($F_3 \sim F_0$)

This 4-bit port is controlled for output and input by the OFA and IAF instructions respectively. When using a bit for input, that bit output must first be set to 0. The outputs are open-drain circuits.

(4) Port S ($S_7 \sim S_0$)

This port can perform 8-bit output using the OSAB, OSPA, and OSE instructions and 4-bit input using the IAS instruction.

A built-in S output PLA has been provided which can code 4 bits of register A data arbitrarily and provide output using the OSPA instruction. The PLA output coding is a mask option.

When the port is used for input, the outputs must first be set to 0. All the port S bits may be set to 0 by means of the CLS and CLDS instructions.

The outputs are open-drain circuits which can be provided with pull-down transistors as a mask option.

(5) Port G ($G_3 \sim G_0$)

This port can be used to perform 4-bit output by means of the OGA instruction. The outputs are open-drain circuits.

(6) Port U

This port can be used to perform 1-bit output by means of the SU and RU instructions. The outputs are open-drain circuits.

Vp PIN

This pin is used to supply the required voltage for the port D and port S pull-down transistors. Built-in pull-down transistors can be provided as a mask option for driving fluorescent display tubes, as shown in Fig. 5, eliminating the need for the usual externally connected pull-down resistors and resulting in a reduction in the number of system components.

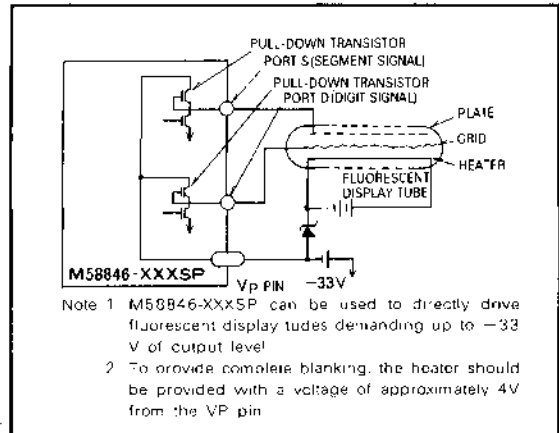

Fig.5 Fluorescent display tube drive circuit

RESET

When the RESET pin is kept high for at least 3 machine cycles, the reset state is enabled. After reset has been performed, when the RESET input is driven low, program execution will begin at page 0, address 0.

When the reset state is enabled, the following operations are performed.

- (1) The program counter is set to 0, address 0. $\{PC\} \leftarrow 0$
- (2) The interrupt mode is in the disabled state, $INTE \leftarrow 0$ (the same as for the execution of the DI instruction)
- (3) The carry and data pointer selector CPS is set to 0, specifying DP and CY.
- (4) Register V is set to 0. $V \leftarrow 0_{16}$
- (5) The 3 interrupt flags, external interrupt flag (EXF), timer 1 overflow flag (1F), and timer 2 overflow flag (2F) are reset. $EXF=1F=2F \leftarrow 0$
- (6) All outputs of ports D, F, S, G, U, and T are cleared to low $\{D\}=\{F\}=\{S\}=\{G\}=\{T\} \leftarrow 0$

CLOCK GENERATOR CIRCUIT

A clock generator circuit has been built in, to allow control of the frequency by means of an externally connected RC circuit or ceramic resonator. In addition, an external clock signal may be applied at the X_{IN} pin, leaving the X_{OUT} pin open. Circuit examples are shown in Fig. 6~8.

Fig. 6 External RC circuit

Fig. 7 Externally connected ceramic resonator

Fig. 8 External clock input circuit

MASK OPTIONS

The following mask options are available, specifiable at the time of initial ordering.

- (1) Port S output PLA data
- (2) Port K (K₃~K₀) pull-down transistors
- (3) Port D (D₁₁~D₀) pull-down transistors
- (4) Selection of port K input TTL-compatible Schmitt circuits
- (5) Selection of interrupt input TTL-compatible Schmitt circuits
- (6) Selection of RESET input TTL-compatible Schmitt circuits
- (7) Selection of port T TTL-compatible Schmitt circuits

4

DOCUMENTATION REQUIRED UPON ORDERING

The following information should be provided when ordering a custom mask

- (1) M58846 XXXSP mask confirmation sheet
- (2) ROM data 3 EPROM sets
- (3) Port S output PLA coding On confirmation sheets
- (4) Port K pull-down transistors
- (5) Port D pull-down transistors
- (6) Port S pull-down transistors
- (7) Selection of interrupt input TTL-compatible Schmitt circuits
- (8) Selection RESET input TTL-compatible Schmitt circuits
- (9) Selection of port T input TTL-compatible Schmitt circuits
- (10) Selection of port K input TTL-compatible Schmitt circuits

	TYA	0 0 0 0 0 1 1 1 0	0 0 C	1	1	(Y) ← (A)		X	Transfers contents of register A to register Y.
	TEAB	0 0 0 0 1 1 0 1 0	0 1 A	1	1	(E ₁ ← E ₂) ← (B) (E ₂ ← E ₀) ← (A) (E ₀ ← E ₀) ← (A)		X	Transfers contents of register A and B to register E.
RAM address	TEPA	0 0 0 0 1 0 1 1 0	0 1 S	1	1	(E ₁ ← E ₀) ← through PL _A ← (A)		X	Decodes contents of register A in the PLA and transfers result to register E.
	LXY x,y	0 1 1 x x y y y y	0 C y + x	1	1	(X) ← x where x = 0-3 (Y) ← y where y = 0-15	Written successively	X	Loads value of "x" into register X, and of "y" into Y. When LXY is written successively, the first is executed and successive ones are skipped.
	LZ z	0 0 1 0 0 1 0 1 z	0 4 A + z	1	1	(Y) ← z where z = 0-1		X	Loads value of "z" into register Z.
	INY	0 0 0 0 0 0 0 1 0	0 0 2	1	1	(Y) ← (Y) + 1	(Y) = 0	X	Increments contents of register Y by 1. Skips next instruction when new contents of register Y are "0".
	DEY	0 0 0 0 0 0 0 1 1	0 0 3	1	1	(Y) ← (Y) - 1	(Y) = 15	X	Decrements contents of register Y by 1. Skips next instruction when new contents of register Y are "15".
RAM accumulator	LCPS i	0 0 1 0 0 0 0 0 1	0 4 i	1	1	(CPS) ← i where i = 0-1		X	DP and CY are active when i = 0, DP and CY, when i = 1.
	TAM j	0 0 1 1 0 0 1 1 j	0 6 j + i	1	1	(A) ← (M(DP)) (X) ← (X) ∨, where i = 0-3		X	Transfers the RAM contents addressed by the active DP to register A. Register X is then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X.
	XAM i	0 0 1 1 0 0 0 1 i	0 6 i + j	1	1	(A) ← (M(DP)) (X) ← (X) ⊙, where i = 0-3		X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j, and the result stored in register X.
	XAMD j	0 0 1 1 0 1 0 1 j	0 6 j + i	1	1	(A) ← (M(DP)) (Y) ← (Y) - 1 (X) ← (X) ⊙, where i = 0-3	(Y) = 15	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X. The contents of register Y are decremented by 1, and when the result is 15, the next instruction is skipped.
Bit operations	XAM j	0 0 1 1 0 1 1 1 j	0 6 j + i	1	1	(A) ← (M(DP)) (Y) ← (Y) - 1 (X) ← (X) ⊙, where i = 0-3	(Y) = 0	X	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction and result stored in register X. The contents of register Y are incremented by 1, and when the result meets the next instruction is skipped with the marked skip condition.
	LA n	0 1 0 1 1 0 n n n	0 B n	1	1	(A) ← n where n = 0-15	Written successively	X	Loads the value n in to register A. When LA is written successively the first is executed, and successive ones are skipped.
	AM	0 0 0 0 0 1 0 1 0	0 0 A	1	1	(A) ← (A) + (M(DP))		X	Adds the contents of the RAM to register A. The result is retained in register A, and the contents of flag CY are unaffected.
	AMC	0 0 1 0 0 0 0 1 1	0 4 S	1	1	(A) ← (A) + (M(DP)) + (CY)		0/1	Adds the RAM contents addressed by the active DP and contents of flag CY to register A. The result is stored in register A, and the carry in the active flag CY.
Arithmetic operation	AMCS	0 0 1 0 1 0 0 1 1	0 5 S	1	1	(A) ← (A) + (M(DP)) + (CY) CY ← Carry	(CY) = 1	0/1	Adds the contents of the RAM and flag CY to register A. The result is stored in register A and the carry in the CY, but the next instruction is skipped when a carry is produced.
	A n	0 1 0 1 0 n n n n	0 A n	1	1	(A) ← (A) + n where n = 0-15	Carry = 0 where n = 6	X	Adds value n in the instruction to register A. The contents of flag CY are unaffected and their next instruction is skipped if a carry is not produced, except when n = 6.
	SC	0 0 1 0 0 1 0 0 1	0 4 9	1	1	(CY) ← 1		0	Sets active flag CY.
	RC	0 0 1 0 0 1 0 0 0	0 4 8	1	1	(CY) ← 0		0	Resets active flag CY.
	SZC	0 0 0 1 0 1 1 1 1	0 2 F	1	1	(CY) ← 0	(CY) = 0	X	Skips next instruction when contents of the active flag CY are 0.
	DMA	0 0 0 0 0 1 1 1 1	0 0 F	1	1	(A) ← (A)		X	Stores complement of register A in register A.
Compare	SB j	0 0 1 0 0 1 1 1 j	0 4 C + j	1	1	(M(DP)) ← 1 where i = 0-3		X	Sets the ith bit of the RAM (immediate field value) addressed by the active DP (the bit designated by the value j in the instruction).
	RB j	0 0 1 0 1 1 1 1 j	0 5 C + j	1	1	(M(DP)) ← 0 where i = 0-3		X	Resets the ith bit of the RAM (immediate field value) addressed by the active DP (the bit designated by the value j in the instruction).
	SZB j	0 0 0 1 0 0 0 1 j	0 2 i	1	1	(M(DP)) ← 0 where i = 0-3		X	Skips next instruction when the contents of the ith bit of the RAM (immediate field value) addressed by the active DP (the bit which is designated by the value j in the instruction) are 0.
Timer instruction	SEAM	0 0 0 1 0 0 1 1 0	0 2 6	1	1	(M(DP)) ← (A)		X	Skips next instruction when contents of register A are equal to the RAM contents addressed by the active DP.
	SEY y	0 0 0 1 1 y y y y	0 3 y	1	1	(Y) ← y where y = 0-15		X	Skips next instruction when the content of register Y are equal to the value y in the instruction.
A/D converter operations	T2AB	0 1 0 0 0 0 1 0 1	0 8 5	1	1	(R ₁ ← R ₁) + (B), (Z ₂ ← Z ₂) ← (B)		X	Transfers the contents of registers A and B to timer 2 and the read register.
	TAB2	0 1 0 0 0 1 0 1 0	0 8 A	1	1	(R ₁ ← R ₀) ← (A), (Z ₂ ← Z ₂) ← (A) (B) ← (Z ₁ - Z ₂) (A) ← (Z ₃ - Z ₂) (V) ← (A)		X	Transfers the contents of timer 2 to registers A and B
	TYA	0 1 0 0 0 0 1 1 0	0 8 5	1	1	(Y) ← (A)		X	Transfers the contents of register A to register Y
	SNZ1	0 1 0 0 0 0 0 1 0	0 8 2	1	1	(IF) ← 1		X	Skips the next instruction when the flag 1F is 1
	SNZ2	0 1 0 0 0 0 0 1 1	0 8 3	1	1	(ZF) ← 1		X	Skips the next instruction when the flag 2F is 1
A/D converter operations	B xy	1 1 x x x y y y y	1 8 y + x	1	1	(PC _L) ← 16x + y (PC _H) ← 3, (PC _L) ← 16x + y		X	Jumps to address xy of the current page.
	BL pxy	0 0 1 1 1 p p p p 1 1 x x x y y y y	0 7 p 1 8 y + x	2	2	(PC _H) ← p (PC _L) ← 16x + y		X	Jumps to address xy of page p.
	BA xX	0 0 0 0 0 0 0 0 1 1 1 x x x X X X X	0 0 1 1 8 x + x	2	2	(PC _L) ← 16x + (A) (PC _H) ← 3, (PC _L) ← 16x + (A)		X	Jumps to address x(A) of the current page. Jumps to the address x(A) of page 3 provided that none of instructions, RT, RTS, BL, BML, BLA or BMLA was executed after execution of instruction BM or BMA.

SINGLE-CHIP 4-BIT MICROCOMPUTER WITH TWO TIMER/EVENT COUNTER

Type of instruction	Mnemonic	Instruction code		No. of words	Functions	Skip conditions	Flag/CY	Description of operation
		D ₇ D ₆ D ₅ D ₄ C ₃ D ₂ C ₁ C ₀	16-bit notation					
Jumps	BLA pxy	0 0 0 0 0 0 0 0 1 0 0 1 1 1 P P P P 1 1 X X X X X X X X	0 0 1 0 7 P 1 X X + X	3	(PC _H) ← p (PC _L) ← 16x + (A)	—	X	Jumps to the address x(A) of page p.
	BM xy	1 0 x x x y y y y	1 x y	1	(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC) (PC _H) ← 2, (PC _L) ← 16x + y (PC _H) ← 2, (PC _L) ← 16x + y	—	X	Calls for the subroutine starting at address xX on page 2. Jumps to address xy of page 2 provided that none of instructions RT, RTS, BI, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
Subroutine calls	BML pxy	0 0 1 1 1 P P P P 1 0 x x x y y y y	0 7 P 1 x y	2	(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC) (PC _H) ← p, (PC _L) ← 16x + y	—	X	Calls for the subroutine starting at address xy of page p.
	BMA xX	0 0 0 0 0 0 0 0 1 1 0 x x x X X X X	0 0 1 1 X X	2	(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC) (PC _H) ← 2, (PC _L) ← 16x + (A) (PC _H) ← 2, (PC _L) ← 16x + (A)	—	X	Calls for the subroutine starting at address x(A) of page 2. Jumps to address x(A) of page 2 provided that none of instructions RT, RTS, BL, BML, BLA or BMLA was executed after the execution of instructions BM or BMA.
	BMLA pax	0 0 0 0 0 0 0 0 1 0 0 1 1 1 P P P P 1 0 x x x X X X X	0 0 1 0 7 P 1 X X	3	(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC) (PC _H) ← p, (PC _L) ← 16x + (A)	—	X	Calls for the subroutine starting at address x(A) of page p.
	RTI	0 0 1 0 0 0 1 1 0	0 4 6	1	(PC) ← (SK3) ← (SK1) ← (SK2) Resets interrupt flip-flop	—	X	Returns from interrupt routine to main routine. The internal flip-flop is restored to the value held immediately before the interrupt.
Program returns	RT	0 0 1 0 0 0 1 0 0	0 4 4	1	(PC) ← (SK0) ← (SK1) ← (SK2)	—	X	Returns to the main routine from the subroutine.
	RTS	0 0 1 0 0 0 1 0 1	0 4 5	1	(PC) ← (SK0) ← (SK1) ← (SK2)	Unconditional skip	X	Returns to the main routine from the subroutine, and unconditionally skips the next instruction.
	CLO CLS CLDS	0 0 0 0 1 0 0 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0 1 0 0 0 1	0 1 3 0 1 0 0 1 1	1 1 1	(D) ← 0 (SK) ← 0 (D) ← 0 (S) ← 0	—	X X X	Clears port D Clears port S Clears ports S and D.
Input/output	SD	0 0 0 0 1 0 1 0 1	0 1 5	1	(D(Y)) ← 1 where Y = 6 ~ 11	—	X	Sets the bit of port D that is designated by register Y.
	RD SZD	0 0 0 0 1 0 1 0 0 0 0 0 1 0 1 0 1 1	0 1 4 0 2 8	1 1	(D(Y)) ← 0 where Y = 0 ~ 11	—	X X	Resets the bit of port D that is designated by register Y. Skips the next instruction if the contents of the bit of port D that is designated by register Y and 0.
	OSAB	0 0 0 0 1 1 0 1 1	0 1 6	1	(S ₇ - S ₄) ← (B) (S ₇ - S ₄) ← (A)	—	X	Decodes contents of register A by PLA and the result is output to port S.
	OSPA	0 0 0 0 1 0 1 1 1	0 1 7	1	(S ₇ - S ₄) ← through PLA ← (A)	—	X	Decodes contents of register A by PLA and the result is output to port S.
	OSE	0 0 0 0 0 1 0 1 1	0 0 8	1	(S) ← (E)	—	X	Outputs contents of register E to port S.
	IAS i	0 0 1 0 1 0 1 0 1	0 5 4 + i	1	(A) ← (S ₇ - S ₄) i = 1: (A) ← (S ₇ - S ₃)	—	X	Transfers from port S to register A. The high-order four bits of port S are transferred when the value of i in the instruction is 0 or the low-order four bits are transferred when the value of i is 1.
	OFA	0 1 0 0 0 0 0 0 1	0 8 1	1	(F) ← (A)	—	X	Transfers the port F input to register A.
	IAF	0 1 0 0 0 1 1 0 0	0 8 0	1	(A) ← (F)	—	X	Transfers the port F input to register A.
	OGA	0 1 0 0 0 0 1 0 0	0 8 4	1	(G) ← (A)	—	X	Outputs contents of register A to port G.
	IAK	0 0 1 0 1 0 1 1 1	0 5 7	1	(A) ← (K)	—	X	Transfer the port K input to register A.
	SZK j	0 0 1 0 1 0 1 1 1	0 5 8 + j	1	(K(j)) ← 0	—	X	Skips the next instruction if the jth bit of port K input is 0.
	SU	0 0 0 0 0 0 1 1 1	0 0 7	1	(L) ← 1	—	X	Sets port U to 1.
	RU	0 0 0 0 0 0 1 1 0	0 0 8	1	(L) ← 0	—	X	Resets port U to 0.
Interrupts	EI	0 0 0 0 0 0 1 0 1	0 0 5	1	(INTE) ← 1	—	X	Sets interrupt flag INTE to enable interrupts.
	DI	0 0 0 0 0 0 1 0 0	0 0 4	1	(INTE) ← 0	—	X	Resets interrupt flag INTE to disable interrupts.
Misc.	NOP	0 0 0 0 0 0 0 0 0	0 0 0	1	(PC _H) ← (PC _L) ← 1	—	X	No operation.

Note 1. This list shows the machine codes and corresponding machine instructions. D₃~D₀ indicate the low order 4 bits of the machine code and D₈~D₄ indicate the high-order 5 bits. Hexadecimal numbers are also shown that represent the codes. An instruction may consist of one, two, or three words, but only the first word is listed. Code combination indicated with a bar (-) must not be used.

Note 3. Relationships for branching by means of branching instructions and subroutine calling instructions.

Note 2. Two-Word Instructions

	Second word
BL	1 1xxx yyy
BML	1 0xxx yyyy
BA	1 1xxx XXXX
BMA	1 0xxx XXXX

Three-Word Instructions

	Second word	Third word
BLA	0 0111 pppp	1 1xxx XXXX
BMLA	0 0111 pppp	1 0xxx XXXX

**SINGLE-CHIP 4-BIT MICROCOMPUTER

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{DD}	Supply voltage		0.3 ~ -20	V
V _I	Input voltage (ports D and S, and input V _P)		0.3 ~ 33	V
V _I	Input voltage, inputs other than ports D and S, and input V _P	With respect to V _{SS}	0.3 ~ -20	V
V _O	Output voltage, ports D and S		0.3 ~ -33	V
V _O	Output voltage, other outputs than ports D and S		0.3 ~ -20	V
P _d	Power dissipation		T _a = 25°C	1100
T _{opr}	Operating temperature		-10 ~ 70	°C
T _{stg}	Storage temperature		-40 ~ 125	°C

4

RECOMMENDED OPERATING CONDITIONS (T_a = -10 ~ 70°C, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V _{DD}	Supply voltage	-11	-12	-13	V
V _{SS}	Supply voltage		0		V
V _P	Pull-down transistor supply voltage	0		-33	V
V _{IH}	High-level input voltage, ports S and F	-1.5		0	V
V _{IH}	High-level input voltage, port D	-1.0		0	V
V _{IH} (φ)	High-level clock input voltage	-1.5		0	V
V _{IL}	Low-level input voltage, inputs other than ports D and S	V _{DD}		-4.2	V
V _{IL}	Low-level input voltage, ports D and S	-33		-4.2	V
V _{IL} (φ)	Low-level clock input voltage	V _{DD}		V _{DD} + 2	V
V _{OL}	Low-level output voltage, ports D and S	-33		0	V
f(φ)	Internal clock oscillation frequency	300		600	kHz

Note 1. V_{IL}(φ) is specified for the maximum V_{DD} value.

ELECTRICAL CHARACTERISTICS (T_a = -10 ~ 70°C, V_{DD} = -12V 10%, V_{SS} = 0V, f(φ) = 300 ~ 600kHz, unless otherwise noted)

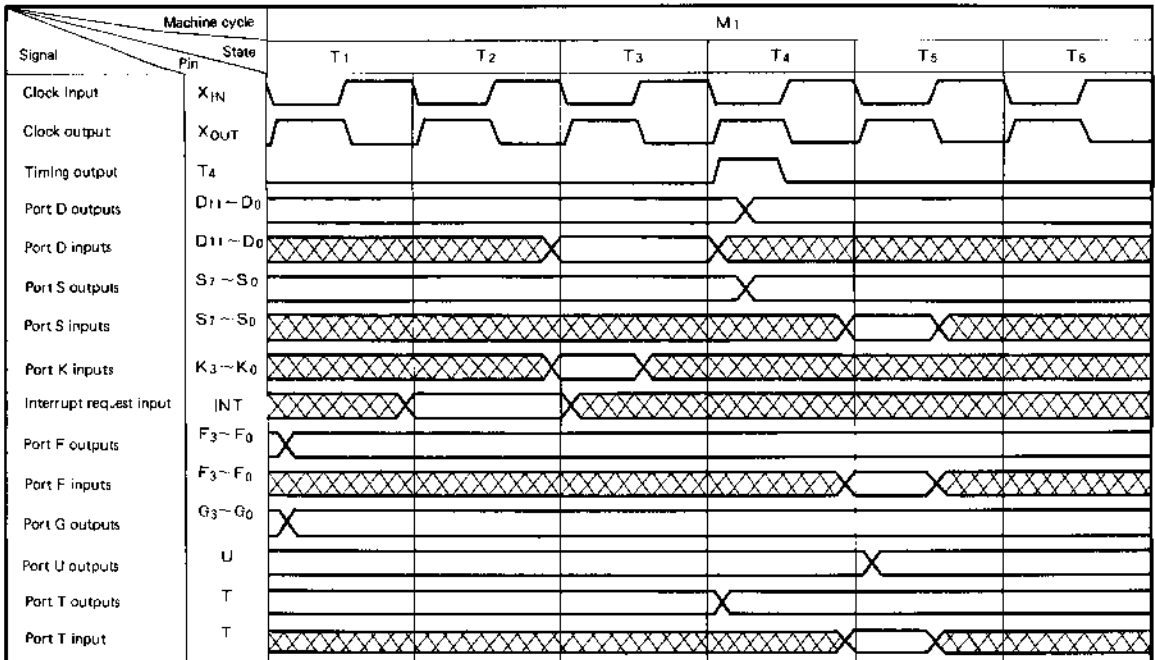

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
V _{IL}	Low-level output voltage, port F		V _{DD}		-4.2	V
V _{OH}	High-level output voltage, port D	V _{DD} = -12V, I _{OH} = -15mA, T _a = 25°C	-2.5			V
V _{OH}	High-level output voltage, ports S and F	V _{DD} = -12V, I _{OH} = -8mA (port S) I _{OH} = -5mA (port F), T _a = 25°C	-2.5			V
V _{T-}	Negative threshold voltage (Schmitt input mask option)	V _{DD} = -12V, T _a = 25°C	7		-4	V
V _{T+} - V _{T-}	Hysteresis (Schmitt input mask option)	V _{DD} = -12V, T _a = 25°C	2		3.5	V
I _I (φ)	Clock input current	V _I (φ) = -12V, T _a = 25°C		-20	-40	μA
I _{IH}	High-level input current, port K (with pull-down resistors)	V _{DD} = -12V, V _I = 0V, T _a = 25°C	50		250	μA
I _{IH}	High-level input current, ports D and S (with pull-down resistors)	V _P = -33V, V _I = 0V, T _a = 25°C	80		280	μA
I _{OH}	High-level output current, port D (Note 2)	V _{DD} = -12V, V _{OH} = -2.5V, T _a = 25°C			15	mA
I _{OH}	High-level output current, ports S and F	V _{DD} = -12V, V _{OH} = -2.5V, T _a = 25°C		-5 (port F) -8 (port S)		mA
I _{OL}	Low-level output current, ports D and S	V _{OL} = -33V, T _a = 25°C			-33	μA
I _{OL}	Low-level output current, port outputs	V _{DD} = -12V, T _a = 25°C			-33	μA
I _{DD}	Supply current	V _{DD} = -12V, T _a = 25°C		21		mA
C _i (φ)	Clock input capacitance	V _{DD} = X _{OUT} = V _{SS} , f = 1MHz, 25mVrms			10	pF

Note 2. Currents are taken as positive when flowing into the IC (zero signal condition), with the minimum and maximum values as absolute values.

3. It is possible to connect up to 5 lines of the port D at maximum ratings (-15mA) or all lines of port S and F at maximum ratings of (-8mA) and (-5mA) respectively.

MITSUBISHI MICROCOMPUTERS M58847-XXXSP

SINGLE-CHIP 4-BIT MICROCOMPUTER

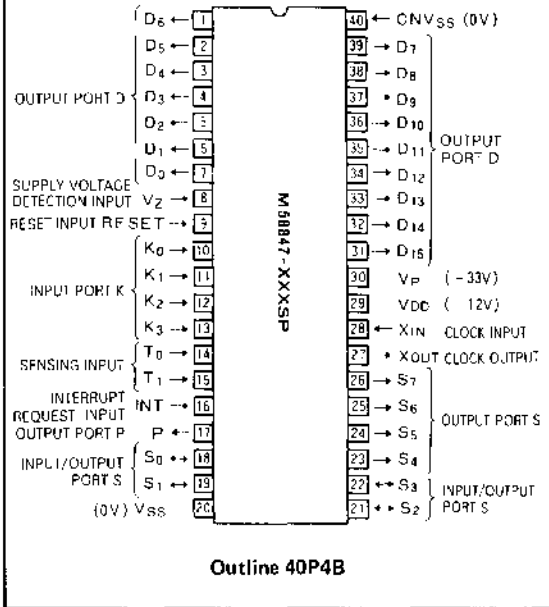

DESCRIPTION

The M58847-XXXSP is a single-chip 4-bit microcomputer fabricated using p-channel aluminum gate ED-MOS technology. It is housed in a 40-pin shrink plastic molded DIL package and provides 25 output lines, 4 input lines, 2 sensing lines and 1 interrupt input. Because of its low power consumption, it is ideal for consumer electronics applications requiring many control signals.

FEATURES

- Basic machine instructions 52
- Instruction execution time (for 1 word instructions using a 400kHz clock frequency) 15 μ s
- Memory capacity: ROM 2048 words x 9 bits
RAM 128 words x 4 bits
- Single -12V power supply
- Subroutine nesting 2 levels
- Interrupt function 1 factor, 1 level
- Input (port K) 4 ports
- Output (ports D and P) 17 ports
- Input/output (port S) 8 ports
- Sensing input (port T) 2 ports
- High withstanding voltage and large current output
- Built-in pull-down transistors (ports T, K, D, P, and S, mask option)
- Built-in clock generator circuit

PIN CONFIGURATION (TOP VIEW)

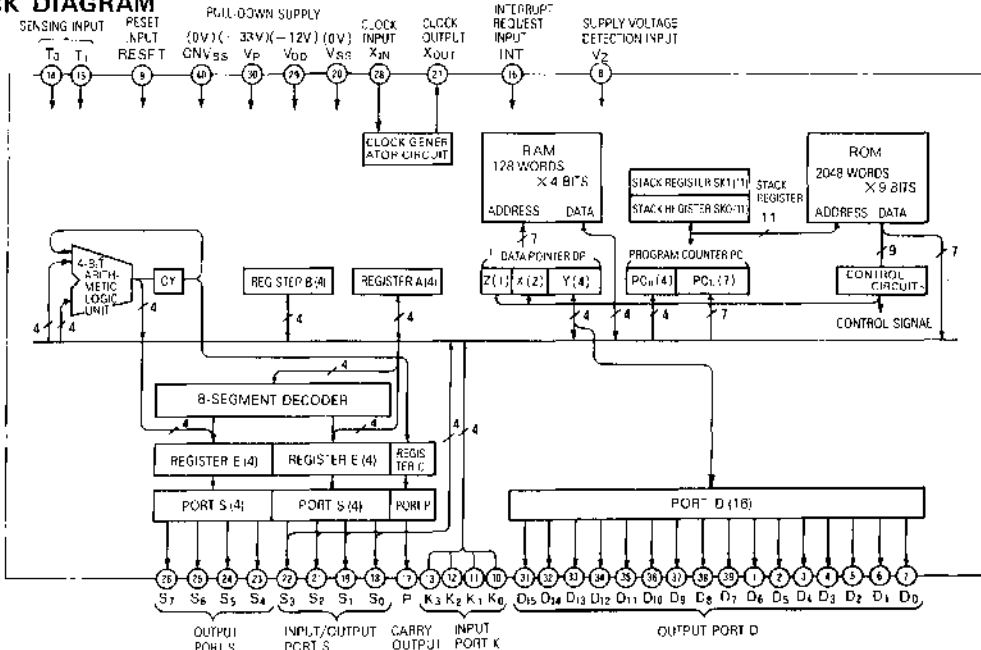

4

APPLICATIONS

- VTRs, TVs, cassette decks
- Microwave ovens, air conditioners, heaters, washing machines, home sewing machines
- Office equipment, copying machines, medical equipment
- Educational equipment, electronic games

Parameter		Performance	
Basic machine instructions		52	
Instruction execution time		15 μ s (1-word instructions using a clock frequency of 400 kHz)	
Clock frequency		240 kHz ~ 400 kHz	
Memory capacity	ROM	2048 words x 8 bits	
	RAM	128 words x 4 bits	
Input/output ports	K	Input	4 bits x 1
		Output	8 bits x 1
	S	Input	4 bits x 1
		Output	1 bit x 1
	D	Output	1 bit x 16
	T	Sensing input	1 bit x 2
Subroutine nesting		2 levels (including one level of interrupt)	
Clock generator		Built-in (externally connected RC circuit or ceramic resonator)	
I/O characteristics of ports	I/O withstanding voltage	- 33V	
	Ports P and S output current	- 8 mA	
	Port D output current	- 15mA	
Supply voltage	V _{DD}	- 12V	
	V _{SS}	0 V	
Device structure		p-channel aluminum gate ED-MOS	
Package		40-pin shrink plastic molded DIL package	
Power dissipation		10mW (typ)	

PIN DESCRIPTIONS

Pin	Name	Input or output	Function
V _{DD}	Supply voltage		V _{DD} and V _{SS} are the power supply pins. V _{DD} should be connected to -12V \pm 10% and V _{SS} should be grounded. V _P is the pull-down supply voltage input for the pull-down transistors (mask options) for ports P, S, and D.
V _{SS}	Supply voltage		
V _P	Pull down voltage input		
V _Z	Supply voltage detection input	In	This input pin is provided for use in detecting a drop in the supply voltage.
RESET	Reset input	In	This pin is used to initialize the microcomputer. If it is held high for at least two machine cycles after V _{DD} reaches to within 10% of -12V, the reset condition is enabled.
CNV _{SS}	CNV _{SS} input	In	This pin is not reserved for customer use but should be connected to V _{SS} .
X _{IN}	Clock input	In	These are the input and output pins for the built-in clock generator. A ceramic resonator element (240~400 kHz) or RC circuit may be connected to these pins to provide the required oscillation stability.
X _{OUT}	Clock output	Out	
T ₁ , T ₀	Sensing input	In	Sensing input pin
K ₃ ~ K ₀	Input port K	In	4-bit input port
S ₃ ~ S ₀	I/O port S	In/out	S ₃ ~ S ₄ and P comprise an output port S ₃ ~ S ₀ comprise an input/output port
S ₇ ~ S ₄	Output port S	Out	
P	Output port P	Out	
D ₁₅ ~ D ₀	Output port D	Out	The individual bits of this 16-bit output port may be set and reset separately.
INT	Interrupt request input	In	This interrupt signal input pin triggers on the input signal edge.

SINGLE-CHIP 4-BIT MICROCOMPUTER

BASIC FUNCTION BLOCKS

Program Memory (ROM)

This 2048 word x 9-bit ROM can be programmed with machine instruction codes in accordance with the customer's specifications. It consists of 16 pages, each containing an address range of 0~127.

The page is specified by the upper order 4 bits (PC_H) of the program counter.

The address within a particular page is specified by the lower order 7 bits which form a polynomial counter (PC_L). When the last address is reached (127), the address wraps around to the 0th address.

The BL instruction is used to branch to a different page than the current page. While the program counter is in reality a polynomial counter, a cross-assembly technique is used to allow the programmer to think of this counter as a normal pure binary counter, for ease in programming.

Page 0 and page 1 are special pages used for subroutine calls. The single-word instruction BM can be used to call a subroutine on page 0 from any arbitrary page. When the BM instruction is executed, the SM flag is set and until any of the BL, BML, RT or RTS instructions are executed, the B and BM instructions are used for functions differing from their normal functions.

Until any of the above listed instructions is executed after an BM instruction execution, the B instruction has the effect of branching to the 1st page and the BM instruction has the effect of branching to the 0th page. The flag SM is reset when the BL, BML, RT, or RTS instruction is executed.

Fig. 1 shows the ROM address map.

Program Counter (PC)

This counter is used to specify ROM addresses and the sequence of read-out of instructions stored in ROM. The upper 4 bits (PC_H) are used to specify the page in ROM and the lower 7 bits (PC_L) of which are a polynomial counter used to specify the address on the specified page.

Stack Registers (SK_0, SK_1)

These registers are used to temporarily store the contents of the PC while executing subroutines or interrupt programs until the program returns to the main routine.

The stack registers are organized in 2 words of 11 bits, allowing 2 levels of subroutine nesting.

Data Memory (RAM)

This 512-bit (128 words x 4 bits) RAM is used to store both processing and control data. One RAM word consists of 4 bits with bit manipulation possible over the entire storage area. The 128 words are arranged in 2 file groups x 4 files x 16 digits x 4 bits.

The word addresses for the data RAM are specified by means of the data pointer which consists of 1 bit of the register Z, 2 bits of the register X and 4 bits of the register Y. Fig. 2 shows the RAM address map. There are 8 files ($F_0 \sim F_7$) consisting of 16 words of 4 bits, which are convenient as a 16-digit register.

The specification for these file grimps is made by registers Z and X.

Data Pointer (DP)

This register is used to designate RAM addresses as well as bit position for the output port D. The data pointer is a 7-bit register, the uppermost bit of which is register Z which is used to specify the RAM file group, the central 2 bits of which form register X which is used to specify the RAM file, and the lower 4 bits of which form register Y which is used to specify the digit within the file. In addition, when the register Z's bit is 1, register Y is used to specify the bit position for the output port D.

4-bit Arithmetic Logic Unit (ALU)

This unit executes 4-bit arithmetic and logical operations by means of a 4-bit adder and related logic circuitry.

Register A and Carry Flag (CY)

Register A is a 4-bit accumulator that constitutes the basis for arithmetic operations. Data processing operations such as arithmetic and logical operations, data transfer, exchange, conversion, and data input/output are executed by means of this register. The carry flag CY is used to store carry or overflow after execution of arithmetic and logical operations by the arithmetic unit. The carry flag may also be used as a 1-bit flag.

4

Fig. 1 ROM address map

Fig. 2 RAM address map

SINGLE-CHIP 4-BIT MICROCOMPUTER

Registers B, E, and C

Register B is composed of 4 bits and can be used as a 4-bit temporary storage register or for 8-bit data transfer in conjunction with register A. Register E is an 8-bit register which can be used for temporary data storage or as an auxiliary register for input/output port S, and it also has left shift capability. Register C is a 1-bit register, to which the contents of the carry flag can be transferred. It can also be used to perform left shift when linked to register E.

Interrupt Functions

An interrupt input has been provided to allow the M58847-XXXSP to accept external interrupts. When the input signal changes from low to high, an edge-sensing flag is set, causing the interruption of the normally executed program if the interrupt enable flag is set. When an interrupt is received, the following things occur.

- (1) The program counter and SM flag are saved on each stack.
- (2) The program counter is set to the 0th address on page 2.
- (3) The SM flag and edge-sensing flag are reset.
- (4) The interrupt enable flag is reset.

In the above state the program begins at page 2, address 0, the first address of the interrupt program. The instruction RTI is used to end the interrupt program and return the processor to the main program flow.

Since the SM flag has a single-level stack, one level of

interrupt is possible. The program counter, however, has a two level stack, enabling subroutine nesting of one level after an interrupt uses one of these levels.

The microcomputer can accept an interrupt request in the following conditions.

When not executing a B, BL, BM, BML, LA, LXY, RT, RTS, RTI, DI, or EI instruction or not executing a skip operation and the interrupt enable flag is set.

Input/Output Ports

Ports T, K, S, D, and P may be provided with pull-down transistors as a mask option. Fig. 3 shows the circuits for the input/output ports.

In addition, the contents of the register A are decoded to 8 bits by built-in 8 segment decoder and transferred to register E or port S. The decoder function is fixed and not available in special forms as a mask option. Table 1 shows the decoder function.

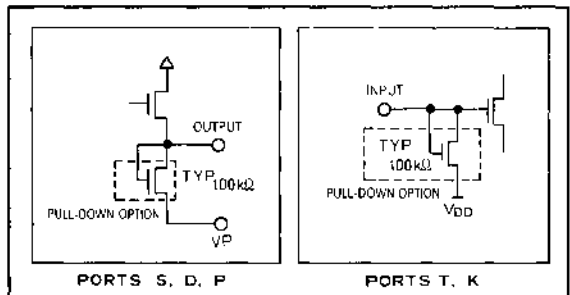

Fig. 3 Input/output circuits

Table 1 Decoder function table

Hexadecimal value	Register A				Port S output								Display
	A ₃	A ₂	A ₁	A ₀	S ₇	S ₆	S ₅	S ₄	S ₃	S ₂	S ₁	S ₀	
0	0	0	0	0	L	L	H	H	H	H	H	H	0

SINGLE-CHIP 4-BIT MICROCOMPUTER

Reset

The RESET input has been provided to enable initialization of the microcomputer. If the input is kept high for at least two machine cycles after the supply voltage V_{DD} reaches to within 10% of $-12V$, the microcomputer will be reset, enabling the following states.

- (1) The program counter is set to 0 ($PC \leftarrow 0$)
- (2) Ports S, P and D are turned off ($S \leftarrow 0$ ($P \leftarrow 0$ ($D \leftarrow 0$
- (3) Flag SM is reset ($SM \leftarrow 0$)
- (4) The edge-sensing flag is reset
- (5) The interrupt enable flag is reset ($INTE \leftarrow 0$)

Fig. 4 Power-on reset circuit

In addition, when the supply voltage V_{DD} is in the range $-7V \sim -13.2V$ and the V_Z input is driven high, an internal transistor is turned on and the RESET pin is set to the level of V_{SS} . Even if the V_Z pin returns to low, the internal transistor will remain turned on until the RESET pin is driven high. By using this function it is possible to sense temporary drops in the supply voltage to allow reset at these times to return to normal operation.

Clock Generator Circuits

A clock generator circuit has been built in to allow control of the frequency by means of an externally connected RC circuit or ceramic resonator. The choice of frequency determining element is made at the time of purchase as a mask option. Circuit examples are shown in Fig. 5~7.

Mask Options

- Port T pull-down transistors
- Port K pull-down transistors
- Port D pull-down transistors
- Port S pull-down transistors
- Port P pull-down transistors
- Oscillation conditions

MACHINE INSTRUCTIONS

Type of instruction	Mnemonic	Instruction code				16mal notation	No. of words	No. of cycles	Functions	Skip conditions	Flag/CY	Description of operation				
		D ₇	D ₆	D ₅	D ₄								D ₃	D ₂	D ₁	D ₀
Register-to-register transfers	TAB	0	1	0	1	1	0	0	0	1	1	(A) ← (B)	—	×	Transfers contents of register B to register A.	
	TBA	0	1	0	1	1	0	0	1	0	1	(B) ← (A)	—	×	Transfers contents of register A to register B.	
	TAY	0	1	0	1	1	0	1	0	0	1	(A) ← (Y)	—	×	Transfers contents of register Y to register A.	
	TYA	0	1	0	1	1	0	1	1	0	0	(Y) ← (A)	—	×	Transfers contents of register A to register Y.	
	TEAB	0	1	0	1	1	0	0	0	1	0	(E ₇ ← E ₆) ← (B), (E ₆ ← E ₅) ← (A), (C) ← (CY) (D ₃) ← (CY)	—	×	Transfers contents of registers A and B to register E, and the contents of the carry flag to register C.	
	TEPA	0	1	0	1	1	0	0	0	0	0	(E ₇ ← E ₆) ← 8-segment decoder ← (A), (C) ← (CY)	—	×	Decodes contents of register A in the B-segment decoder and transfers result to register C. The contents of the carry flag are transferred to register	
TXA	0	1	1	1	0	1	0	1	0	1	(X) ← (A ₁ A ₀) (Z) ← (A ₃) (CY) ← (A ₇)	—	0/1	Transfers the first and second bits of the register A to register X, complements of the third bit to register Z, and complement of the fourth bit to the carry flag CY.		
	TAX	0	1	1	1	1	0	0	1	0	(A ₁ A ₀) ← (X) (A ₂) ← (Z) (A ₃) ← (CY)	—	×	Transfers the contents of register X to the first and second bits of register A, complement of the contents of register Z to the third bit of register A, and complement of the contents of the carry flag CY to the fourth bit of register A.		
FAM address	LXy x,y	0	0	1	y	y	x	x	0	4	8	(X) ← x, where x = 0 - 3 (Y) ← y, where y = 0 - 15	Written successively	×	Loads value of "x" into register X, and of "y" into Y. When LXy is written successively, the first is executed and successive ones are skipped.	
	LZ z	0	0	0	0	0	1	1	0	0	0	(Z) ← z, where z = 0, 1	—	×	Loads value of "z" into register Z.	
	INY	0	1	1	1	0	0	1	0	0	0	(Y) ← (Y) + 1	(Y) = 0	×	Increments contents of register Y by 1. Skips next instruction when new contents of register Y are "0".	
	DEY	0	1	1	1	0	1	0	0	0	1	(Y) ← (Y) - 1	(Y) = 15	×	Decrements contents of register Y by 1. Skips next instruction when new contents of register Y are "15".	
	SADR j	0	1	1	0	0	0	j	j	0	C	j = 0 : specifies the 0th digit of F4 j = 1 : specifies the 0th digit of FE j = 2 : specifies the 0th digit of F6 j = 3 : specifies the 0th digit of F7	—	×	During the following instruction cycle only, the 0th digit of the file specified by the immediate field (in the range F4 to F7). The contents of the data pointer remain unchanged.	
RAM accumulator transfers	TAM j	0	1	0	1	0	0	j	j	0	A	(A) ← (M(DP)), (X) ← (X) ∨ where, i = 0 - 3	—	×	Transfers the RAM contents addressed by the active DP to register A. Register X is then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X.	
	XAM j	0	1	0	1	1	j	j	0	A	C	(A) ← (M(DP)), (X) ← (X) ∨ where, i = 0 - 3	—	×	Exchanges the contents of the RAM (and register A. Contents of X are then "exclusive OR-ed" with the value j and the result stored in register X.	
	XAMD j	0	1	0	1	0	1	j	j	0	A	3	(A) ← (M(DP)), (X) ← (X) ∨ (Y) ← (Y) - 1 where, i = 0 - 3	(Y) = 15	×	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction, and the result stored in register X. The contents of register Y are incremented by 1, and when the result is 15, the next instruction is skipped.
	XAMJ j	0	1	0	1	0	1	j	j	0	A	4	(A) ← (M(DP)), (X) ← (X) ∨ (Y) ← (Y) + 1 where, i = 0 - 3	(Y) = 0	×	Exchanges the contents of the RAM and register A. Contents of X are then "exclusive OR-ed" with the value j in the instruction and the result stored in register X. The contents of register Y are incremented by 1, and when the result meets with the marked skip condition, or, the next instruction is skipped.
Arithmetic operation	LA n	0	1	0	0	n	n	n	0	8	n	(A) ← n, where n = 0 - 15	Written successively	×	Loads the value n into register A. When LA is written consecutively the first is executed, and successive ones are skipped.	
	AM	0	1	0	1	1	1	1	0	0	E	(A) ← (A) + (M(DP))	—	×	Adds the contents of the RAM to register A. The result is retained in register A, and the contents of flag CY are unaffected.	
	AMC	0	1	0	1	1	1	0	0	0	C	(A) ← (A) + (M(DP)) + (CY), (CY) ← Carry	—	0/1	Adds the RAM contents addressed by the active DP and contents of flag CY to register A. The result is stored in register A, and the carry in the active flag CY.	
	AMCS	0	1	0	1	1	1	0	1	0	0	(A) ← (A) + (M(DP)) + (CY), (CY) ← Carry	Carry = 1 A carry is not produced and = 0 ≠ 6	0/1	×	Adds the contents of the RAM and flag CY to register A. The result is stored in register A and the carry in the CY, but the next instruction is skipped when a carry is produced.
	A n	0	1	0	0	1	n	n	n	0	9	n	(A) ← (A) + n, where n = 0 - 15	—	×	Adds value n in the instruction to register A. The contents of flag CY are unaffected and the next instruction is skipped if a carry is not produced, except when n=6.
	SC	0	0	0	0	0	1	1	0	0	0	6	(CY) ← 1	—	1	Sets active flag CY.
	RC	0	0	0	0	0	1	0	1	0	0	5	(CY) ← 0	—	0	Resets active flag CY.
SZC	0	0	0	0	0	1	0	0	0	0	2	(CY) ← 0 ?	(CY) = 0	×	Skips next instruction when contents of the active flag CY are 0.	
CMA	0	1	0	1	1	1	1	1	0	0	7	(A) ← (A)	—	×	Stores complement of register A in register A.	
Bit operation	SB j	0	0	0	0	1	0	0	j	0	1	(M _j (DP)) ← 1, where, j = 0 - 3	—	×	Sets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	RB j	0	0	0	0	1	0	1	j	0	1	(M _j (DP)) ← 0, where, j = 0 - 3	—	×	Resets the jth bit of the RAM addressed by the active DP (the bit designated by the value j in the instruction).	
	SZB j	0	0	0	0	1	0	1	j	0	1	(M _j (DP)) ← 0 ?	(M _j (DP)) = 0	×	Skips next instruction when the contents of the jth bit of the RAM addressed by the active DP (the bit which is designated by the value j in the instruction) are 0.	
Comparisons	SEAM	0	1	0	1	1	1	1	1	0	F	(V(DP)) = (A) ?	(M(DP)) = A	×	Skips next instruction when contents of register A are equal to the RAM contents addressed by the active DP.	
	SEY y	0	0	0	1	0	y	y	y	0	2	(Y) ← y?, where, y = 0 - 15	(Y) = y	×	Skips next instruction when the contents of register Y are equal to the value y in the instruction.	
Jumps	B xy	1	1	x	x	y	y	y	1	8	y	(PCL) ← 16x + y, where, (SM) = 0 (PCH) ← 1	—	×	Jumps to address xy of the current page.	
	BL pxy	0	0	0	1	p	p	p	0	3	p	(PCL) ← 0, (SM) ← 0 (PCL) ← 16x + y	—	×	Jumps to address xy on page 1 when executed, provided that none of instructions RT, RTS, BL or BML was executed after execution of instruction BM.	

MITSUBISHI MICROCOMPUTERS M58847-XXXP

SINGLE-CHIP 4-BIT MICROCOMPUTER

Type of instruction	Mnemonic	Instruction code			No. of words	No. of cycles	Functions	Skip conditions	Flag CY	Description of operation
		D ₇	D ₆ D ₅ D ₄ D ₃	D ₂ D ₁ D ₀						
Subroutine calls	BM xy	1	0 xxx yyyy	1xy	1	2	(SK) ₀ ← (SK ₀) ← (PC), where, (SM) = 0 (PC) ₀ ← 0, (PC) ₁ ← 16x + y, (SM) ← 1 (PC) ₀ ← 0 (PC) ₁ ← 16x + y, where, (SM) = 1			Calls for the sub-routine starting at address xy on page 0. Jumps to address xy of page 0 provided that none of instructions RT, RTS, BL or BML was executed after the execution of instruction. BV
	BML pxy	0	0 0 1 1 pppp	0 3 p 1 0 xxx yyyy	1	3	(SK) ₀ ← (SK ₀) ← (PC) (PC) ₀ ← p, (PC) ₁ ← 16x + y, (SM) ← 0			Calls for the subroutine starting at address xy of page p.
Program returns	RT	0	0 0 0 1 1 1 1 1	0 1 F	1	2	(PC) ₀ ← (SK ₀) ← (SK ₀), (SM) ← 0			Returns to the main routine from the subroutine.
	RTS	0	0 0 0 1 1 1 1 0	0 1 E	1	2	(PC) ₀ ← (SK ₀) ← (SK ₀), (SM) ← 0	Unconditional skip		Returns to the main routine from the subroutine, and unconditionally skips the next instruction.
Interrupts	EI	0	0 0 0 0 1 0 1 1	0 0 B	1	1	(INTE) ← 1			Sets interrupt flag INTE to enable interrupts.
	DI	0	0 0 0 0 1 0 1 0	0 0 A	1	1	(INTE) ← 0			Resets interrupt flag INTE to disable interrupts.
	RTI	0	0 0 0 1 1 1 0 1	0 1 D	1	2	(PC) ₀ ← (SK ₀) ← (SK ₀), (SM) ← (SM ₀)			Returns from interrupt routine to main routine. The internal subroutine mode flag is restored to the value held immediately before the interrupt.
Input/output	SD	0	0 0 0 0 1 1 1 1	0 0 F	1	1	(D(Y)) ← 1, where, (Z) = 1			Sets the bit of port D, that is designated by register Y, when the contents of register Z are 1.
	RD	0	0 0 0 0 1 1 1 0	0 0 E	1	1	(D(Y)) ← 0, where, (Z) = 1			Resets the bit of port D, that is designated by register Y, when the contents of register Z are 1.
	OSAB	0	1 0 1 1 0 0 1 1	0 B 3	1	1	(S ₀ ← S ₀) ← (E ₀ ← E ₀) ← (R), (P) ← (C) ← (CY), (S ₁ ← S ₁) ← (E ₁ ← E ₁) ← (A)			Outputs contents of registers A and B to port S, and the contents of the carry flag to port P.
	OSPA	0	1 0 1 1 0 0 1 0	0 B 2	1	1	(S ₀ ← S ₀) ← (E ₀ ← E ₀) ← 8 segment decoder (A), (P) ← (D) ← (CY)			Decodes contents of register A by 8 segment decoder and the result is output to port S, and output the contents of the carry flag to port P.
	OSE	0	1 1 1 1 0 0 1 0	0 F 2	1	1	(S ₀ ← S ₀) ← (E ₀ ← E ₀), (P) ← (C)			Outputs contents of registers E and C to ports S and P.
	SHFT	0	0 0 0 0 1 0 0 0	0 0 B	1	1	(E ₀) ← (E ₀ ← 1), (E ₁) ← (C) ← (CY)			Inputs register E and register C and shifts left. The contents of register C are shifted into the least significant bit of register E and the contents of the flag CY are shifted into register C. The most significant bit of register E is lost.
	IAS	0	1 1 1 1 1 0 0 0	0 F 8	1	1	(A) ← (S ₀ ← S ₀)			Transfers the 4 lower order bits of port S to register A.
	IAK	0	1 0 1 1 1 0 0 0	0 B 8	1	1	(A) ← (K ₀ ← K ₀)			Transfers the 4 bits of port K to register A.
Misc	SZTO	0	0 0 0 0 0 0 0 1	0 0 1	1	1	T ₀ = 0 ?	T ₀ = 0		Skips the next instruction if the sensing input T ₀ is low.
	SZTI	0	0 0 0 0 0 1 0 0	0 0 4	1	1	T ₁ = 0 ?	T ₁ = 0		Skips the next instruction if the sensing input T ₁ is low.
	CLDS	0	0 0 0 0 0 1 1 1	0 0 7	1	1	(D) ← 0, (S) ← 0, (P) ← 0			Clears ports D, S and P.
NOP	0	0 0 0 0 0 0 0 0	0 0 0	1	1	(PC) ← (PC) + 1				No operation.

MITSUBISHI LSIs M58494-XXXP

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M58494-XXXP is a single-chip 4-bit microcomputer fabricated using CMOS technology in a 72-pin plastic flat package. It has a 4096-word by 10-bit mask-programmable ROM and a 32-word by 4-bit RAM. RAM capacity can be expanded to as much as 4096 words by 4 bits by directly connecting generally available CMOS RAMs.

The device is designed for application where the low power dissipation of CMOS is essential.

FEATURES

- Basic machine instructions 92
- Basic instruction execution time
(at 455kHz clock frequency) 8.8μs
- Large memory capacity:
 - ROM 4096-word x 10-bit
 - Internal RAM 32-word x 4-bit
 - External RAM 4906-word x 4-bit (max)
- Single 5V power supply
- Saving of last data pointer 4-level
- Subroutine nesting 12-level
- Internal timer:
 - Timer 1 14-bit
 - Timer 2 4-bit
- Internal event-counter 4-bit
- I/O port for external RAMs (all three-state)
 - Address (port A) 12-bit
 - Control signals (R/W, OD) 2-bit
 - Data I/O (port D) 4-bit
- General-purpose registers 32-bit
- I/O port (port Q) 8-bit
- I/O port (port R) 4-bit x 2
- I/O port (serial data port) 2-bit

PIN CONFIGURATION (TOP VIEW)

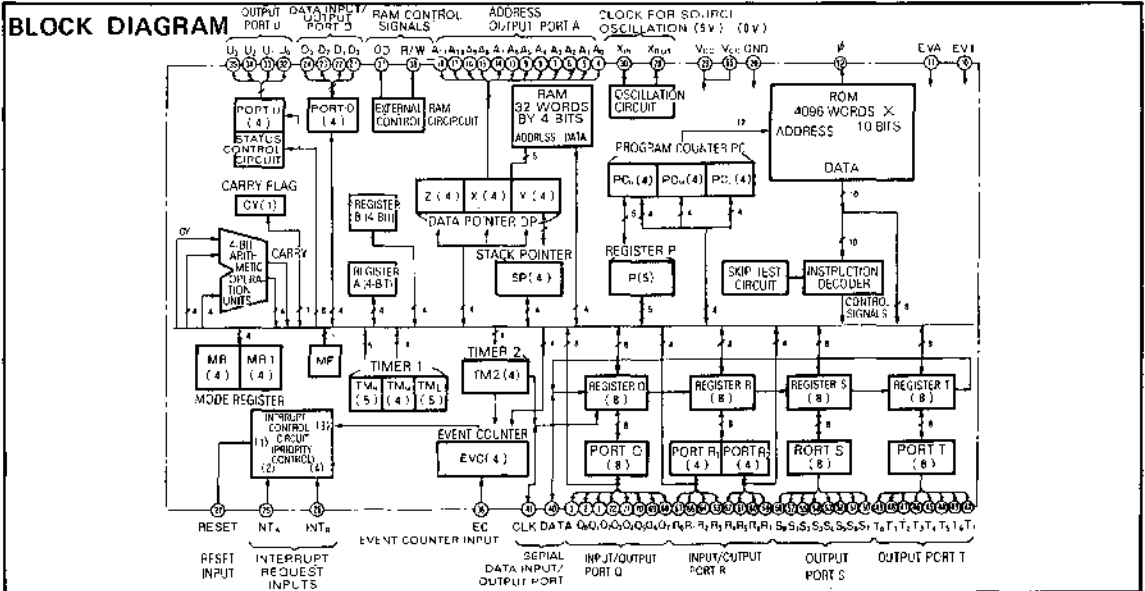

Package Outline 72P2

- Output ports (port S, port T) 8-bit x 2
- Output port (port U, three-state output) 4-bit
- Event-counter input (port EC) 1-bit
- Interrupt function
(priority interrupt type) 4-factor, 1-level

APPLICATIONS

- Electronic cash registers, electronic calculators (with printer and/or programmable)
- Office machines, intelligent terminals, data terminals
- Sewing machines, knitting machines, etc.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Outline Specifications of M58494-XXXP

Item		Performance	
Number of basic instructions		92	
Execution time of basic instructions		8.8 μ s (at $V_{CC} = 5V, f = 455kHz$)	
Clock frequency		100 ~ 455 kHz	
Memory capacity	ROM	4096 words \times 10 bits	
	RAM (built-in)	32 words \times 4 bits	
	RAM (external)	4096 words \times 4 bits (max.)	
Input/output port for external RAM	Address (port A)	12 bits \times 1 (3 states)	
	Control signal (port OD and R/W)	2 bits (3 states)	
	Data bus (port D)	4 bits \times 1 (3 states)	
Input/output port	Q	Input	8 bits \times 1
		Output	8 bits \times 1
	R	Input	4 bits \times 2
		Output	8 bits \times 1
	S	Output	8 bits \times 1
	T	Output	8 bits \times 1
	DATA	Serial data	1 bit (input/output port)
	CLK	Synchronizing pulse	1 bit (input/output port)
U	Output	4 bits \times 1 (3-state)	
EC	Input	1 bit	
Subroutine nesting		12 levels	
Interrupt request		4 factors 1 level	
Saving of data pointer		4 levels	
Clock generation circuit		Built-in (oscillation reference element is outside)	
Ports input/output characteristics	Absolute maximum rating voltage	V_{CC}	
	Input/output characteristics	Interchangeable with CMOS logic series	
Power supply voltage	V_{CC}	5V (nominal)	
	V_{SS}	0 V	
Element structure		CMOS	
Package		72-pin plastic molded flat package	
Power dissipation		5 mW (at $V_{CC} = 5V, f = 455kHz$)	

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

PIN DESCRIPTIONS

Pin	Name	Input or output	At reset	Function
X _{IN}	Source oscillation clock input	Input	—	Incorporates the clock oscillation circuit, for setting of the oscillation frequency. The oscillation reference device such as a ceramic filter for 1F is connected between X _{IN} and X _{OUT} . When an external clock is used, connect the clock oscillation source to the X _{IN} pin and leave the X _{OUT} pin open.
X _{OUT}	Source oscillation clock output	Output	—	
RESET	Reset signal	Input		Resets the program counter PC and mode registers, and performs the reset initiation of the related input ports and output ports. For input/output ports, refer to the column for "At reset" of this table.
INT _A	Interrupt request signal A	Input	Disable	Input signals for interrupt request. Request is accepted on the rising edge of the signal. Besides these external input signals, the interrupt requests, T from timer 2/event counter are also received in the relative order RESET > INT _A > INT _T > INT _B . Since the interrupt requests are held at each latch, there will be none undetected.
INT _B	Interrupt request signal B	Input	Disable	
EC	Event counter input	Input	—	The input signal for the event counter, which program 2 ⁰ ~ 2 ⁿ events of the event mode. This value is set as an initial value and countdown starts from this value to reach F ₃₄ , which then generates interrupt request signal INT _T .
A ₀ ~A ₁₁	Address output port A	Output	Floating	The address signal for main memory (RAM) externally connected, in the form of a 3-state output. At MM mode where external memory is used the data of the data pointer DP is read out directly. In SM mode where internal memory (RAM) is used, the data of the data pointer Y immediately before switching to MM mode is transferred to the auxiliary latch (4 bits) prior to read-out. However, the lower 8 bits of the address signal (A ₈ ~A ₇) are not affected by this mode, since data pointers X and Z are not related to latch operation.
D ₀ ~D ₃	Data input/output port D	Input/output	Floating	A 3-state input/output port to execute data transfer in 4 bit units to/from an externally connected main memory (RAM). Switching of input/output is made automatically by instruction.
OD	External RAM read signal	Output	Floating	The output port is 3-state and the read signal generated at the data input cycle is in the externally connected main memory (RAM). During a read cycle, it becomes automatically set to low-level.
R/W	External RAM write signal	Output	Floating	The output port is 3-state and the write signal generated at the data write cycle is in the externally connected main memory (RAM). During a write cycle, it is automatically set to low-level.
U ₀ ~U ₃	Output port U	Output	Floating	The output port enables 3-state setting per 1-bit unit. The 3-state condition is modified by the data content of register B, and the data of register A is output. The output setting of port U, however, is made either by instruction SU unconditionally or by the instruction TPRA or TPRN, which transfers the data of the general-purpose register to ports Q, R, S and T.
Q ₀ ~Q ₇	Input/output port Q	Input/output	Input	The input/output port for 8-bit data transfer to/from register Q. Register Q enables data transfer between register A and register B. By instruction OPI, this port also functions to load the value (8-bit) of the immediate field of the ROM to register Q. Port Q data can be transferred to registers A and B as an input signal of 8 bits.
R ₀ ~R ₇	Input/output port R	Input/output	Input	The input/output port for 8-bit data transfer to/from register R. Register R enables data transfer between register A and register B. By instruction OPI, this port also functions to load the value (8-bit) of the data field of the ROM to register R. When port R is used as the input signal of a 4-bit unit, the data, 4 bits each can be transferred to register B.
S ₀ ~S ₇	Output port S	Output	Low-level	The output port that enables 8-bit data transfer to/from register S. Register S enables data transfer between register A and register B. By instruction OPI, this port also functions to load the value (8 bit) of the data field of the ROM to register S.
T ₀ ~T ₇	Output port T	Output	Low-level	The output port for 8-bit data transfer to register S. Register T enables data transfer between register A and register B. By instruction OPI, this also functions to load the value (8-bit) of the immediate field of the ROM to register T.
DATA	Serial data port	Input/output	Floating	The input/output port normally is floating to handle the serial data of the 32-bit general-purpose register. At output mode data of the least significant bit of the general-purpose register (the least significant bit of register T) is read out, and at the input mode, the input is to the most significant bit of the general-purpose register (the most significant bit of register D).
CLK	Serial data shift clock signal	Input/output	Floating	The input/output port is normally floating to generate a shift clock pulse synchronized with the above serial data port. At output mode a shift clock pulse synchronized with the data transmission is generated and at the input mode, a shift pulse synchronized with the rate of data receiving is applied.

5

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

BASIC FUNCTIONAL BLOCKS AND THEIR OPERATIONS

Program Memory ROM

The ROM stores 32-pages by 128 words of program and its addressing is performed by a program counter. The program counter consists of a 7-bit binary sequential counter and a 5-bit page register.

Program Counter PC

The ROM is composed of 32 pages of 128 words, and when program execution completes instruction at address 127, the binary counter is set to 0 and the next page is automatically incremented in the page-designation register.

The 12-bit contents of the program counter PC can be saved for up to 12 levels in the fixed stack area of the external main memory (RAM). In the execution of instructions BM and BMA, control can be returned to a former routine by storing the contents of the program counter before branching, in the execution of instructions RT, RTS, and RTI.

Register P

In the page register, the contents of register P are loaded by instructions 8L, BA, BM and BMA. Instruction BMAB branches unconditionally to the address derived by using the contents of register A for the low-order 4-bits of the 12-bit PC, those of register B for the middle 4-bits, and those of the upper 4-bits of the 5-bit register P for the upper 4-bits, and then executes the instruction OPI of the branch, and simultaneously returns automatically.

Stack Pointer SP

A stack of 12 levels is provided for saving of the program counter PC in the fixed address area within the external main memory (RAM), and the contents of the stack pointer are used during addressing. The contents of the stack pointer are incremented by an interruption or in the execution of instructions BM and BMA, and are decremented in the execution of instructions RT, RTS and RTI.

Data Memory RAM

The internal RAM is used to store data in the form of two files each consisting of 16 words by 4 bits. The external RAM can be expanded up to 4096 words by 4 bits. These addresses are designated by a 12-bit data pointer. The contents of the data pointer can be saved for up to 4 levels in the stack region (fixed region in the external RAMs) by execution of a special instruction. The external RAM can be easily expanded without any extra interface circuits by connecting a 12-bit address signal, the 2-bit RAM control signal and the 4-bit data input/output signal. These signals can address external RAMs for up to 4096 x 4-bit words,

thus incrementing the basic external minimum RAM organization of 256 x 4-bit words.

Data Pointer DP

This is a register of 12 bits addressing memory, being composed of registers X, Y, and Z, having 4 bits each. Register X address 16 files, each of which comprises 16 words. Register Y address data of 16 files (a file comprises 16 words). Register Z permits address specification such that data memory may be extended up to maximum of 16 sets of 4096 words by 4 bits, where one unit comprises 16 files (256 words by 4 bits).

Since the address of the external main memory (4096 words by 4 bits maximum) and the internal scratch-pad memory (32 words by 4 bits) are designated identically, the external main memory is selected by instruction MM, and the internal scratch-pad memory by instruction SM.

The contents of DP can be saved for up to 4 levels in the fixed stack region of the external main memory. This pointer is saved during the execution of instruction SDP, and is restored by instruction LDP.

When the data pointer stack is not used, the entire stack may be used as a program counter stack.

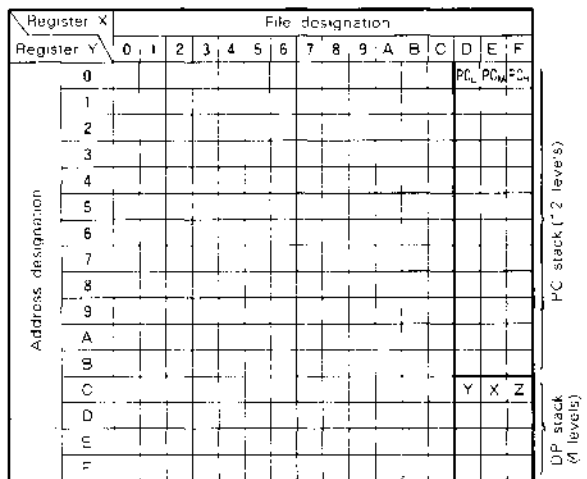

Fig. 1 External basic main memory (Z = 0) and RAM map

Table 1 Address designation of data pointer stack

Value of data field during execution of instructions SDP and LDP		Stack DP (file designated by register Y)
1 ₁	1 ₀	
0	0	C
0	1	D
1	0	E
1	1	F

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Accumulator (Register A), Carry Flag CY

Register A is an accumulator forming the central unit of a 4-bit-wide microcomputer. Data processing operations such as arithmetic, data transfer, data exchange, data conversion, input/output, etc. are executed principally with this register.

The carry flag CY stores the carry or borrow from the most significant bit of the arithmetic unit in the execution of specific arithmetic instructions, and is available for multipurpose uses as a one-bit flag.

Auxiliary Register (Register B)

Register B is composed of four bits. It is employed for bit operating functions, temporary memory of four-bit data and transfer of eight-bit data when coupled with register A, etc.

Four-Bit Arithmetic Logic Unit (ALU)

This unit carries out four-bit arithmetic and logical functions, and is composed of a four-bit adder and a logic circuit associated with it. It carries out addition, complement conversion, logic arithmetic comparison, arithmetic comparison, bit processing, etc.

General-Purpose Registers Q, R, S, and T

These general-purpose registers comprise a set of four 8-bit shift registers. When using combinations of functions such as serial input, serial output, parallel input and parallel output, by properly selected instructions, they are employed for data transfer between register A and register B, data transfer between output ports or input/output ports, data storage of the data field of the ROM value (8 bits), transmission of internal serial data, receiving of external serial data, etc.

Table 2 Relationship between input/output address N and general-purpose registers

Input/output address	Immediate data N in execution of the instructions BMAB, TNAB, TRPN, and TRPN		General-purpose register to be selected
N	1	0	
0	0	0	Register Q
1	0	1	Register R
2	1	0	Register S
3	1	1	Register T

Table 3 Mode setting by instruction SMR 1; when the general-purpose registers are employed as a 32-bit shift register

Mode flag	SDM	0	0	1	1
	RVM	0	1	0	1
DATA pin		Input	Output	Output	Output
CLK pin		Floating	Input (rising edge trigger)	Output (generated by timer 2)	Output (generated by shift instruction)
Shift data input	SST, HST	Immediate field data	0 input independent of executable instruction	Immediate field data	Immediate field data
	IST	DATA pin output		DATA pin output	DATA pin output
Shift clock pulse		Instructions SST, RST, IST	CLK input	Instructions SST, RST, IST	Instructions SST, RST, IST
Transmission/receiving		Receiving (only in instruction STI)	Transmission	Transmission	Transmission

Instruction OPI loads one of the four general-purpose registers selected by the input/output address N with the value (8 bits) of the data field. The input/output address N is latched with the contents of the lower 2 bits of the data field in the execution of the instructions BMAB, TNAB, TABN, TPRN and TRPN and determines the register which loads data in the execution of the instruction OPI.

When the general-purpose registers are used as a single 32-bit shift register, four kinds of modes as shown in Table 3 can be set by instruction SMR1.

Mode Register

The mode register is composed of 8 bits, and can select operation modes and functions, etc. of the associated input port or output port by setting or resetting the mode flag corresponding to a bit in register A.

The mode setting by the instruction SMR is shown in Table 4.

The mode setting by instruction SMR1 is shown in Table 5.

Interrupt Function

This microcomputer has a hardware interrupt function for four conditions by one-level. The interrupt requests comprise: the RESET signal; the interrupt request signals INT_A and INT_B as external signals; and the interrupt request signal INT_T by the internal event counter.

The fixed addresses to be jumped to and the priority order of four factors in the interrupt request are defined as follows:

- (1) In case of by reset signal RESET page 0, address 0
- (2) In case of interrupt signal INT_A page 0, address 2
- (3) In case of interrupt signal INT_T page 0, address 8
- (4) In case of interrupt signal INT_B page 0, address 4

A RESET signal restores the hardware to the initial state, independent of any current instruction.

In an interrupt enable state, the interrupt is accepted at the rising edge of interrupt request signals INT_A and INT_B. When an interruption is requested in an interrupt disable state, the interrupt is not executed. If the interrupt disable state is removed thereafter and a corresponding interrupt enable instruction is executed, the interrupt routine will be

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

executed immediately because the interrupt request has been held in the latch. The current interrupt request, held in a latch during the interrupt disable state, is reset by the interrupt disable instruction.

When two and more interrupt requests of four factors occur simultaneously, the interrupt processing is by order

of the highest priority routine. The interrupt request of lower priority order is held in the corresponding latch in an interrupt disable state. When the interrupt disable state is removed by the interrupt enable instruction (after completion of the interrupt process of upper priority order), the interrupt request of next lower priority is initiated.

Table 4 SMR mode setting

Bits of register A	Mode flag (contents of register A are stored)	Status	Function	Mode flag at reset
A ₀	IMQ	0	Port Q is used as an 8-bit input port	0
		1	Port Q is used as an 8-bit output port	
A ₁	LCD	0	For output port U, only instruction cat set port U	0
		1	For output port U, instructions TPRN and TPRA for port Q, R, S and T can also set port U.	
A ₂	IMR1	0	Port R ₁ is used as a 4-bit input port	0
		1	Port R ₁ is used as a 4-bit output port	
A ₃	IMR2	0	Port R ₂ is used as a 4-bit input port	0
		1	Port R ₂ is used as a 4-bit output port	

Table 5 SMR 1 mode setting

Bits of register A	Mode flag (contents of register A are stored)	Status	Function	Mode flag at reset
A ₀	TMM	0	Event mode, event counter is used with EC input.	0
		1	Timer mode, event counter is used in combination with timer 2.	
A ₁	BF	0	All signals (A ₁₁ ~A ₀ , D ₃ ~D ₀ , OD and R/W) for external main memory (RAM) are put in floating.	0
		1	All signals (A ₁₁ ~A ₀ , D ₃ ~D ₀ , OD and R/W) for external main memory (RAM) are activated.	
A ₂	RVM	0	When the general-purpose registers are used as a 32-bit shift register, functions of transmission/receiving, terminals DATA and CLK are employed properly by RVM, SDM flags. For further details, refer to explanation of the general-purpose register.	0

Timers and Event Counter

This block is composed of a 14-bit timer 1, a 4-bit timer 2 and a 4-bit event counter.

Timer 1 is a standard timer that continuously counts the frequency X_{IN}, divided by fourteen. The timer performs accurate counting and the period is given by the following formula:

$$(\text{Fundamental output frequency } X_{IN}) \times 2^5 (TM_L) \times 2^4 (TM_M) \times 2^5 (TM_H) = \text{cycle time of timer 1}$$

By the continuous use of instructions TATM and TBTM, the contents of TM_M are stored in register B, the contents of the lower 4 bits of TM_H in register A, and the high-order bit of TM_H in carry flag CY, respectively. The contents of timer 1 can be accessed. Instruction

Fig. 2 Outline of timer 1 configuration

RTM clears the contents of timer 1 and resets it to 0.

Timer 2 is composed of a 4-bit counter and a 4-bit latch. The contents of register A are stored as the starting value in the latch and the counter by an STM instruction, whereupon counting down starts in synchronization with each machine cycle. When the contents of the counter become F during countdown, the pre-programmed starting value is restored in the counter from the latch.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

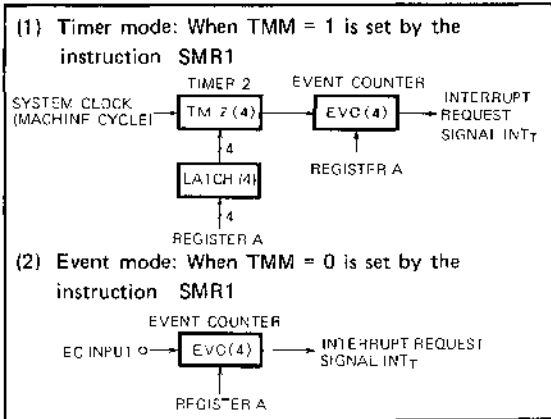

Fig. 3 Outline configuration of timer 2 and event counter

The cycle period of timer 2 is given by the following formula:

$$\text{Machine cycle} \times [1 + (2^0 \sim 2^4)]$$

When the timer mode is set by SMR1 instruction, timer 2 is connected to the event counter. Every time the contents of timer 2 become F the event counter counts down once. For the event counter, the contents of register A can be stored in the counter and used as a starting value by using instruction SEC.

When the event mode is set using instruction SMR1, the event counter is counted down by sensing the rising edge of external event counter input EC.

In both timer mode and event mode, the event counter is counted down from a starting value, and an interrupt request signal is generated when the contents become F.

The time necessary for INT_T generation from the starting value is given by the following formulas:

Timer mode

$$\text{Machine cycle} \times [1 + (2^0 \sim 2^4)] \times (2^0 \sim 2^4)$$

Event mode

$$\text{EC input period} \times (2^0 \sim 2^4)$$

Reset Function

Applying a low-level input to the RESET input pin for 3 machine cycles or more causes the reset state. Power-on reset is provided by such circuit as shown in Fig. 4.

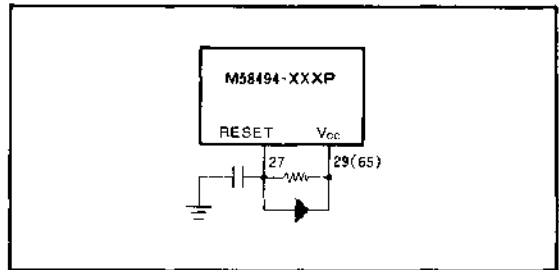

Fig. 4 Power-on reset circuit

5

Clock Generation Circuit

Clock pulses are easily generated by connecting an external IF ceramic filter between the pins X_{IN} and X_{OUT}. An example of such a circuit is shown in Fig. 5. If the clock signal is to be supplied from an external source, the clock source should be connected to pin X_{IN}, leaving the X_{OUT} pin open. An example of such circuit is shown in Fig. 6.

Fig. 5 External oscillation element connections

Fig. 6 External clock input circuit (Note 1)

Note 1 Low and high input levels should be set such that
input level = 0~0.8V
Output level = V_{CC} - (V_{CC} - 0.8)V
and such that the duty cycle is 40 to 60% with respect to the X_{IN} input.

MITSUBISHI MICROCOMPUTERS M58496-XXXP

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

DESCRIPTION

The M58496-XXXP is a single-chip 4-bit microcomputer fabricated using CMOS technology. Its features are liquid crystal display direct drive circuit, current saving circuit for back-up of a 22-stage frequency divider and RAM.

This device is designed for applications in which clock and liquid crystal display functions are included and where the low-power dissipation achieved by CMOS is especially important.

FEATURES

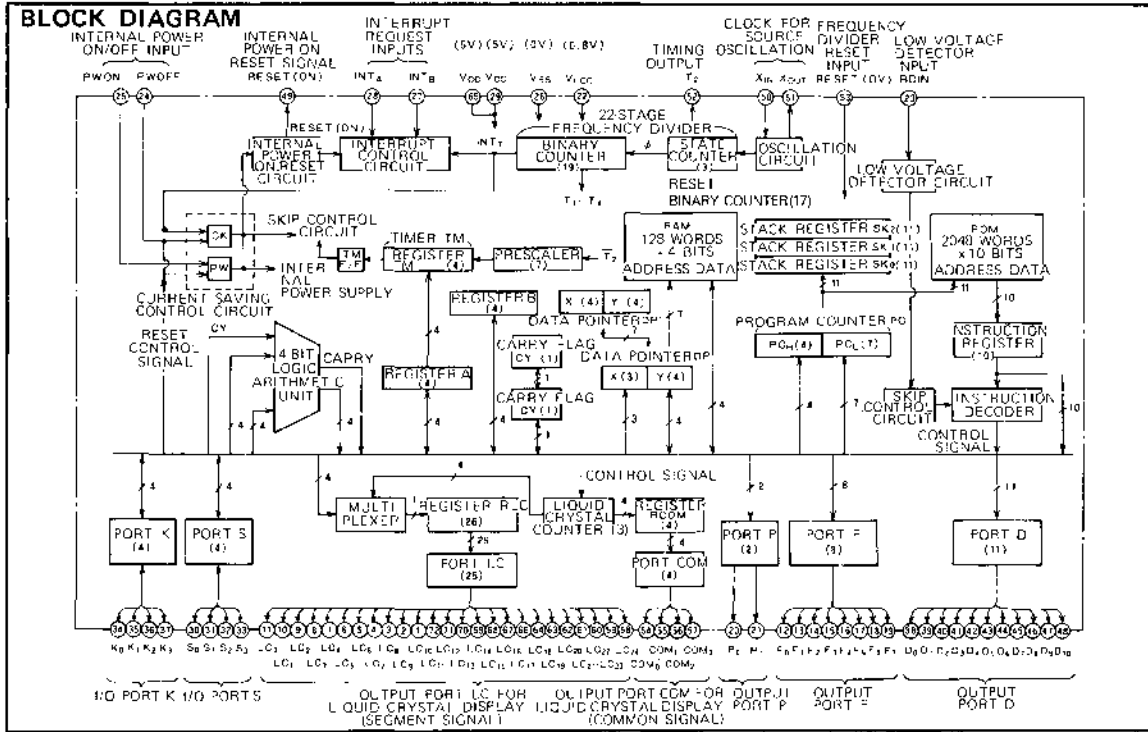

- Single 5V power supply
- Basic machine instructions 77
- Basic instruction execution time (at 4.2MHz liquid crystal frequency) 7.7 μ s
- Memory capacity: ROM 2048 words x 10 bits
Internal RAM . . . 128 words x 4 bits
External RAM . . . 256 words x 4 bits
- Internal crystal oscillation circuit
- Internal 22-stage frequency divider
- Low voltage detector circuit
- Internal current saving circuit while idling
- Subroutine nesting 3 levels
Internal timer: Prescaler . . . 7 bits Timer . . . 4 bits
- Output ports for liquid crystal display
segment signal (port LC) 25 bits
common signal (port COM) 4 bits
- I/O Ports (ports K and S) 4 bits x 2
- Output port (port D) 1 bit x 11

- Output port (port F) 1 bit x 8
- Output port (port P) 1 bit x 2
- Interrupt function 4 factors, 1 level

APPLICATIONS

- Electronic cash registers and calculators with printer
- Office machines, intelligent terminals and data terminals
- Electronic Games
- Electronic coin and changer machines
- Sewing machines

MITSUBISHI MICROCOMPUTERS

M58496-XXP

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

FUNCTION

The M58496-XXP consists of mask ROM and RAM, a 4-bit arithmetic logic unit, crystal oscillation circuit, 22-stage frequency divider, power saving circuit, low voltage detector circuit, 4-bit timer, interrupt circuit and a liquid crystal display direct drive circuit. The RAM capacity can easily be expanded by the external connection of 256-word by 4-bit CMOS RAM.

The ROM storage is organized as 16 pages of 128 words which is used mainly for programs. Addressing the ROM is done through the program counter. The address register is structured as a 7-bit address register and a 4-bit page register. The address register is counted up as nonbranching instructions are executed. When a nonbranching instruction at address 127 on a page is executed an overflow of the address register is produced. This carry (overflow) is disregarded so the page register is not counted up and the next instruction to be executed will come from address 0 on the same page.

When an interrupt request is accepted control is transferred to fixed addresses as follows: in case of an internal power on reset signal (RESET(ON)) the program is set to page 0 address 0, for the INT_A signal it is set to page 0 address 2, for the INT_B signal it is set to page 0 address 4 and for the output signal INT_T(second signal) of the 22-stage frequency divider it is set to page 0 address 8.

The internal RAM which is configured as 8 files of 16 words is used for data storage and each word can be addressed. The internal RAM is addressed by a 7-bit data pointer. The internal RAM can be augmented by external RAM consisting of up to 16 files of 16 words. The external

RAM is addressed by the 8-bit combined register Y (4 bits) and register B (4 bits).

RAM addressing, register-to-register transfers, RAM-to-accumulator transfers, arithmetic operations, input/output operations and timer operation are performed mainly through register A (accumulator).

The current saving circuit used in conjunction with the 22-stage frequency divider and RAM can be controlled by the PWOFF input and instruction.

The low voltage detector circuit is also active while the power source is a battery. Low voltage is sensed by the program and an indication can be output.

The output ports for direct drive of the liquid crystal display are port LC (25 terminals) and port COM (4 terminals). The liquid crystal display can be driven by 1/4 duty, 1/3 bias or 1/3 duty, 1/3 bias.

Output port D consists of 11 individually latched bits that can be used to output not only 1-bit data but can also output data such as the contents of register Y of the data pointer and 8-bit addresses for external RAM.

Output port F consists of 8 individually latched bits that can be used to output data. It can be set or reset by instructions.

Output port P consists of 2 terminals through which a synchronous signal of 1 machine cycle width can be output by instruction.

The combined 7-bit output of ports F and P can be used to directly fetch the contents of ROM addressed by the data field of an instruction.

The I/O ports K and S consist of 4 terminals through which data can be transferred to and from register A.

PERFORMANCE SPECIFICATIONS

Item		Performance	
Number of basic instructions		77	
Execution time of basic instructions		7.7 μ s (V _{CC} =5V, f=4.1943MHz)	
Clock frequency		250 ~ 525kHz	
Memory Capacity	ROM	2048 words x 10 bits	
	Internal RAM	128 words x 4 bits	
	External RAM	256 words x 4 bits	
I/O Port	LC	Liquid crystal display output	
	COM	4 bits	
	K	Input	4 bits
		Output	4 bits (Note 1)
	S	Input	4 bits
		Output	4 bits (Note 1)
	D	Output	11 x 1 bit (open drain)
	F	Output	8 x 1 bit (Note 1)
P	Output	2 x 1 bit (Note 1)	
Frequency divider		22-stage built in	
Current saving circuit		Built in	
Low voltage detector		Built in	
Subroutine nesting		3 levels (including 1 level of interrupt)	
Interrupt request		4 factors, 1 level	
Clock generation circuit		Built in (4.1943 MHz crystal oscillator external) (Note 2)	
Input/output port	Output voltage	6V (max)	
	Output current	-0.4 mA (min.)	
Power supply voltage	V _{CC}	5V (nom)	
	V _{SS}	0V	
Liquid crystal display driving supply voltage		0.8V (nom)	
Element structure		CMOS	
Package		72-pin plastic molded flat package	
Power dissipation (open output terminals)	In operation	5mW (V _{CC} =5V, 525 kHz)	
	In idle	1.5mW (V _{CC} =5V, 525 kHz)	

Note 1: Ports K, S, F, and P are connected to high impedance pull down resistors when high driving current is required, external resistors are required.

2: External oscillator can be selected by mask option.
 (1) 4.1943 MHz crystal oscillator
 (2) 465 kHz ceramic oscillator

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

PIN DESCRIPTION

Pin	Name	Input or output	At reset (internal power-on)	Function
X _{IN}	Source oscillation clock input	Input	—	Incorporates the clock oscillation circuit, for setting the frequency. An oscillation reference device such as a crystal oscillator is connected between X _{IN} and X _{OUT} . When an external clock is used, connect the clock oscillation source to the X _{IN} pin and leave the X _{OUT} pin open.
X _{OUT}	Source oscillation clock output	Output	—	
PWON	Internal power on input	Input	—	Incorporates the power saving circuit. Its control inputs are PWON and PWOFF. The 22-stage frequency divider and RAM are put in the idle state by a PWOFF input.
PWOFF	Internal power off input	Input	Low level	
RESET (OV)	Frequency divider reset input	Input	—	Incorporates the 22-stage frequency divider as the crystal oscillation reference device. This is a reset input for up to lower 17 steps of the divider.
BDIN	Low voltage detector input	Input	—	The low voltage detector circuit is built in. A resistor should be connected to the BDIN pin for voltage sensing.
INT _A	Interrupt request A signal	Input	Interrupt disable	This input signal is for an interrupt request. The request is accepted on the rising edge of the signal. Besides these external input signals, an interrupt request INT _T from the 22 stage frequency divider output signal is sensed as an interrupt.
INT _B	Interrupt request B signal	Input	Interrupt disable	
LC ₀ ~ LC ₂₄	Liquid crystal display segment output	Output	—	Incorporates the liquid crystal display direct drive circuit. It is suitable for liquid crystal display at 1/4 duty and 1/3 bias. The output ports for direct drive of the liquid crystal display are port LC (LC ₀ ~ LC ₂₄) and port COM (COM ₀ ~ COM ₃).
COM ₀ ~ COM ₃	Liquid crystal display common output	Output	—	
V _{LCD}	Power supply for liquid crystal display	—	—	This is the power supply terminal for a liquid crystal display. It includes the bias resistor for the segment and common signals.
D ₀ ~ D ₁₀	Output port D	Output	Floating	This output port consists of 11 bits. Each output is individually latched and can be selected to be set or reset by the contents of register Y. Also 8 bits of the port can be used to fetch 8-bit addresses for external RAM.
F ₀ ~ F ₇	Output port F	Output	Low level	The output port consists of 8 bits. Each output is individually latched and can be set or reset by instructions.
P ₀ , P ₁	Output port P	Output	Low level	This output port consists of 2 bits from which 1 synchronous signal of 1 machine cycle width can be output per instruction. The immediate 7-bit field of an instruction can be output through this port in combination with 5 bits of port F.
K ₀ ~ K ₃	Input/output port K	Input/output	Low level	Ports K and S are 4-bit latched input/output ports through which data can be transferred to and from register A. When output is low-level the output will be high-impedance so it can be used as an input port.
S ₀ ~ S ₃	Input/output S	Input/output	Low level	
T ₂	Timing output	Output	—	The timing output is used for testing the device.
HESET(OV)	Internal power-on reset signal	Output	Low level	When the internal power supply is switched on, a built-in automatic reset circuit generates a high level reset signal that resets the I/O ports.

5

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

DESCRIPTION OF OPERATION

Program Counter PC

The program counter is an 11-bit address register. The high-order 4 bits designate the page number and as a group are called PC_H. The low-order 7 bits designate the address on the page and as a group are called PC_L. The PC designates the address of the 2048 words by 10-bit mask-programmable ROM. The ROM is organized into 16 pages of 128 words. As instructions are fetched from ROM, PC_L is incremented so that unless there is a branch executed instructions are fetched and executed in sequence. Care must be taken when the last instruction on a page (address 127) is executed because when PC_L is incremented it becomes zero with a carry, but the carry is disregarded so the next instruction to be fetched will be the start of the same page. Therefore to move to the next page PC_H must be modified by using branch instructions such as BL, BML, BLA and BMLA.

Pages 14 and 15 are special pages designed to accommodate subroutines. Subroutines starting on page 14 can be called by 1-word instructions BM or BMA. These instructions automatically load PC_H to designate page 14 and in addition the return address and control status are saved so they can be restored when the subroutine transfers control back to the main program. If the instructions BM or BMA are executed on page 14, they execute a branch within page 14 without saving any information. If the instructions B or BA are executed on page 14, they execute a branch to page 15.

Stack Registers SK₀, SK₁, SK₂

The 3-level stack register consists of 11-bit registers for storing the contents of the program counter when control is transferred from the main program to a subroutine or interrupt. When control is transferred back to the main program, the PC can be restored. There are 3 levels, but when 1 level is saved for interrupts it leaves 2 levels for subroutine nesting.

Data Pointers DP, DP'

The data pointer is a 7-bit register used to designate the address of RAM or the bit position of output port D. The data pointer is composed of the 3-bit register X and the 4-bit register Y. Internal RAM is organized as 8 files of 16 words. Register X designates the file and register Y designates the word position of a file or the bit position of output port D.

The data pointer DP' is selected by software during interrupt processing to leave the contents of DP unchanged (saves the DP).

External RAM is organized as 16 files of 16 words that can be added to the system to expand memory. Register Y designates the word position of a file while register B designates the file.

Register A (accumulator) and Carry Flags CY, CY'

Register A is the 4-bit accumulator forming the heart of the 4-bit microcomputer. Data processing operations such as arithmetic, transfer, exchange, conversion, and input/output are executed principally through this register.

The carry flags CY are to store the carry or borrow from the most significant bit of the arithmetic unit resulting from executing the various instructions. It can be tested and used for various purposes. In principle it acts as a 1-bit flag.

The carry flag CY' is selected by software to leave the contents of CY unchanged (saves the CY).

Register B (Auxiliary Register)

Register B is a 4-bit register used for temporary storage of 4-bit data. It also is used to designate the file number of external RAM.

Arithmetic Logic Unit (ALU)

The arithmetic logic unit performs 4-bit arithmetic and logical operations. The heart of the ALU is a 4-bit adder and the logic circuit associated with it. It performs operations such as additions, complement conversions, logic arithmetic comparisons and bit processing.

Frequency Divider and Timer

The frequency divider divides the basic oscillation frequency into 22 stages. It is connected to the basic oscillation device through X_{IN} and X_{OUT}. The frequency divider generates the interrupt request signal INT_T to the interrupt control circuit. The frequency divider sets flag CK for controlling the power saving circuit.

Basic oscillation for the timer is the timing signal T₂. The timer is composed of a 7-bit prescaler and a 4-bit counter. Timer flag TMF/F is set when a timer overflows, and is sensed by the TTM instruction. The 4-bit timer counter is set by the STM instruction. Prescaler and timer flag are reset at the same time.

Power Saving Circuit

The power saving circuit is controlled by the CK flag and PW. Its output is input to the internal power supply reset circuit and generates an interrupt request signal RESET (ON). Control is transferred unconditionally to address 0 on page 0 and resets the I/O ports. The interrupt request

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

signal RESET (ON) generates on the rising edge of internal power supply on reset output. Internal power supply is switched off by the external terminal and stop instruction, but power is maintained to the following circuits:

1. Internal data memory (RAM)
2. Clock oscillation circuit
3. 22-stage frequency divider
4. Low voltage detector circuit
5. Power saving circuit

Low Voltage Detector Circuit

The low voltage detector circuit connects the resistor for sensing voltage to the BDIN terminal. A falling voltage level is sensed by the program and can be displayed by using apt output port.

Interrupt Functions

The M58496-XXXP has internal circuits to process interrupt requests from 4 single level sources. The 4 interrupt request sources are external interrupt signals INT_A and INT_B , internal power supply reset output RESET (ON), output INT_T from the 22-stage frequency divider. Interrupt requests INT_A , INT_B and INT_T are enabled by the instructions EIA, EIB and EIT respectively and disabled by the instruction DIA, DIB and DIT respectively. Interrupt requests from the internal power supply through reset output RESET (ON) cannot be disabled and will cause an interrupt whenever received.

During the interrupt enable state an interrupt request by INT_A or INT_B is accepted on the rising edge of the signal. When an interrupt request is received during the interrupt disable state it is latched, but is not executed. When the disable is removed thereafter by executing the corresponding interrupt enable instruction, the interrupt request will be accepted immediately and control transferred to the interrupt routine because the request was latched. A current interrupt request, held by latching during interrupt disable state is reset when the corresponding interrupt disable instruction is executed.

One level of the 3-level stack register is required when interrupt programs are used. This leaves 2 levels available for subroutine processing. After an interrupt is processed control is returned to the main program by executing a return instruction such as RTI. Care must be taken after starting an interrupt program to save the contents the data pointer DP, register A, carry flag and any other registers used, so the contents can be restored before returning to the main program. The contents must be saved and restored by the interrupt program.

When an interrupt request is accepted the program counter, interrupt enable flag and skip flag are affected as follows:

(1) Program counter

The contents (the current program address) are stored in the stack register. Control is transferred to address 0 on page 0 by a RESET (ON) interrupt, to address 2 on page 0 by an INT_A interrupt, to address 4 on page 0 by an INT_B interrupt or to address 8 on page 0 by an INT_T interrupt by setting the control counter to 00, 02, 04 or 08 respectively. When control is transferred to address 0 page 0, the instruction is invalid and is not executed, so the first instruction is executed from address 1 on page 0.

(2) Interrupt enable flags

When an interrupt request is accepted additional interrupts are disabled until the accepted interrupt is processed. Except that a RESET (ON) interrupt may be accepted at any time.

(3) Skip flags

The skip flags are used to indicate an instruction skip and the NOP state for instructions LX Y and LA are saved. A special stack is provided for saving these flags.

5

General-Purpose I/O ports K, S, F, P and D

These 4-bit or 1-bit general-purpose registers are used for such things as data transfer between register A, instruction transfers, 1-bit transfers as selected by register Y, storing 7-bit immediate field data of instructions fetched from ROM, and data transfers between external RAM. Each output has a latch and its output circuit contains an open drain resistor or a pulldown resistor (high-impedance).

I/O ports K, S

Ports K and S are 4-bit latched I/O ports, that can transfer data to and from register A. Output latches are reset by the DIKS instruction when the port is being used as an input port.

Output port F

Port F is an 8-bit latched output port, that has independent latches for each bit. The individual bits can be set by the SF instruction and reset by the RF instruction.

Output port P

Port P is a 2-bit latched output port, that is usually in low-level, but can output the machine cycle high-level synchronous signal by SP_0 or SP_1 instructions. The 7 bits ($F_4 \sim F_0$, P_1 , P_0) can be used for direct fetching of the immediate field of the OTRO instruction.

Output port D

Port D is an 11-bit latched output port, that has independent latches for each bit. The contents for register Y indicate the individual bit to be set by the SD instruction or to be reset by the RD instruction. The 8-bit address of external memory (RAM) is output through this port.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Liquid Crystal Display Drive Circuit

The liquid crystal display direct drive circuit is composed of the following units. A block diagram of the units is shown in Fig. 1.

1 Control counter for the liquid crystal display

This is an octal counter composed of 3 bits and is counted down by the ELC instruction. The contents of the counter select 1 bit of register A and transfer data in order to the segment register RLC by the TLC instruction and determines the frame frequency for the liquid crystal display by transferring the contents of the counter to common register RCOM.

2 Register A

This 4-bit register is the accumulator. Its function is to control data processing, arithmetic operations control functions and input/output of the microcomputer.

3 Segment register RLC

The 26-bit segment register stores selected 1-bit data from register A by execution of the TLC instruction.

It shifts 1 bit in order and stores the segment signals for the liquid crystal display device.

4 Common register RCOM

The 4-bit common register stores the common signal for the liquid crystal display. The input for the common register is the converted contents of the control counter for the liquid crystal display.

5 Port LC

The 26-bit latched port LC stores data in parallel by the ELC or DLC instruction from the segment register RLC. A bias resistor provides for the output at 2 levels and the 25 low-order bits are output as standard type. The high-order bit is not output to an external terminal.

6 Port COM

Port COM has 4 bits of latched storage. The data is transferred in parallel by the ELC or DLC instruction through the common register (RCOM). The outputs of this port have 3 biased levels by means of bias resistors.

Fig. 1 Liquid crystal display drive circuit block diagram

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

RESET FUNCTION

As shown in Fig. 2, when the PWOFF input of the M58496-XXXP is driven low for at least 10ms, the input/output ports are reset and the interrupt disabled state is entered. (Refer to the descriptions of the power-on reset states in the Pin Description.) Next, if the PWON input is driven high, or an interrupt is generated by the internal power-on reset RESET (ON) caused by a frequency divider output INT_T, the program counter is set to address 0 page 0 as a starting location.

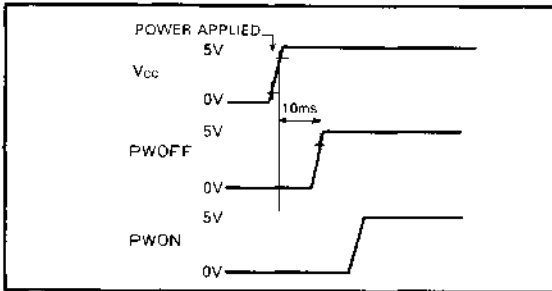

Fig. 2 Power-on reset circuit

CLOCK GENERATOR CIRCUIT

A built-in clock generator circuit has been provided and a quartz crystal or ceramic element (mask option) can be externally connected. In addition, an external clock source may be connected to pin X_{IN}, leaving pin X_{OUT} open. Circuit examples are shown in Fig. 3 and Fig. 4.

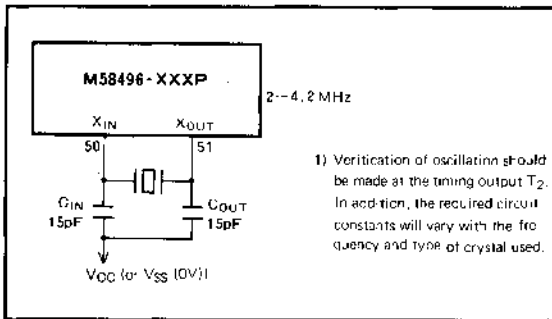

Fig. 3 External circuit connected by crystal oscillator

Fig. 4 External clock input circuit

Documentation Required Upon Ordering

The following information should be provided when ordering a custom mask.

- (1) M58496-XXXP mask confirmation sheet
- (2) ROM data 3 EPROM sets
- (3) Oscillation frequency selection
 On confirmation sheets
- (4) Frequency divider output selection (1Hz/2Hz)
 On confirmation sheets

Note 1: This list shows the machine codes and corresponding machine instructions. D₃~D₀ indicate the low-order 4 bits of the machine code and D₇~D₄ indicate the high-order 4 bits. Hexadecimal numbers are also shown that represent the codes. An instruction may consist of one or two words, but only the first word is listed. Code combination indicated with asterisk (*) and bar (—) must not be used.

Two-word instructions

	Second word
BL	11 0xxx yyyy
BLA	11 1xxx XXXX
BML	10 0xxx yyyy
BMLA	10 1xxx XXXX

Note 1: When the M58496-XXXP generates a skip it is not necessary to increment the program counter so no additional cycles are required for execution.

2: Instructions B, BA, BM or BMA execute the second function of the functions column when executed, provided that none of instructions BT, RTS, BL, BML, BLA or BMLA was executed after execution of instruction BM or BMA.

5

Symbol	Meaning	Symbol	Meaning
A	4-bit register (accumulator)	P (COMn)	Common output port for liquid crystal display
Ai	Indicates the bits of register A. Where i=1~3	P (LCn)	Segment output port for liquid crystal display
B	4-bit auxiliary register	PW F/F	1-bit power supply control flag display
BDOUT	Battery detector signal	R (COMn)	Common register for liquid crystal display (4 bits)
CK F/F	1-bit 1-second flag	R (LCn)	Segment register for liquid crystal display (25 bits)
CY	i-bit carry flag	S	4-bit I/O port
CY'	1-bit carry flag	SCA	Output of bit A of control counter for liquid crystal display
D	11-bit output port	SCB	Output of bit B of control counter for liquid crystal display
Di	Indicates the bits of port D. Where i=0~3	SK0	11-bit stack register
D(Y)	The bit of port D addressed by Y	SK1	11-bit stack register
DP	7-bit data pointer composed of register Y, X	SK2	11-bit stack register
Y, Y'	4-bit register	TM	4-bit timer/counter
X, X'	3-bit register	TM F/F	1-bit timer/counter flag
DP'	7-bit data pointer	xx	2-bit binary variable
DET F/F	1-bit battery detector flag	yyyy	4-bit binary variable
F	8-bit output port	mmm	3-bit binary variable
F _i	Indicates the bits of port F. Where i=0~7	nnnn	4-bit binary variable
K	4-bit I/O port	ii	2-bit binary variable
M(DP)	4-bit data of memory addressed by data pointer DP	jjj	3-bit binary variable
M _i (DP)	A bit of data of memory addressed by data pointer DP where i=0~3	XXXX	4-bit unknown binary variable (the value does not affect execution)
PC	11-bit program counter composed of PC _L , PC _H	←	Indicates direction of data flow
PC _L	Low-order 7 bits of the program counter	()	Indicates contents of register memory, etc.
PC _H	High-order 4 bits of the program counter	∨	Exclusive OR
P ₀	1-bit output port	∧	AND
P ₁	1-bit output port	—	Negation
		X	Indicates flag is unaffected by instruction execution
		xy	Label used to indicate the address xxx yyy
		C	Hexadecimal number C + binary number-X
		+X	
		X	

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage	With respect to V _{SS}	-0.3~6.0	V
V _I	Input voltage		-0.3~V _{CC} +0.3	V
V _O	Output voltage		0 ~ V _{CC}	V
P _d	Power dissipation	T _a =25°C	300	mW
T _{opr}	Operating free-air temperature range		0 ~ 50	°C
T _{stg}	Storage temperature range		-40 ~ 125	°C

RECOMMENDED OPERATING CONDITIONS (T_a=0~50°C, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Norm	Max	
V _{CC}	Supply voltage	4.5	5	5.5	V
V _{SS}	Supply voltage		0		V
V _{LCD}	Liquid crystal supply voltage		0.8		V
V _{IH}	High-level input voltage	V _{CC} -0.8		V _{CC}	V
V _{IL}	Low-level input voltage	0		0.8	V
f _{XIN}	Oscillator frequency	2		4.2	MHz
f _φ	Internal clock oscillator frequency	250		525	kHz

ELECTRICAL CHARACTERISTICS (T_a=0~50°C, V_{CC}=5V±10%, V_{SS}=0V, f_{XIN}=2~4.2MHz, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
I _{OH}	High-level output current, port D	V _{OH} =(V _{CC} -0.5)V	-0.4	-0.8		mA
I _{OH}	High-level output current, ports F, P, K, and S	V _{OH} =(V _{CC} -0.5)V	-0.4	-0.6		mA
I _{OL}	Low-level output current, ports F, P, K, and S	V _{OL} =0.5V		2	20	μA
V _{OH}	High-level output voltage, port LC	V _{CC} =5V, V _{LCD} =0.8V, T _a =25°C	3.75	3.95		V
V _{OH}	High-level output voltage, port COM	V _{CC} =5V, V _{LCD} =0.8V, T _a =25°C	4.8	5		V
V _{OX}	Medium-level output voltage, port COM (Note 1)	V _{CC} =5V, V _{LCD} =0.8V, T _a =25°C	2.7	2.9	3.1	V
V _{OL}	Low-level output voltage, port LC	V _{CC} =5V, V _{LCD} =0.8V, T _a =25°C		1.85	2.05	V
V _{OL}	Low-level output voltage, port COM	V _{CC} =5V, V _{LCD} =0.8V, T _a =25°C		0.8	1	V
I _{CC}	Supply current, full operating condition	V _{CC} =5V, T _a =25°C, Output pins open		0.7	1	mA
I _{CC}	Supply current, partial operating condition	V _{CC} =5V, T _a =25°C, Output pins open		200	300	μA
I _{LCD}	Liquid crystal supply current, full operating condition	V _{CC} -V _{LCD} =4.2V, T _a =25°C, Output pins open		60	120	μA
C _I	Input capacitance	V _{CC} =V _I =V _O =V _{SS} , f=1MHz, 25mVrms		7	10	pF
C _{I(XIN)}	Oscillator input capacitance	V _{CC} =X _{OUT} =V _{SS} , f=1MHz, 25mVrms		7	10	pF
V _{BD}	Battery voltage detection voltage range (Note 2)	10kΩ ≤ R _{BD} ≤ 200kΩ, T _a =25°C	4.5		5.5	V

Note 1. V_{OX} is the medium level of the 3-level output of port COM.

2. The detection resistance R_{BD} is connected between the V_{SS} and pin BDIN.

3. Currents are taken to be positive when flowing into the IC with minimum and maximum values taken as absolute values.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

TIMING REQUIREMENTS ($T_a=0\sim 50^\circ\text{C}$, $V_{CC}=5V\pm 10\%$, $V_{SS}=0V$, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
$t_{SU}(K-X_{IN})$	Data setup time before clock input, port K inputs	$f_\phi = 525\text{ kHz}$ (Note 1)	0			μS
$t_{SU}(S-X_{IN})$	Data setup time before clock input, port S inputs		0			μS
$t_{SU}(INT_A-X_{IN})$	Data setup time before clock input, INT_A input		0			μS
$t_{SU}(INT_B-X_{IN})$	Data setup time before clock input, INT_B input		0			μS
$t_h(K-X_{IN})$	Data hold time after clock input, port K inputs		0.4			μS
$t_h(S-X_{IN})$	Data hold time after clock input, port S inputs		0.4			μS
$t_h(INT_A-X_{IN})$	Data hold time after clock input, INT_A input		0.4			μS
$t_h(INT_B-X_{IN})$	Data hold time after clock input, INT_B input		0.4			μS

Note 1. $f_\phi = 1/8 f_{XIN}$ which corresponds to the internal clock frequency

SWITCHING CHARACTERISTICS ($T_a=0\sim 50^\circ\text{C}$, $V_{CC}=5V\pm 10\%$, $V_{SS}=0V$, unless otherwise noted)

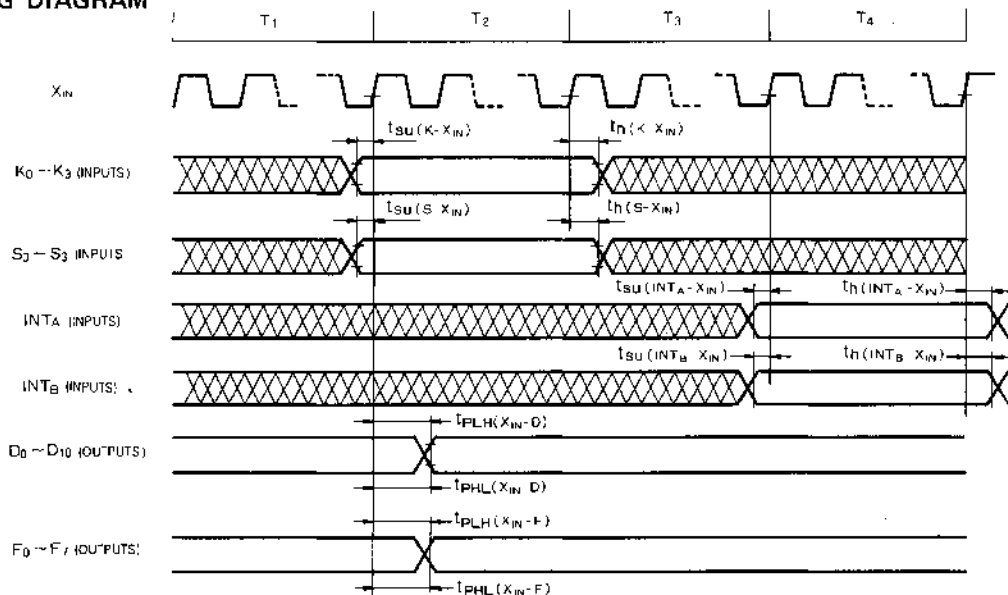

5

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
$t_{PLH}(X_{IN}-D)$	Low-to-high-level propagation time from clock input to port data output, port D	$f_\phi = 525\text{ kHz}$ $R_L = 20\text{ k}\Omega$ $C_L = 100\text{ pF}$ (Note 2)		0.7	1.5	μS
$t_{PLH}(X_{IN}-F)$	Low-to-high-level propagation time from clock input to port data output, port F, K, and S			0.7	1.5	μS
$t_{PHL}(X_{IN}-D)$	High-to-low-level propagation time from clock input to port data output, port D			2.2	3.0	μS
$t_{PHL}(K-X_{IN}-F)$	High-to-low-level propagation time from clock input to port data output, port F, K, and S			2.2	3.0	μS

Note 2. Measurement circuit

TIMING DIAGRAM

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

BASIC TIMING CHART (Note 2)

- Note 1: Internal clock signal which is 1/8 of basic oscillation frequency.
- Note 2: indicates an invalid signal input.

INSTRUCTION FETCH TIMING

- Note 3: Instruction fetch time can differ depending on the types of the instructions.
- Note 4: The instruction which was fetched in the preceding cycle is executed.
- Note 5: The execution of the instruction and addressing of ROM and RAM are performed simultaneously.

I/O INSTRUCTION EXECUTION TIMING

- Note 6: When an OTRO instruction is executed, the output is latched.
- Note 7: Output voltage of port LC depends upon power supply V_{LC0} for the liquid crystal display.
- Note 8: Output voltage of port COM has 3 levels depending on the power supply V_{LC0} for the liquid crystal display.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

BRANCH AND SUBROUTINE CALL INSTRUCTION EXECUTION TIMING (Note 1)

Machine cycle State		M _i				M _{i+1}				M _{i+2}			
		T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄
Instruction B_{xy} (to be operated as the branch instruction, when the instruction BM or BMA was not executed before).													
Program counter			(PC _L) ← xy		(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L) + 1			
ROM address			(ROM address) ← (PC)					(ROM address) ← (PC)					
Execution of program		Execution of the branch instruction				Execution of the instruction stored in the branched address							
Instruction B_{xy} (to be operated as the branch instruction to page 15, when the instruction BM or BMA was executed before).													
Program counter			(PC _L) ← 15		(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L) + 1			
ROM address			(PC _L) ← xy					(ROM address) ← (PC)					
Execution of program		Execution of the branch instruction				Execution of the instruction stored in the branched address on page 15							
Instruction BM_{xy} (subroutine call instruction).													
Program counter			(PC _L) ← 14		(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L) + 1			
ROM address			(PC _L) ← xy		(ROM address) ← (PC)			(ROM address) ← (PC)					
Stack register			(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC)										
Execution of program		Execution of the subroutine call instruction				Execution of the instruction stored in the subroutine called address							
Instruction BL p, xy (branch instruction).													
Program counter			(Temporary register) ← p		(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L) + 1			
ROM address			(ROM address) ← (PC)			(PC _H) ← (Temporary register)	(PC _L) ← xy	(PC _L) ← (PC _L) + 1		(ROM address) ← (PC)			
Execution of program		Page number is stored temporarily				Execution of branch instruction				Execution of the instruction stored in the branched address			
Instruction BML p, xy (subroutine call instruction).													
Program counter			(Temporary register) ← p		(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L) + 1			
ROM address			(ROM address) ← (PC)			(PC _H) ← (Temporary register)	(PC _L) ← xy	(PC _L) ← (PC _L) + 1		(ROM address) ← (PC)			
Stack register						(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC)							
Execution of program		Page number is stored temporarily				Execution of the subroutine call instruction				Execution of the instruction stored in the subroutine called address			

5

Note 1 The instructions BA, BMA, BLA and BMLA have the same execution timing as B, BM, BL and BML respectively as shown. The only difference is that (PC_L) ← xy is replaced by (PC_L) ← x(A).

INTERRUPT EXECUTION TIMING (Note 2)

Machine cycle State		M _{i-1}	M _i				M _{i+1}				M _{i+2}				
		T ₄	T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄	
Interrupt request input	INT _A (Note 3)		[X]					[X]				[X]			
Program counter	(PC)					(PC _L) ← (PC _L) + 1					(PC _L) ← (PC _L)				(PC _L) ← (PC _L) + 1
ROM address				(ROM address) ← (PC)					(ROM address) ← (PC)				(ROM address) ← (PC)		
Stack register											(SK ₂) ← (SK ₁) ← (SK ₀) ← (PC)				
Execution of program											no execution (skip)				

Note 2 When the instruction executed in the machine cycle M_{i+1} is a BL, BML, BLA or BMLA, the value of address 2 of page 0 is stored in the program counter during M_{i+3}.
 Note 3 The interrupt request input INT_B has the same execution timing as INT_A. If the input is low level in the machine cycle M_{i-1} and high level in the machine cycle M_i, the interrupt is executed during the interrupt enable state.

MITSUBISHI MICROCOMPUTERS M58497-XXXP

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

DESCRIPTION

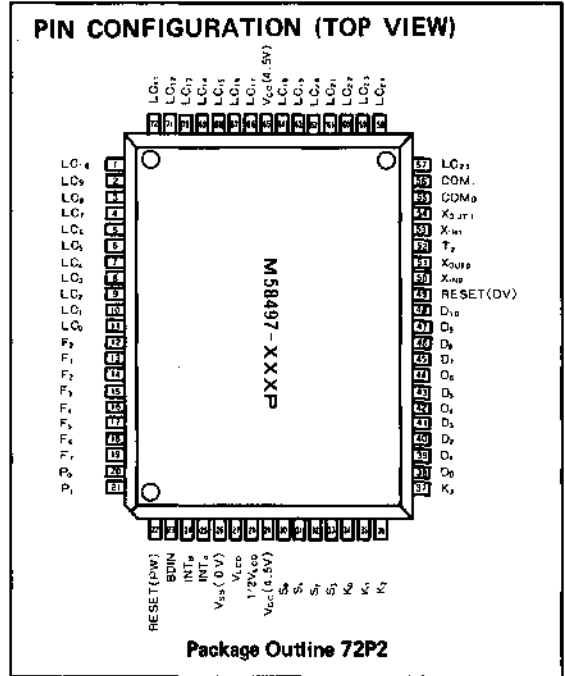

The M58497-XXXP is a single-chip 4-bit microcomputer fabricated using CMOS technology. Its features are liquid crystal display direct drive circuit, current saving circuit for back-up of a 15-stage frequency divider and RAM.

The device is designed for applications in which clock and liquid crystal display functions are included and where the low-power dissipation achieved by CMOS is especially important.

FEATURES

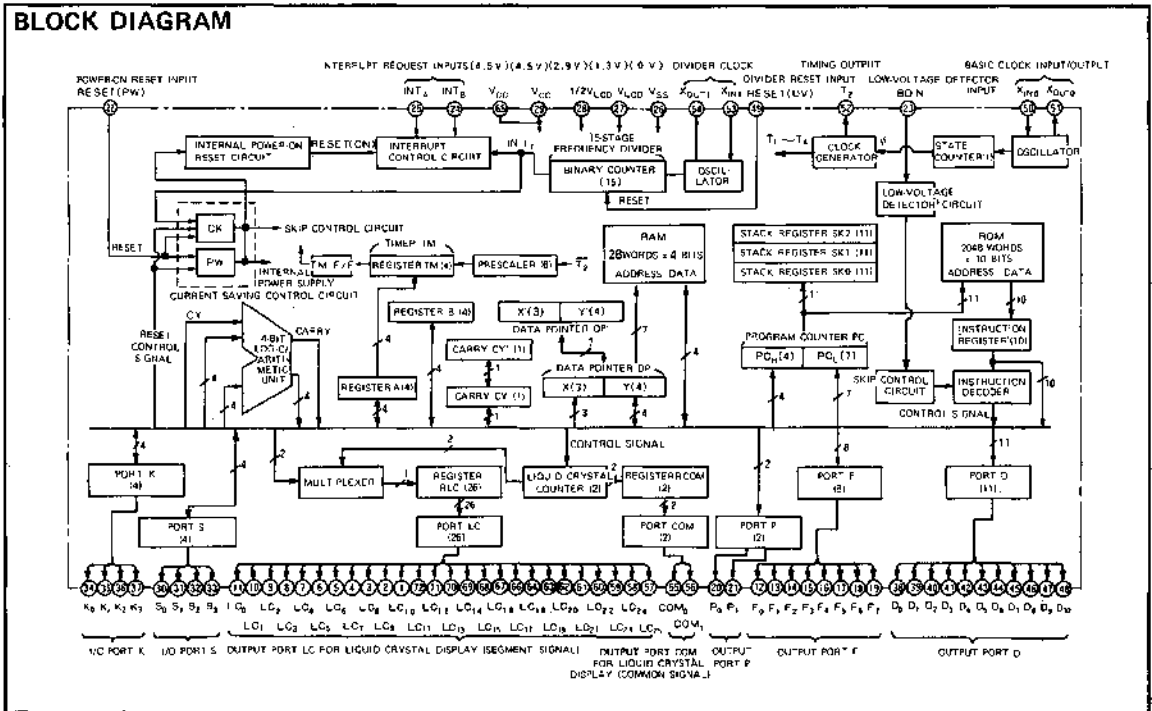

- Basic machine instructions 77
- Instruction execution time (at an oscillation frequency of 455kHz) 17.6μs
- Memory capacity: ROM: 2048 words x 10 bits
Internal RAM: .. 128 words x 4 bits
External RAM: .. 256 words x 4 bits
- Single 4.5V power supply
- Internal oscillator circuit
- Internal 15-stage frequency divider
- Internal current saving circuit
- Internal low-voltage detector circuit
- Subroutine nesting 3 levels
- Internal timer: Prescaler: 6 bits
Timer: 4 bits
- Output ports for liquid crystal display
Segment signals (port LC) 26 bits
Common signals (port COM) 2 bits

PIN CONFIGURATION (TOP VIEW)

- I/O ports (ports K and S) 2 x 4 bits
- Output port (port D) 11 x 1 bit
- Output port (port F) 8 x 1 bit
- Output port (port P) 2 x 1 bit
- Interrupt function 4 factors, 1 level

BLOCK DIAGRAM

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

APPLICATIONS

- Electronic tuners for radios and TVs
- Medical equipment
- Measurement instruments
- Vending machines

FUNCTION

The M58497-XXXP consists of a 2,048 word x 10-bit mask ROM, 128 word x 4-bit RAM, 4-bit arithmetic logic unit, oscillator circuit, 15-stage frequency divider, power saving backup circuit for the RAM memory, low-voltage detector circuit, 4-bit timer, interrupt circuit, and liquid crystal display direct drive circuit. By connecting external 256-word x 4-bit CMOS RAMs to this 4-bit microcomputer, RAM capacity can be easily expanded.

The ROM is capable of storing 16 pages of 128 words of program, addresses being specified by the program counter. The program counter consists of a 7-bit address designating counter and a 4-bit page designating counter. Wrap-around to address zero is automatic after exceeding the address 127. The return address from subroutines and interrupts is stored in a stack register of 11 bits x 3 levels.

When an interrupt request has occurred, control is transferred to a fixed address as follows. In the case of internal power-on reset (RESET(ON)), the program is set to page 0, address 0, for the INT_A signal it is set to page 0, address 2, for the INT_B signal it is set to page 0, address 4,

and for the output signal INT_T (1 second signal) of the 15-stage frequency divider, it is set to page 0, address 8.

The internal RAM is configured as 8 files of 16 words, addressed by the 7-bit data pointer. A 16 file x 16 digit external expansion memory can be addressed using 8 bits of address composed of the 4-bit register Y and 4-bit register B.

RAM addressing, register-to-register transfers, RAM-accumulator transfers, arithmetic operations, input/output operations, and timer operations are performed chiefly through the 4-bit register A (accumulator).

The current saving circuit used in conjunction with the 15-stage frequency divider and RAM can be controlled by the RESET (PW) input and program instructions.

The low-voltage detector circuit is operative when using a battery power source, and can be program controlled to provide an appropriate output upon sensing a low voltage level.

Direct drive of a liquid crystal display is possible using the 26 LC pins and 2 COM pins. 1/2 duty cycle and 1/2 bias or static drive is possible.

The output port D consists of 11 individually latched bits, and in addition to the ability to output a single bit, the position of which is determined by the contents of the data point register Y, 8 bits of the port D can be used as the external RAM address signal output.

Output port F consists of 8 individually latched bits that can be used to output data. It can be set or reset using program instructions.

5

PERFORMANCE SPECIFICATIONS

Parameter		Performance	
Number of basic instructions		77	
Execution time of basic instructions (one-word instruction)		17.6µs (V _{CC} =4.5V, f=455kHz)	
Clock frequency		120~260kHz	
Memory capacity	ROM	2,048 words x 10 bits	
	Internal RAM	128 words x 4 bits	
	External RAM	256 words x 4 bits	
I/O ports	LC	Liquid crystal display output	
	COM	Liquid crystal display output	
	K	Input	4 bits
		Output	4 bits
	S	Input	4 bits
		Output	4 bits
	D	Output	11 x 1 bit
	F	Output	8 x 1 bit
P	Output	2 x 1 bit	
Frequency divider		15-stage built-in divider	
Current saving circuit		Built-in	
Low-voltage detector circuit		Built-in	
Subroutine nesting		3 levels (including 1 level of interrupt)	
Interrupt requests		4 factors, 1 level	
Clock generator circuit		Built-in (for use with 455kHz ceramic filter externally connected)	
Input/output ports	Output voltage	6V (max)	
	Output current (I _{OL})	1.8mA (min)	
Supply voltages	V _{CC}	4.5V (nom)	
	V _{SS}	0V	
	Liquid crystal display driving voltage V _{LCR}	1.3V (nom)	
Element structure		CMOS	
Package		72-pin plastic molded flat package	
Power dissipation (open output terminals)	In full operation	2mW (nom) (V _{CC} =4.5V, f=455kHz)	
	Divider and RAM in the idle state	90µW (nom) (V _{CC} =4.5V, f=455kHz)	

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Output port P consists of 2 pins through which a synchronous signal of one machine cycle width can be output by program instructions.

Seven bits of output port F and P can be used to directly fetch the immediate field of the ROM.

The I/O ports K and S consist of 4 bits through which data can be transferred to and from register A.

PIN DESCRIPTIONS

Pin	Name	Input or output	State at reset (internal power-on)	Function
X _{IN0}	Clock oscillator input	Input	—	These are the clock input and output pins. A ceramic element or other frequency-determining element is connected between pins X _{IN0} and X _{OUT0} . When an external clock is used, connect the clock source to the X _{IN0} pin and leave the X _{OUT0} pin open.
X _{OUT0}	Clock oscillator output	Output	—	
X _{IN1}	Divider clock input	Input	—	These are the divider clock input and output pins. The quartz crystal that determines the reference oscillation frequency is connected between pins X _{IN1} and X _{OUT1} .
X _{OUT1}	Divider clock output	Output	—	
RESET _(DIV)	Divider reset input	Input	—	This is the divider reset input for the 15-stage divider circuit used to divide the 32k Hz crystal reference signal.
BDIN	Low-voltage detector input	Input	—	A built-in low-voltage detector circuit has been provided. A resistor should be connected to the BDIN pin for voltage sensing.
INTA	Interrupt request A signal	Input	Interrupt disable	These input signals are for an interrupt request. The request is accepted on the rising edge of the signal. In addition to these external input signals, an interrupt request INT _T from the 15-stage frequency divider output signal is also treated as an interrupt.
INTB	Interrupt request B signal	Input	Interrupt disable	
LC ₀ ~ LC ₅	Liquid crystal display segment outputs	Output	—	These liquid crystal display outputs are suitable for driving a liquid crystal display at 1/2 duty cycle and 1/2 bias. The output ports for direct drive of such liquid crystal displays are port LC (LC ₀ ~ LC ₅) for the segments and port COM (COM ₀ ~ COM ₁) for the common outputs.
COM ₀ ~ COM ₁	Liquid crystal display common outputs	Output	—	
V _{LC0} , 1/2 V _{LC0}	Power supply for liquid crystal display	—	—	These are the liquid crystal display power supply pins for segment signals and common signals.
D ₀ ~ D ₁₀	Output port D	Output	High level	This output port consists of 11 bits, each of which is individually latched and can be selected to be set or reset according to the contents of register Y. In addition, 8 bits of this port can be used to fetch an 8-bit address for external RAM.
F ₀ ~ F ₇	Output port F	Output	High level	This output port consists of 8 bits, each of which is individually latched and can be set or reset using machine instructions.
P ₀ , P ₁	Output port P	Output	High level	This output port consists of 2 bits from which one synchronous signal of one machine cycle width can be output per instruction. The 7-bit immediate field of an instruction can be output through this port in combination with 5 bits of port F.
K ₀ ~ K ₃	Input/output port K	Input/output	High level	Ports K and S are 4-bit latched input/output ports through which data can be transferred to and from register A (accumulator). When the output is programmed high, the high-impedance state is enabled allowing use of the pins as input pins.
S ₀ ~ S ₃	Input/output port S	Input/output	High level	
T ₂	Timing output	Output	—	This timing output is used for testing the device.
RESET _(PW)	Power-on reset input	Input	Low level	When the internal power supply is switched on, a built-in automatic reset circuit generates a high-level reset signal that resets the I/O ports and starts the system.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

DESCRIPTION OF BASIC FUNCTIONAL BLOCKS
Program Counter PC

The program counter is an 11-bit address register. The 4 high-order bits are used to designate the page number and are as a group called PC_H . The 7 low-order bits are used to designate the address on the page and as a group are called PC_L . The PC designates the address of the 2048 words by 10-bit mask-programmable ROM. The ROM is organized into 16 pages of 128 words. As instructions are fetched from ROM, PC_L is incremented, so that, unless there is a branch, executed instructions are fetched and executed in sequence. Care must be taken when the last instruction on a page (address 127) is executed, because when PC_L is incremented it becomes zero with a carry, but the carry is disregarded so that the next instruction to be fetched will be the instruction at the first address of the same page. Therefore, to move to the next page, PC_H must be modified by using branch instructions such as BL, BML, BLA, and BMLA.

Pages 14 and 15 are special pages set aside to accommodate subroutines. Page 14 can be used to store subroutines, which are callable from pages other than page 14 by using the instructions BM and BMA which can be used as single-instructions to call page 14 subroutines.

When BM or BMA instructions are executed within page 14, they are equivalent to the branch instructions B and BA. When B or BA instructions are executed within page 14, a branch to the specified address on page 15 is executed.

Stack Registers SK₀, SK₁, SK₂

The 3-level stack register consists of 11-bit registers for storing the contents of the program counter when control is transferred from the main program to a subroutine or interrupt. Subroutines can use 3 levels, so that when 1 level is used for an interrupt routine 2 levels are reserved for subroutine nesting.

Data Pointers DP, DP'

The data pointer is used to designate the address of RAM or the bit position of output port D and consists of the 3-bit register X and the 4-bit register Y. The internal RAM is organized as 8 files of 16 words. Register X designates the file and register Y designates the word position of a file or the bit position of the output port D.

The data pointer DP' is selected by software during interrupt processing, leaving the contents of DP saved (unchanged).

The external RAM memory is organized as 16 files of 16 words that can be added to the system to expand memory capacity. Register Y is used to designate the word position of a file while register B designates the file itself.

Register A (Accumulator) and Carry Flags, CY, CY'
Register A is the 4-bit accumulator which forms the heart of the 4-bit microcomputer. Data processing operations such as arithmetic, transfer, exchange, conversion, and input/output operations are executed basically through this register.

The carry flag CY are used to store the carry or borrow from the most significant bit of the arithmetic unit resulting from the execution of various instructions. It can be tested and used for a variety of purposes. In principle, it acts as a 1-bit flag.

The carry flag CY' is used during interrupt processing to save the contents of the carry flag CY.

Register B (Auxiliary Register)

This register consists of a 4-bit register used for temporary storage as well as designate the file number of external RAM.

4-Bit Arithmetic Logic Unit

This unit is used to perform 4-bit arithmetic and logical operations and consists of a 4-bit adder and the associated logic circuitry. It is used to perform operations such as additions, complementing, logical and arithmetic comparisons, and bit manipulation.

Frequency Divider and Timer

A 15-stage frequency divider is used to divide the basic oscillator frequency. It is connected to the oscillator source device through pins X_{IN1} and X_{OUT1} . The frequency divider generates the interrupt request signal INT_T which is input to the interrupt control circuit. It also sets the CK flag for controlling the power saving circuit.

The basic oscillator circuit for the timer is the timing signal T_2 . The timer consists of a 6-bit prescaler and a 4-bit counter. The timer flags TMF/F are set when a timer overflow occurs and sensed by the TTM instruction. The 4-bit timer counter is set by the STM instruction. Prescaler and timer flags are reset at the same time.

Power Saving Circuit

The power saving circuit is controlled by the CK flag and PW. Its output is sent to the built-in power supply reset circuit and causes the generation of an interrupt request signal RESET(ON). Control is unconditionally transferred to address 0 on page 0 and results in the resetting of I/O ports. The interrupt request signal RESET(ON) is generated on the rising edge of the built-in power supply reset output. The built-in power supply may be switched off by means of either an external signal or stop instruction, but power is maintained to the following circuits:

1. Internal data memory (RAM)

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

2. Divider Clock oscillator circuit
3. 15-stage frequency divider
4. Low-voltage detector circuit
5. Power saving circuit

Low-Voltage Detector Circuit

The low-voltage detector circuit is effective when using the M58497-XXXP with a battery power supply. The resistor which is used to determine the low sensing voltage is connected to the BDIN pin. A voltage falling below this level is sensed by the program and can be displayed by using an output port.

Interrupt Functions

Four factors in one level of hardware interrupt functions have been provided. The four interrupt request sources consist of the external interrupt requests INT_A and INT_B , the internal power-on reset output RESET(ON), and the 15-stage frequency divider output INT_T . Interrupt is enabled by the instructions EIA, EIB, and EIT, and disabled by the DIA, DIB, and DIT instructions respectively. Interrupt requests generated by the internal power supply by means of the reset output RESET(ON) cannot be disabled and will cause an unconditional hardware initialization whenever received.

In the interrupt enable state, interrupt requests INT_A and INT_B are accepted on the rising edge of these signals. When an interrupt request is received when interrupt is disabled, interrupt processing does not occur but the interrupt request is stored in a latch so that when the interrupt disable condition is cancelled the appropriate interrupt enabling instruction can be used to execute the interrupt routine immediately.

One level of the 3-level stack register is required when using an interrupt program. This leaves the remaining two levels available for subroutine processing. After an interrupt is processed, control is returned to the main program by means of an instruction such as RTI. Care must be taken, however, after starting an interrupt program to save the content of data pointer DP, register A, carry flag CY, and any other registers used by the interrupt program so that the contents may be restored before returning to the main program.

When an interrupt has been accepted, the micro-computer internal states are as follows.

(1) Program counter

The main program current address is stored in the stack register. Control is transferred to address 0 page 0 by a RESET(ON) interrupt, to address 2 page 0 by an INT_A interrupt to address 4 page 0 by an INT_B interrupt, and to address 8 page 0 by an INT_T interrupt. Note, however, that for the RESET(ON) signal the instruc-

tion on address 0 page 0 is invalid.

(2) Interrupt Enable Flags

If any of the four available interrupt factors are executed, all the interrupt enable flags are reset and the interrupt disable state is entered.

(3) Skip flags

Skip flags have been provided to indicate skip conditions for skip or continuous skip instructions. These are provided for all stacks, the stack flags being saved and the skip condition for an interrupt being held in memory.

General-Purpose I/O Ports K, S, F, P and D

These 4-bit and 1-bit general-purpose registers are used for such operations as data transfers to and from register A, instruction transfers, 1-bit transfers as selected by register Y, storage of the 7-bit immediate field of instructions fetched from ROM, and data transfers between external RAM. Each output circuit is a latched CMOS circuit.

Input/output ports K and S are 4-bit ports, capable of data transfer with register A. When used as input ports, the DIKS instruction is used to reset the output latches.

The output port F consists of an 8-bit port with each bit independently latched. Each bit is settable and resettable by means of the SF and RF instructions respectively.

Output port P is a 2-bit port which is normally at the high level. The instructions SP_0 and SP_1 can be used to generate a low-level synchronous signal for one machine cycle.

Seven bits of the output ports F and P can be used to directly fetch the ROM immediate field value (7 bits) by means of the OTRO instruction.

The output port D consists of 11 bits independently latched. The contents of register Y indicate the individual bit to be set by the SD instruction or to be reset by the RD instruction. The 8-bit address of external memory (RAM) is output by means of this port.

Liquid Crystal Display Drive Circuit

The liquid crystal display direct drive circuit consists of the following units. A block diagram of these units is shown in Fig. 1.

(1) Liquid crystal display control counter

This 2-bit quaternary counter counts down under control of the ELC instruction. The contents of this counter select 1 bit of register A and transfer data sequentially to the segment register RLC by a TLC instruction while determining the frame frequency by means of transferring the contents of the counter to the common register RCOM.

(2) Register A

This 4-bit register serves as an accumulator. Its func-

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

tions include microcomputer processing, control, and central processing for input and output.

(3) Segment Register RLC

This 26-bit serial register is used to store selected single data bit from register A by means of the TLC instruction. It shifts single bit in order and temporarily stores the segment signals for the liquid crystal display.

(4) Common Register RCOM

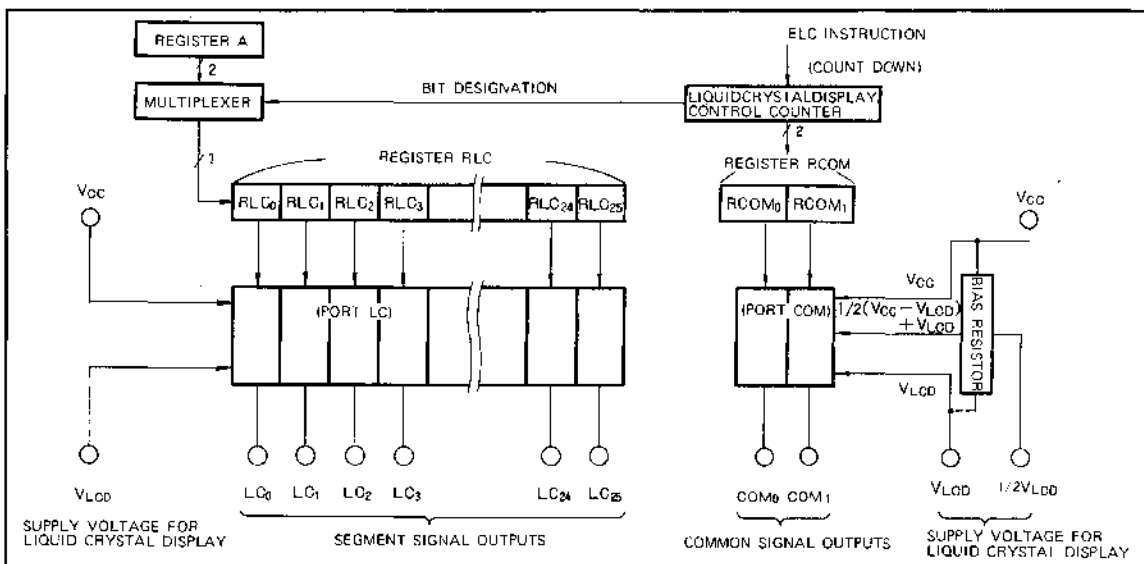

This 2-bit register is used to convert the contents of the liquid crystal display control counter to the common signals required for the display.

(5) Port LC

This 26-bit latched port is used to store data in parallel by means of the ELC or DLC instructions from the segment register RLC. It provides two levels of bias, the liquid crystal drive voltage V_{LCD} and the supply voltage V_{CC} .

(6) Port COM

Port COM consists of 2 latched bits used for parallel storage of data transferred from the common register RCOM by the ELC and DLC instructions. It provides 3 levels of bias including liquid crystal drive voltage (V_{LCD} , $1/2 V_{LCD}$) and the supply voltage V_{CC} .

5

Fig. 1 Liquid crystal display drive circuit block diagram

Reset Function

As shown in Fig. 2, when a low level of at least 10ms is applied to the M58497-XXXP RESET(PW) input pin, all input/output ports are reset and interrupt is disabled. (Refer to the section on Power-on Reset States in the pin descriptions.) Next, when the RESET(PW) input is set to high, the internal power-on reset output RESET(ON) causes the generation of an interrupt and the program counter is set to address 0 on page 0 as the starting address.

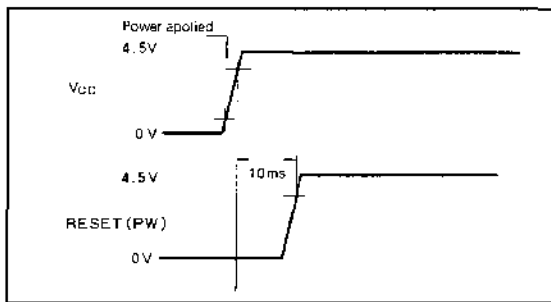

Fig. 2 Power-on reset circuit

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Clock Generator Circuit

A built-in clock generator circuit has been provided for use with a ceramic element connected between the clock input and output pins. In addition, an external clock source may be input at pin X_{IND} , leaving X_{OUT0} open. Circuit examples are shown in Fig. 3 and Fig. 4.

Documentation Required Upon Ordering

The following information should be provided when ordering a custom mask.

- (1) M58497-XXXP mask confirmation sheet
- (2) ROM data 3 EPROM sets
- (3) Oscillation frequency selection
On confirmation sheets
- (4) Frequency divider output selection (1Hz/2Hz)
On confirmation sheets

5

Note 1 This list shows the machine codes and corresponding machine instructions. D₃~D₀ indicate the low-order 4 bits of the machine code and D₇~D₄ indicate the high-order 4 bits. Hexadecimal numbers are also shown that represent the codes. An instruction may consist of one or two words, but only the first word is listed. Code combinations indicated with asterisk (*) and bar () must not be used.

Two-word instructions

	Second word
BL	11 0xxxx yyyy
BLA	11 1xxxx XXXX
BML	10 0xxxx yyyy
BMLA	10 1xxxx XXXX

- Note 1. When a skip has been generated, the next instruction only is invalid and the program counter is not incremented by 2. Therefore, the number of cycles does not change even if a skip is not generated.
2. Instructions Bxy, BAXX, BMxy and BMAXX execute the second function of the functions column when executed, provided that none of the instructions RT, RTS, BL, BML, BLA, or BMLA was executed after the execution of a BM or BMA instruction.

Symbol	Meaning	Symbol	Meaning
A	4-bit register (accumulator)	P(COMn)	Common output port for liquid crystal display
A _i	Indicates the bits of register A, where i = 0~3	P(LCn)	Segment output port for liquid crystal display
B	4-bit auxiliary register	PW F/F	1-bit power supply control flag display
BD _{OUT}	Battery detector signal	R(COMn)	Common register for liquid crystal display (4 bits)
CK F/F	1-bit 1-second flag	R(LCn)	Segment register for liquid crystal display (25 bits)
CY	1-bit carry flag	S	4-bit I/O port
CY'	1-bit carry stack flag	SCA	Output of bit A of control counter for liquid crystal display
D	11-bit output port	SK0	11-bit stack register
D _i	Indicates the bits of port D, where i = 0~3	SK1	11-bit stack register
D(Y)	The bit of port D addressed by Y	SK2	11-bit stack register
DP	7-bit data pointer composed of register Y, X	TM	4-bit timer/counter
Y	4-bit register	TM F/F	1-bit timer/counter flag
X	3-bit register	xx	2-bit binary variable
DP'	7-bit data pointer	yyyy	4-bit binary variable
DET F/F	1-bit battery detector flag	mmm	3-bit binary variable
F	8-bit output port	nnnn	4-bit binary variable
F _i	Indicates the bits of port F, where i = 0~7	ll	2-bit binary variable
K	4-bit I/O port	lll	3-bit binary variable
M(DP)	4-bit data of memory addressed by data pointer DP	XXXX	4-bit unknown binary variable (the value doesn't affect execution)
M _i (DP)	A bit of data of memory addressed by data pointer DP where i = 0~3	←	Indicates direction of data flow
PC	11-bit program counter composed of PC _L , PC _H	{ }	Indicates contents of register memory, etc.
PC _L	Low-order 7 bits of the program counter	∨	Exclusive OR
PC _H	High-order 4 bits of the program counter	∧	AND
P ₀	4-bit output port	-	Negation
P ₁	4-bit output port	x	Indicates flag is unaffected by instruction execution
		xy	Label used to indicate the address
		C	Hexadecimal number C + binary number X
		+	
		x	

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
V _{CC}	Supply voltage	With respect to V _{SS}	-0.3-6.0	V
V _I	Input voltage		-0.3-V _{CC} +0.3	V
V _O	Output voltage		0-V _{CC}	V
P _d	Power dissipation	T _a = 25°C	300	mW
T _{opr}	Operating free-air temperature range		-20-70	°C
T _{stg}	Storage temperature range		-40-125	°C

RECOMMENDED OPERATING CONDITIONS (T_a = -20~70°C, unless otherwise noted)

Symbol	Parameter	Limits			Unit
		Min	Nom	Max	
V _{CC}	Supply voltage	3	4.5	5.5	V
V _{SS}	Supply voltage		0		V
V _{LCD}	Liquid crystal supply voltage		1.3		V
V _{IH}	High-level input voltage	0.7V _{CC}		V _{CC}	V
V _{IL}	Low-level input voltage	0		0.3V _{CC}	V
f _{XIN}	Oscillator frequency	240	455	520	kHz
f _φ	Internal clock oscillator frequency	120		260	kHz

5

ELECTRICAL CHARACTERISTICS (T_a = -20~70°C, V_{CC} = 4.5V, V_{SS} = 0V, f_{XIN} = 455kHz, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
V _{OH}	High-level output voltage, ports D, K, and S	I _{OH} = -10μA	4			V
V _{OH}	High-level output voltage, ports F, and P	I _{OH} = -200μA	2.4			V
V _{OL}	Low-level output voltage, ports D, K, and S	I _{OL} = 1.8mA			0.5	V
V _{OL}	Low-level output voltage, ports F, and P	I _{OL} = 1.8mA			0.5	V
V _{OH}	High-level output voltage, port LC	V _{LCD} = 1.3V, T _a = 25°C	4.3	4.5		V
V _{OH}	High-level output voltage, port COM	V _{LCD} = 1.3V, T _a = 25°C	4.3	4.5		V
V _{OX}	Medium output voltage, port COM (Note 1)	V _{LCD} = 1.3V, T _a = 25°C	2.7	2.9	3.1	V
V _{OL}	Low-level output voltage, port LC	V _{LCD} = 1.3V, T _a = 25°C		1.3	1.5	V
V _{OL}	Low-level output voltage, port COM	V _{LCD} = 1.3V, T _a = 25°C		1.3	1.5	V
I _{CC}	Supply current for full operation	T _a = 25°C, Output pins open		0.4		mA
I _{CC}	Supply current for partial operation	T _a = 25°C, Output pins open		20		μA
C _i	Input capacitance	V _{CC} = V _I = V _O = V _{SS} , f = 1MHz, 25mVrms		7	10	pF
C _{i(XIN)}	Oscillator input capacitance	V _{CC} = X _{OUT} = V _{SS} , f = 1MHz, 25mVrms		7	10	pF
V _{BD}	Battery voltage detection voltage range (Note 2)	10kΩ ≤ R _{BD} ≤ 200kΩ, T _a = 25°C	4		5.5	V

Note 1. V_{OX} is the medium level of the 3-level output of port COM.
 2. The detection resistance R_{BD} is connected between the V_{SS} and BDIN pin.
 3. Currents are taken to be positive when flowing into the IC with minimum and maximum values taken as absolute values.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

TIMING REQUIREMENTS (Ta = -20~70°C, Vcc = 3~5.5V, Vss = 0V, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
t _{SU} (K-XIN)	Data setup time before clock input, port K inputs	f _φ = 230kHz (Note 1)	0			μs
t _{SU} (S-XIN)	Data setup time before clock input, port S inputs		0			μs
t _{SU} (INTA-XIN)	Data setup time before clock input, INT _A input		0			μs
t _{SU} (INTB-XIN)	Data setup time before clock input, INT _B input		0			μs
t _H (K-XIN)	Data hold time after clock input, port K inputs		0.4			μs
t _H (S-XIN)	Data hold time after clock input, port S inputs		0.4			μs
t _H (INTA-XIN)	Data hold time after clock input, INT _A input		0.4			μs
t _H (INTB-XIN)	Data hold time after clock input, INT _B input		0.4			μs

Note 1. t_φ = 1/2 · f_{XIN} which corresponds to the internal clock frequency

SWITCHING CHARACTERISTICS (Ta = -20~70°C, Vcc = 3~5.5V, Vss = 0V, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
t _{PLH} (XIN-D)	Low-to-high level propagation time from clock input to port data output, port D	f _φ = 230kHz		2.2	3	μs
t _{PLH} (XIN-F)	Low-to-high level propagation time from clock input to port data output, ports F, P, C, and S	R _i = 20kΩ		2.2	3	μs
t _{PHL} (XIN-D)	High-to-low level propagation time from clock input to port data output, port D	C _L = 100pF		0.7	1.5	μs
t _{PHL} (XIN-F)	High-to-low level propagation time from clock input to port data output, ports F, P, K, and S	(Note 2)		0.7	1.5	μs

Note 2. Measurement circuit

TIMING DIAGRAMS

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

BASIC TIMING CHART (Note 1)

- Note 1: [X] indicates an invalid signal input.
- 2: internal clock signal which is 1/2 of basic oscillator frequency.

5

INSTRUCTION FETCH TIMING

- Note 3: Instruction fetch time can differ depending on the types of the instructions.
- 4: The instruction which was fetched in the preceding cycle is executed.
- 5: The execution of the instruction and addressing of ROM and RAM are performed simultaneously.

I/O INSTRUCTION EXECUTION TIMING

- Note 6: When an OTRO instruction is executed, the output is latched.
- 7: Output voltage of port LC depends upon power supply V_{CCD} for the liquid crystal display.
- 8: Output voltage of port COM has 3 levels depending on the power supply V_{CCD} for the liquid crystal display.

SINGLE-CHIP 4-BIT CMOS MICROCOMPUTER

Note 1. The instructions BA, BMA, BLA and BMAL have the same execution timing as B, BM, BL and BML, respectively as shown. The only difference is that (PC_i) - xy is replaced by (PC_i) - x(A).

INTERRUPT EXECUTION TIMING (Note 2)

Machine cycle	State	M _{i-1}				M _i				M _{i+1}				M _{i+2}			
		T ₄	T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄	T ₁	T ₂	T ₃	T ₄			
Interrupt request input	INT _A (Note 3)	[X]												[X]			
Program counter	(PC)					(PC _i) - (PC _i) + 1				(PC _i) - (PC _i)				(PC _i) - 0 (PC _i) - 2			
ROM address						(ROM address) ← (PC)				(ROM address) ← (PC)				(ROM address) ← (PC)			
Stack register														(SK ₇) ← (SK ₆) ← (SK ₆) ← (PC)			
Execution of program														no execution (sk-p)			

Note 2. When the instruction executed in the machine cycle M_{i+1} is a BL, BM, BLA or BML, the value of address 2 of page 0 is stored in the program counter during M_{i+2}.

3. The interrupt request input INT_B has the same execution timing as INT_A. If the input is low level in the machine cycle M_{i-1} and high level in the machine cycle M_i, the interrupt is executed during the interrupt enable state.

MELP S8-48 MICROCOMPUTERS

6

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

DESCRIPTION

The MELPS 8-48 LSI family is a low-cost high-performance single-chip microcomputer series. The functions have been integrated. For example the CPU, ROM, RAM, I/O ports, timer and other circuits are all on one chip. The MELPS 8-48 family has the following three configurations to meet the requirements of different applications for various ROM and RAM capacities.

M5L8048-XXXX

ROM 1024 bytes
RAM 64 bytes
I/O 27 pins

M5L8049-XXXX

ROM 2048 bytes
RAM 128 bytes
I/O 27 pins

M5L8748S

EPROM 1024 bytes
RAM 64 bytes
I/O 27 pins

Timer and interrupt inputs are also built into these chips. The program memory capacity can easily be expanded to 4K bytes. The M5L8243P input/output expander chip can be used to extend the I/O capability. The family of microcomputers allows designers to fabricate systems for applications simply and quickly.

The M5L8048-XXXX contains 1K bytes of read only memory and the M5L8049-XXXX contains 2K bytes. The contents of the memory is set by a mask during manufacture. This makes it practical to mass produce ROMs containing customer developed programs.

The M5L8748S contains 1K bytes of EPROM and is pin-compatible with the M5L8048-XXXX. Its memory can be electrically written and changed by the user. This chip can be used while a system is being developed and subject to modifications. Once the system has been checked out and the program debugged, the program can be masked in the M5L8048-XXXX.

A cross assembler, the MELPS 8-48, is available for use with this family of microcomputers. Designers will find the assembler convenient and easy to use.

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

BASIC FUNCTION BLOCKS

Program Memory (ROM)

The M5L8048-XXXP and M5L8748S contain 1024 bytes of ROM, in the case of the M5L8748S, it is EPROM and its contents can easily be changed by the user. The M5L8049-XXXP contains 2048 bytes of ROM. The program for the users application is stored in this ROM. Addresses 0, 3, 7 of the ROM are reserved for special functions. Table 1 shows the meaning and function of these three special addresses.

Table 1 Reserved, defined addresses and their meanings and functions

Address	Meaning and function
0	The first instruction executed after a system reset.
3	The first instruction executed after an external interrupt is accepted.
7	The first instruction executed after a timer interrupt is accepted.

The ROM can be used to store constants and other 8-bit fixed data in addition to the program. Instructions such as MOVP A, @A and MOVP3 A, @A can be used to access the constants and data. The data could be in the form of tables, and can be easily looked up.

Data Memory (RAM)

The M5L8048-XXXP and M5L8748S contain 64 bytes of RAM. The M5L8049-XXXP contains 128 bytes of RAM. The RAM is used for data storage and manipulation and is divided into sections for more efficient processing. Addresses 0~7 and 24~31 form two banks of general purpose registers that can be directly addressed. Addresses 0~7 compose bank 0 and are numbered R0~R7. Addresses 24~31 compose bank 1 and are also numbered R0~R7. Only one bank is active at a time. The instructions SEL RB0 and SEL RB1 are used to select the working bank. Fig. 1 shows the division of the RAM and its mapping.

Addresses 8~23 compose an 8-level program counter stack. The details for using the stack will be found in the "Program Counter and Stack" section. Please refer to that section for details.

The remaining section, addresses 32 and above, must be accessed indirectly using the general-purpose registers R0 or R1. Of course all addresses can be indirectly addressed using the general-purpose registers R0 and R1.

A good practice to simplify programming is to reserve general-purpose register bank 0 for use of the main program and register bank 1 for interrupt programs. For example if register bank 0 (addressed 0~7) is reserved for processing data by the main program, when an interrupt is accepted the first instruction would be to switch the working registers from bank 0 to bank 1. This would save the data of the main program (addresses 0~7). The interrupt program

can then freely use register bank1 (addresses 24~31) without destroying or altering data of the main program. When the interrupt processing is complete and control is returned to the main program by the RETR instruction, register bank 0 (in this example) is automatically restored as the working register bank at the same time the main program counter is restored.

Addresses 0~31 have special functions, but when not all of the registers are required, the ones not needed can be used for general storage. This includes both banks of general-purpose registers and the stack.

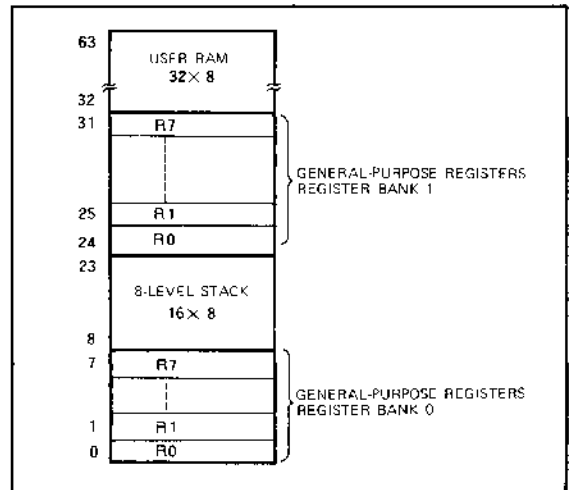

Fig. 4 Data memory (RAM)

PROGRAM COUNTER (PC) AND STACK (SK)

The MELPS 8-48 program counter is composed of a 12-bit binary counter as shown in Fig. 5. The low-order 10 bits can address 1024 bytes of memory. When the high-order 2 bits are zero, the internal, on chip memory is accessed. The high-order 2 bits can have the values 1~3, which allows the user to add up to three banks of 1024 bytes. The program counter can address up to 4096 bytes of memory.

Addresses 8~23 of RAM are used for the stack (program counter stack). The stack provides an easy and automatic means of saving the program counter and other control information when an interrupt is accepted or a subroutine is called. For example, if control is with the main program and an interrupt is accepted, the contents of the 12-bit PC (program counter) is saved in the top of the stack, so it can be restored when control is returned to the main program. In addition to the PC, the high-order 4 bits of the PSW (program status word) are saved in the stack and restored along with the PC. A total of 16 bits are saved, the 12-bit

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

PC and 4 bits of the PSW. A 3-bit stack pointer is associated with the stack. This pointer is a part of the PSW and indicates the top of the stack. The stack pointer indicates the next empty location (top of the stack), in case of an empty stack the top of the stack is the bottom of the stack. The data memory addresses associated with the stack pointer along with the data storage sequence are shown in Fig. 6.

Fig. 5 Program counter

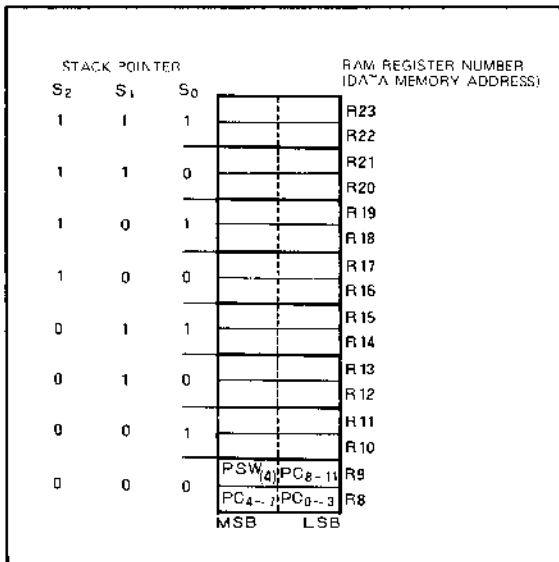

Fig. 6 Relation between the program counter stack and the stack pointer

PROGRAM STATUS WORD (PSW)

The PSW (program status word) is stored in 8 bits of register storage. The configuration of the PSW is shown in Fig. 7. The high-order 4 bits of the PSW are stored in the stack, along with the PC, when an interrupt is accepted or a subroutine call executed. When control is returned to the main program by RETR both the PC and the high-order 4 bits of PSW are restored. When control is returned by RET only the PC is restored, so care must be taken to assure that the contents of the PSW was not unintentionally changed.

The order and meaning of the 8 bits of the PSW are shown below.

- Bit 0~2: Stack pointer (S₀, S₁, S₂)
- Bit 3: Unused (always 1)
- Bit 4: Working register bank indicator
 - 0 = Bank 0
 - 1 = Bank 1
- Bit 5: Flag 0 (value is set by the user and can be tested)
- Bit 6: Auxiliary carry (AC) (it is set/reset by instructions ADD and ADC and used by instruction DA A).
- Bit 7: Carry bit (C) (indicates an overflow after execution)

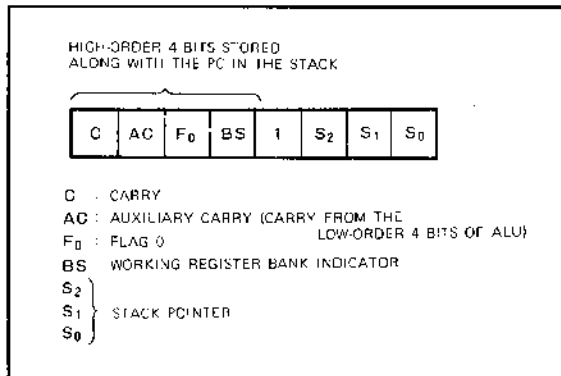

Fig. 7 Program status word

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

I/O PORTS

The MELPS 8-48 has three 8-bit ports, which are called data bus, port 1 and port 2.

Port 1 and Port 2

Ports 1 and 2 and both 8-bit ports with identical properties. The output data of these ports are retained and do not change until another output is loaded into them. When used as inputs the input data is not retained so the input signals must be maintained until an input instruction is executed and completed.

Ports 1 and 2 so-called quasi-bidirectional ports have a special circuit configuration to accomplish this. The special circuit is shown in Fig. 8. All terminals of ports 1 and 2 can be used for input or output.

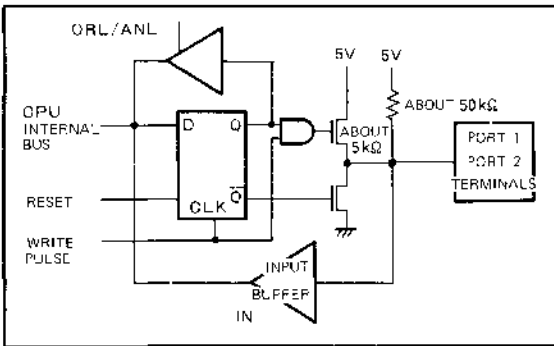

Fig. 8 I/O ports 1 and 2 circuit

Internal on chip pull-up resistors are provided for all the ports. Through the use of pull-up resistors, TTL standard high-level or low-level signals can be supplied. Therefore each terminal can be used for both input and output. To shorten switching time from low-level to high-level, when 1s are output, a device of about 5kΩ or lower is inserted for a short time (about 500ns when using a 6MHz crystal oscillator).

A port used for input must output all 1s before it reads the data from the input terminal. After resetting, a port is set to an input port and remains in this state, therefore it is not necessary to output all 1s if it is to be used for input. In short a port being used for output must output 1s before it can be used for input.

The individual terminals of quasi-bidirectional ports can be used for input or output. Therefore some terminals can be in the input mode while the remaining terminals of a port are in the output mode. This capability of ports 1 and 2 is convenient for inputting or outputting 1-bit or data with few bits. The logical instructions ANL and ORL can easily be used to manipulate the input or output of these ports.

Data Bus (Port 0)

The data bus is an 8-bit bidirectional port, which is used with I/O strobed signals. When the data bus is used for output the output data is latched, but if it is used for input the data is not latched. Unlike ports 1 and 2, which can have individual terminals in the input or output mode, all terminals of the data bus are in the input or output mode.

When the data bus is used as a static port the OUTL instruction can be used to output data and the INS instruction to input data. Strobe pulse \overline{RD} is generated while the INS instruction is being executed or \overline{WR} while OUTL is being executed.

The data bus read/write using MOVX instructions, but then the data bus is a bidirectional port. To write into the data bus a \overline{WR} signal is generated and the data is valid when \overline{WR} goes high. When reading from the data bus, an \overline{RD} signal is generated. The input levels must be maintained until \overline{RD} goes high. When the data bus is not reading/writing, it is in the high-impedance state.

CONDITIONAL JUMPS USING TERMINALS T_0 , T_1 and \overline{INT}

Conditional jump instructions are used to alter program depending on internal and external conditions (states). Details of the jump instructions for the MELPS 8-48 can be found in the section on machine instructions.

The input signal status of T_0 , T_1 and \overline{INT} can be checked by the conditional jump instructions. These input terminals, through conditional jump instructions such as JTO and JNTO, can be used to control a program. Programs and processing time can be reduced by being able to test data in input terminal rather than reading the data into a register and then testing it in the register.

Terminal T_0 , T_1 and \overline{INT} have other functions and uses that are not related to conditional jump instructions. The details of these other functions and uses can be found in the section on terminal functions.

6

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

INTERRUPT

The CPU recognizes an external interrupt by a low-level state at the $\overline{\text{INT}}$ terminal. A "Wired-OR" connection can be used for checking multiple interrupts.

The $\overline{\text{INT}}$ terminal is tested for an interrupt request at the ALE signal output of every machine cycle. When an interrupt is recognized and accepted, control is transferred to the interrupt handling program. This is accomplished by an unconditional jump to address 3 of program memory, which is the start of the interrupt handling program, at the same time the program counter and 4 high-order bits of PSW are automatically moved to the top of the stack.

The interrupt level is one, so the next interrupt cannot be accepted until the current interrupt processing has been completed. The RETR instruction terminates the interrupt processing. That is to say, the next interrupt can not be accepted until the RETR instruction is executed. The next interrupt can be accepted at the start of the second cycle of the RETR instruction (2-cycle instruction). Time/event counter overflow which causes an interrupt request also will not be accepted.

After the processing for an interrupt is completed control is returned to the main program. This is accomplished by executing RETR which restores the program counter and PSW automatically and checks $\overline{\text{INT}}$ and the time/event counter overflow for an interrupt request. If there is an interrupt request, the control will not be returned to the main program but will be transferred to the interrupt handling program.

An external interrupt has a higher priority than a timer interrupt. This means that, if an external and timer interrupt request are generated at the same time, the external interrupt has the priority and will be accepted first.

When a second level of external interrupt is required, the timer interrupt, if not being used, can provide this. The procedure for this is to first disable the timer interrupt, set the timer/event counter to FF_{16} and put the CPU in the event counter mode. After this has been done, if T_1 input is changed to low-level from high-level, an interrupt is generated in address 7.

Terminal $\overline{\text{INT}}$ can also be tested using a conditional jump instruction. For more details on this procedure, check the "Conditional Jumps Using Terminals T_0 , T_1 and $\overline{\text{INT}}$ " section.

TIMER/EVENT COUNTER

The timer/event counter for the MELPS 8-48 is an 8-bit counter, that is used to measure time delays or count external events. The same counter is used to measure time delays or count external events by simply changing the input to the counter.

The counter can be initialized by executing an MOV T, A instruction. The value of the counter can be read for checking by executing an MOV A, T instruction. Reset will stop the counting but the counter is not cleared, so counting can be resumed.

The largest number the counter can contain is FF_{16} . If it is incremented by 1 when it contains FF_{16} , the counter will be reset to 0, the overflow flag is set and a timer interrupt request is generated.

The conditional jump instruction JTF can be used to test the overflow flag. Care must be used in executing the JTF instruction because the overflow flag is cleared (reset) when executed. When a timer interrupt is accepted, the control is transferred to address 7 of program memory.

When both a timer and external interrupt request are generated at the same time, the external interrupt is given priority and will be accepted first by automatically jumping to address 3 of program memory. The timer interrupt request is kept and will be processed when the external interrupt has been completed and a PETR is executed. A latched timer interrupt request is cancelled when a timer interrupt request is generated. A timer interrupt request can be disabled by executing a DIS TCNT1 instruction.

The STRT CNT instruction is used to change the counter to an event counter. Then terminal T_1 signal becomes the input to the event counter and an event is counted each full cycle (low-high-low one event). The maximum rate that can be counted is one time in 3 machine cycles (7.5 μs when using 6MHz crystal). The high-level at T_1 must be maintained at least 1/5 of the cycle time (500ns when using 6MHz crystal).

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

The **START T** instruction is used to change the counter to a timer. The internal clock signal becomes the input to the timer. The internal clock is 1/32 of 400kHz (when using 6MHz crystal) or 12.5kHz. The timer is therefore counted up every 80 μ s. Fig. 9 shows the timer/event counter.

The counter can be initialized by executing an **MOV T, A** instruction. The timer can be used to measure 80 μ s~20ms in multiples of 80 μ s. When it is necessary to measure over 20ms (maximum count 256x80 μ s) of delay time the number of overflows, one every 20ms, can be counted by the program. To measure times of less than 80 μ s; external clock pulses can be input through **T₁** while the counter is in the event counter mode. Every third (or more) **ALE** signal can be used instead of an external clock.

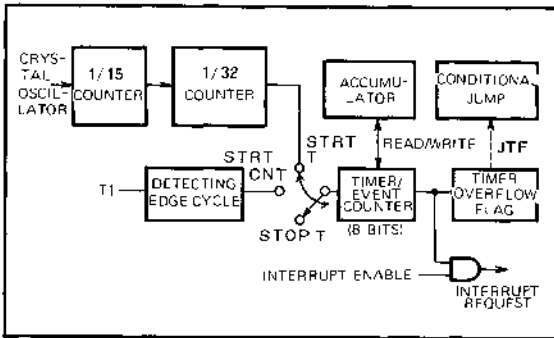

Fig. 9 Timer/event counter

MELPS 8-48 CYCLE TIMING

The output of the state counter is 1/3 the input frequency from the oscillator. When a 6MHz crystal is used for input, the output would be 2MHz (500ns). A **CLK** signal is generated every 500ns (one state cycle) which is used for the demarcation of each machine state. The instruction **ENTO CLK** will output the **CLK** signal through terminal **T₀**. The input of the cycle counter is **CLK** (state cycle) and the output is an **ALE** signal which is generated every 5 state cycles.

Fig. 11 Shows the relationship between clock and generated cycles.

One machine cycle contains 5 states with a **CLK** signal for demarcation of each state. The MELPS 8-48 instructions are executed in one machine cycle or two machine cycles. An instruction cycle can be one or two machine cycles as shown in Fig. 12.

Fig.12 Instruction execution timing

6

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

RESET

The reset terminal is for resetting the CPU. A Schmitt trigger circuit along with a pull-up register are connected to it on the chip. A reset can easily be generated by attaching a $1\mu\text{F}$ as capacitor as shown in Fig. 13. An external reset pulse applied at $\overline{\text{RESET}}$ must remain at low-level for at least 50ms after power has been turned on and reached its normal level.

The reset function causes the following initialization within the CPU.

1. Program counter is reset to 0.
2. Stack pointer is reset to 0.
3. Register bank is reset to 0.
4. Memory bank is reset to 0.
5. Data bus is cleared to high-impedance state.
6. Ports 1 and 2 are reset to input mode.
7. External and timer interrupts are reset to disable state.
8. Timer is stopped.
9. Timer overflow flag is cleared.
10. Flags F_0 and F_1 are cleared.
11. Clock output for terminal T_0 is disabled.

Note 1. On the M5L8748S the $\overline{\text{RESET}}$ terminal, in addition to being used for the reset function, is also used when reading and writing data in the EPROM on the chip. Details on this will be found in the section on reading and writing data in the M5L8748S.

Fig. 13 Example of a reset circuit

SINGLE-STEP OPERATION

The terminal $\overline{\text{SS}}$ on the MELPS 8-48 is provided to facilitate single-step operation. In single-step operation, the CPU stops after the execution of each instruction is completed and the memory address (12 bits) of the next instruction to be fetched is output through the data bus (8 bits) plus the low-order 4 bits of port 2 ($P_{20}\sim P_{23}$). The user can use this to trace the flow of this program instruction by instruction and will find this an aid in program debugging. Single-step operation is controlled through $\overline{\text{SS}}$ and ALE as shown in Fig. 14.

Fig. 14 Single-step operation circuit and timing

A type D flip-flop with preset and reset terminals, as shown in Fig. 11, is used to generate the signal for $\overline{\text{SS}}$. When the preset terminal goes to low-level, $\overline{\text{SS}}$ goes to high-level, which puts the CPU in RUN mode. When the preset terminal is grounded it goes to high-level. Then $\overline{\text{SS}}$ goes to low-level. When $\overline{\text{SS}}$ goes to low-level, the CPU stops. Then when the push-button switch is pushed, a pulse is sent to the clock terminal of the type D flip-flop which turns $\overline{\text{SS}}$ to high-level. When $\overline{\text{SS}}$ goes to high-level the CPU fetches the

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

next instruction and begins to execute it, but then an ALE signal is sent to the reset terminal of the type D flip-flop which turns \overline{SS} to low-level. The CPU again stops as soon as execution of the current instruction is completed. When the push-button switch is again pushed, the cycle is repeated and the CPU is in single-step operation as shown in Fig. 12. While the CPU is stopped in single-step operation, the data bus and the low-order 4 bits of port 2 are used to output the memory address of the next instruction to be fetched. This interferes with input and output, but essential input/output can be latched by using the rising edge of ALE as clock.

Central Processing Unit (CPU)

Central Processing Unit (CPU) is composed of an 8-bit parallel arithmetic unit, accumulator, flag flip-flop and instruction decoder. The 8-bit parallel arithmetic unit has circuitry to perform the four basic arithmetic operations (plus, minus, multiply and divide) as well as logical operations such as AND and OR. The flag flip-flop is used to indicate status such as carry and zero. The accumulator contains one of the operations and the result is usually retained in the accumulator.

XCH A, @Rr	0	0	1	0	0	0	0	r ₀	20	r	1	1	(A) ↔ (M(Rr)) r = 0 ~ 1				Exchanges the contents of memory location, of the current page, whose address is in register Rr, with the contents of register A.	
XCHD A, @Rr	0	0	1	1	0	0	0	r ₀	30	r	1	1	(A ₀ - A ₃) ↔ (M(Rr ₀ - Rr ₃)) r = 0 ~ 1				Exchanges the contents of the low-order four bits of register A with the low-order four bits of memory location, of the current page, whose address is in register Rr.	
Arithmetic	ADD A, #n	0	0	0	0	0	0	1	1	03	n	2	2	(A) ← (A) + n	○	○	1	Adds data n to the contents of register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.
	ADD A, Rr	0	1	1	0	1	r ₂	r ₁	r ₀	6B	r	1	1	(A) ← (A) + (Rr) r = 0 ~ 7	○	○	1	Adds the contents of register Rr to the contents of register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.
	ADD A, @Rr	0	1	1	0	0	0	0	r ₀	B0	r	1	1	(A) ← (A) + (M(Rr)) r = 0 ~ 1	○	○	1	Adds the contents of register A and the contents of memory location, of the current page, whose address is in register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.
	ADDC A, #n	0	0	0	1	0	0	1	1	13	n	2	2	(A) ← (A) + n + (C)	○	○	1	Adds the carry and data n to the contents of register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.
	ADDC A, Rr	0	1	1	1	1	r ₂	r ₁	r ₀	7B	r	1	1	(A) ← (A) + (Rr) + (C) r = 0 ~ 7	○	○	1	Adds the carry and the contents of register Rr to the contents of register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.
	ADDC A, @Rr	0	1	1	1	0	0	0	r ₀	70	r	1	1	(A) ← (A) + (M(Rr)) + (C) r = 0 ~ 1	○	○	1	Adds the carry and the contents of memory location, of the current page, whose address is in register Rr, to the contents of register A and sets the carry flag to 1 if there is an overflow otherwise resets the carry flag to 0. The result is stored in register A.

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

Item Type	Mnemonic	Instruction code			Hexa-decimal	Bytes	Cycles	Function	affected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀						C	AC	None	
Arithmetic	ANL A, #n	0 1 0 1	0 0 1 1	5 3	n	2	2	(A) · (A) ∧ n				The logical product of the contents of register A and data n, is stored in register A.
	ANL A, Rr	0 1 0 1	1 r ₂ r ₁ r ₀	5 B	r	1	1	(A) · (A) ∧ (Rr) r=0-7				The logical product of the contents of register A and the contents of register Rr, is stored in register A.
	ANL A, @Rr	0 1 0 1	0 0 0 r ₀	5 0	+ r	1	1	(A) · (A) ∧ (M(Rr)) r=0-1				The logical product of the contents of register A and the contents of memory location, of the current page, whose address is in register Rr, is stored in register A.
	ORL A, #n	0 1 0 0	0 0 1 1	4 3	n	2	2	(A) ∨ (A) ∨ n				The logical sum of the contents of register A and data n, is stored in register A.
	ORL A, Rr	0 1 0 0	1 r ₂ r ₁ r ₀	4 B	r	1	1	(A) ∨ (A) ∨ (Rr) r=0-7				The logical sum of the contents of register A and the contents of register Rr, is stored in register A.
	ORL A, @Rr	0 1 0 0	0 0 0 r ₀	4 0	+ r	1	1	(A) ∨ (A) ∨ (M(Rr)) r=0-1				The logical sum of the contents of register A and the contents of memory location, of the current page, whose address is in register Rr, is stored in register A.
	XRL A, #n	1 1 0 1	0 0 1 1	0 3	n	2	2	(A) ⊕ (A) ⊕ n				The exclusive OR of the contents of register A and data n, is stored in register A.
	XRL A, Rr	1 1 0 1	1 r ₂ r ₁ r ₀	0 B	+ r	1	1	(A) ⊕ (A) ⊕ (Rr) r=1-7				The exclusive OR of the contents of register A and the contents of register Rr, is stored in register A.
	XRL A, @Rr	1 1 0 1	0 0 0 r ₀	0 0	+ r	1	1	(A) ⊕ (A) ⊕ (M(Rr)) r=0-1				The exclusive OR of the contents of register A and the contents of memory location, of the current page, whose address is in register Rr, is stored in register A.
	INC A	0 0 0 1	0 1 1 1	1 7		1	1	(A) + (A) + 1				Increments the contents of register A by 1. The result is stored in register A, and the carries are unchanged.
	DEC A	0 0 0 0	0 1 1 1	0 7		1	1	(A) - (A) - 1				Decrements the contents of register A by 1. The result is stored in register A, and the carries are unchanged.
	CLR A	0 0 1 0	0 1 1 1	2 7		1	1	(A) → 0				Clears the contents of register A, resets to 0.
	CPL A	0 0 1 1	0 1 1 1	3 7		1	1	(A) · (A̅)				Forms 1's complement of register A, and stores it in register A.
	DA A	0 1 0 1	0 1 1 1	5 7		1	1	(A) → (A) 10 Hexadecimal	⊙	⊙	1	The contents of register A is converted to binary coded decimal notation, and it is stored in register A. If the contents of register A are more than 99 the carry flag is set to 1 otherwise they are reset to 0.
	SWAP A	0 1 0 0	0 1 1 1	4 7		1	1	(A ₄ -A ₇) ↔ (A ₀ -A ₃)				Exchanges the contents of bits 0~3 of register A with the contents of bits 4~7 of register A.
	RL A	1 1 1 0	0 1 1 1	E 7		1	1	(A _{n-1}) → (A _n) (A ₀) → (A ₁) n=0-6				Shifts the contents of register A left one bit. A ₇ the MSB is rotated to A ₀ the LSB.
RLC A	1 1 1 1	0 1 1 1	F 7		1	1	(A _{n-1}) → (A _n) (A ₀) → (C) (C) → (A ₇) n=0-6	⊙			Shifts the contents of register A left one bit. A ₇ the MSB is shifted to the carry flag and the carry flag is shifted to A ₀ the LSB.	
RR A	0 1 1 1	0 1 1 1	7 7		1	1	(A _n) → (A _{n-1}) (A ₇) → (A ₀) n=0-6				Shifts the contents of register A right one bit. A ₀ the LSB is rotated to A ₇ the MSB.	
RRC A	0 1 1 0	0 1 1 1	6 7		1	1	(A ₇) → (A _{n-1}) (A ₀) → (C) (C) → (A ₀) n=0-6	⊙			Shifts the contents of register A right one bit. A ₀ the LSB is shifted to the carry flag and the carry flag is shifted to A ₇ the MSB.	
Register arithmetic	INC Rr	0 0 0 1	1 r ₂ r ₁ r ₀	1 B	r	1	1	(Rr) + (Rr) + 1 r=0-7				Increments the contents of register Rr, by 1. The result is stored in register Rr, and the carries are unchanged.
	INC @Rr	0 0 0 1	0 0 0 r ₀	1 0	+ r	1	1	(M(Rr)) + (M(Rr)) + 1 r=0-1				Increments the contents of the memory location, of the current page, whose address is in register Rr, by 1. Register Rr, uses bit 0-5.
	DEC Rr	1 1 0 0	1 r ₂ r ₁ r ₀	C B	+ r	1	1	(Rr) - (Rr) - 1 r=0-7				Decrements the contents of register Rr, by 1. The result is stored in register Rr, and the carries are unchanged.

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

Item Type	Mnemonic	Instruction code			Hexa-decimal	Bytes	Cycles	Function	Effected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀						C	AC	NOTE	
Jump	JOB m	b ₇ b ₆ b ₅ 1	0 0 1 0	1 2 +	2	2	(A ₆) = 1 then (PC ₃ ~PC ₇) ← m (A ₆) = 0 then (PC) ← (PC) + 2 b ₇ b ₆ b ₅ = 0 ~ 7				Jumps to address m of the current page when bit b of register A is 1. Executes the next instruction when bit b of register A is 0.	
	JTF m	0 0 0 1	0 1 1 0	1 6 m	2	2	(TF) = 1 then (PC ₀ ~PC ₇) ← m (TF) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when the overflow flag of the timer is 1 otherwise the next instruction is executed. Flag is cleared after executing.	
	JMP m	m ₁₀ m ₉ m ₈ 0	0 1 0 0	0 4 +	2	2	(PC ₈ ~PC ₁₀) ← m ₉ ~m ₁₀ (PC ₀ ~PC ₇) ← m ₀ ~m ₇ (PC ₁₁) ← (MBF)				Jumps to address m on page m ₁₀ m ₉ m ₈ in the memory bank indicated by MBF.	
	JMPP @A	1 0 1 1	0 0 1 1	B 3	1	2	(PC ₀ ~PC ₇) ← (M(A))				Jumps to the memory location, of the current page, whose address is in register A. But when the instruction executed was in address 255, jumps to next page	
	DJNZ Rr, m	1 1 1 0	1 r ₂ r ₁ r ₀	E 8 +	2	2	(Rr) ← (Rr) - 1 r = 0 ~ 7 (Rr) = 0 then (PC ₀ ~PC ₇) ← m (Rr) = 0 then (PC) ← (PC) + 2				Decrements the contents of register Rr by 1. Jumps to address m of the current page when the result is not 0, otherwise the next instruction is executed	
	JC m	1 1 1 1	0 1 1 0	F 8 m	2	2	(C) = 1 then (PC ₀ ~PC ₇) ← m (C) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page if the carry flag C is 1, otherwise the next instruction is executed.	
	JNC m	1 1 1 0	0 1 1 0	E 8 m	2	2	(C) = 0 then (PC ₀ ~PC ₇) ← m (C) = 1 then (PC) ← (PC) + 2				Jumps to address m of the current page if the carry flag C is 0, otherwise the next instruction is executed.	
	JZ m	1 1 0 0	0 1 1 0	C 8 m	2	2	(A) = 0 then (PC ₀ ~PC ₇) ← m (A) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when the contents of register A are 0, otherwise the next instruction is executed.	
	JNZ m	1 0 0 1	0 1 1 0	9 8 m	2	2	(A) = 0 then (PC ₀ ~PC ₇) ← m (A) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when the contents of register A are not 0, otherwise the next instruction is executed.	
	JTO m	0 0 1 1	0 1 1 0	3 8 m	?	2	(T ₀) = 1 then (PC ₀ ~PC ₇) ← m (T ₀) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when flag T ₀ is 1 otherwise the next instruction is executed	
	JNTO m	0 0 1 0	0 1 1 0	2 8 m	2	2	(T ₀) = 0 then (PC ₀ ~PC ₇) ← m (T ₀) = 1 then (PC) ← (PC) - 2				Jumps to address m of the current page when flag T ₀ is 0, otherwise the next instruction is executed.	
	JT1 m	0 1 0 1	0 1 1 0	5 8 m	?	2	(T ₁) = 1 then (PC ₀ ~PC ₇) ← m (T ₁) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when flag T ₁ is 1, otherwise the next instruction is executed.	
	JNT1 m	0 1 0 0	0 1 1 0	4 8 m	2	2	(T ₁) = 0 then (PC ₀ ~PC ₇) ← m (T ₁) = 1 then (PC) ← (PC) + 2				Jumps to address m of the current page when flag T ₁ is 0, otherwise the next instruction is executed.	
	JF0 m	1 0 1 1	0 1 1 0	8 8 m	2	2	(F ₀) = 1 then (PC ₀ ~PC ₇) ← m (F ₀) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when flag F ₀ is 1.	
JF1 m	0 1 1 1	0 1 1 0	7 8 m	2	2	(F ₁) = 1 then (PC ₀ ~PC ₇) ← m (F ₁) = 0 then (PC) ← (PC) + 2				Jumps to address m of the current page when flag F ₁ is 1.		
Flag control	CLR C	1 0 0 1	0 1 1 1	9 7	1	1	(C) ← 0	○			Clears the carry flag C, resets it to 0. AC is not affected.	
	CPL C	1 0 1 0	0 1 1 1	A 7	1	1	(C) ← (C̄)	○			Complements the carry flag C. AC is not affected.	
	CLR F ₀	1 0 0 0	0 1 0 1	8 5	1	1	(F ₀) ← 0				Clears the flag F ₀ , resets it to 0.	
	CPL F ₀	1 0 0 1	0 1 0 1	9 5	1	1	(F ₀) ← (F ₀ ̄)				Complements the flag F ₀ .	
	CLR F ₁	1 0 1 0	0 1 0 1	A 5	1	1	(F ₁) ← 0				Clears flag F ₁ , resets it to 0.	
	CPL F ₁	1 0 1 1	0 1 0 1	B 5	1	1	(F ₁) ← (F ₁ ̄)				Complements the flag F ₁ .	

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

Item Type	Mnemonic	Instruction code			Hexa-decimal	Bytes	Cycles	Function	Effected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀						C	AC	Note	
Subroutine call	CALL m	m ₁₀ m ₉ m ₈ 1	0 1 0 0	1 4 + (m ₉ m ₁₀) × 2 m	2	2	((SP)) ← (PC) (PSW ₄ - PSW ₇) (SP) ← (SP) - 1 (PC ₀₋₁₀) ← m (PC ₁₁) ← MBF				Calls subroutine from address m. The program counter and the 4 high-order bits of the PSW are stored in the address indicated by the stack pointer (SP). The SP is incremented by 1 and m is transferred to PC ₀₋₁₀ and the MBF is transferred to PC ₁₁ .	
	RET	1 0 0 0	0 0 1 1	8 3	1	2	(SP) ← (SP) - 1 (PC) ← ((SP))				The SP is decremented by 1. The program counter is restored to the saved setting in the stack indicated by the stack pointer. The PSW is not changed and interrupt disabled is maintained.	
	RETR	1 0 0 1	0 0 1 1	9 3	1	2	(SP) ← ((SP) - 1) (PC) (PSW ₄ - PSW ₇) ← ((SP))				The SP is decremented by 1. The program counter and the 4 high-order bits of the PSW are restored with the saved data in the stack indicated by the stack pointer. The interrupt becomes enabled after the execution is completed.	
Input/Output	IN A, P _p	0 0 0 0	1 0 p ₁ p ₀	0 6 + p	1	2	(A) ← (P _p) p = 1-2				Loads the contents of P _p to register A.	
	OUTL P _p , A	0 0 1 1	1 0 p ₁ p ₀	3 8 + p	1	2	(P _p) ← (A) p = 1-2				Output latches the contents of register A to P _p .	
	ANL P _p , #n	1 0 0 1	1 0 p ₁ p ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	9 8 + p n	2	2	(P _p) ← (P _p) ∧ n p = 1-2				Logical ANDs the contents of P _p and data n. Outputs the result to P _p .	
	ORL P _p , #n	1 0 0 0	1 0 p ₁ p ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	6 8 + p n	2	2	(P _p) ← (P _p) ∨ n p = 1-2				Logical ORs the contents of P _p and data n. Outputs the result to P _p .	
	INS A, BUS	0 0 0 0	1 0 0 0	0 8	1	2	(A) ← (BUS)				Enters the contents of data bus (port 0) to register A.	
	OUTL BUS, A	0 0 0 0	0 0 1 0	0 2	1	2	(BUS) ← (A)				Output latches the contents of register A data to data bus (port 0).	
	ANL BUS, #n	1 0 0 1	1 0 0 0 n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	9 8 n	2	2	(BUS) ← (BUS) ∧ n				Logical ANDs the contents of data bus (port 0) and data n. Outputs the result to data bus (port 0).	
	ORL BUS, #n	1 0 0 0	1 0 0 0 n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	8 8 n	2	2	(BUS) ← (BUS) ∨ n				Logical ORs the contents of data bus (port 0) and data n. Outputs the result to data bus (port 0).	
	MOVD A, P _p	0 0 0 0	1 1 p ₁ p ₀	0 C + p ₁ p ₀	1	2	(A ₀ -A ₃) ← (P _{p0} -P _{p3}) (A ₄ -A ₇) ← 0 p = 4-7				Inputs the contents of P _p to the low order 4 bits of register A and inputs 0 to the high-order 4 bits of register A.	
	MOVD P _p , A	0 0 1 1	1 1 p ₁ p ₀	3 C + p ₁ p ₀	1	2	(P _{p0} -P _{p3}) ← (A ₀ -A ₃) p = 4-7				Outputs the low-order 4 bits of register A to P _p .	
ANLD P _p , A	1 0 0 1	1 1 p ₁ p ₀	9 C + p ₁ p ₀	1	2	(P _{p0} -P _{p3}) ← ((P _{p0} -P _{p3}) ∧ (A ₀ -A ₃)) p = 4-7				Logical ANDs the 4 low-order bits of register A and the contents of P _p . P _p contains the result.		
ORLD P _p , A	1 0 0 0	1 1 p ₁ p ₀	8 C + p ₁ p ₀	1	2	(P _{p0} -P _{p3}) ← ((P _{p0} -P _{p3}) ∨ (A ₀ -A ₃)) p = 4-7				Logical ORs the 4 low-order bits of register A and the contents of P _p . P _p contains the result.

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

Item Type	Mnemonic	Instruction code			Bytes	Cycles	Function	Effected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀	Hexa-decimal				C	AC	Note	
Control	EN I	0 0 0 0	0 1 0 1	0 5	1	1	(INTF) + 1				Enables outside interrupt.
	DIS I	0 0 0 1	0 1 0 1	1 5	1	1	(INTF) - 0				Disables outside interrupt.
	SEL RB ₀	1 1 0 0	0 1 0 1	C 5	1	1	(BS) + 0				Selects working register bank 0.
	SEL RB ₁	1 1 0 1	0 1 0 1	D 5	1	1	(BS) - 1				Selects working register bank 1.
	SEL MB ₀	1 1 1 0	0 1 0 1	E 5	1	1	(MBF) + 0				Selects memory bank 0.
	SEL MB ₁	1 1 1 1	0 1 0 1	F 5	1	1	(MBF) - 1				Selects memory bank 1.
	ENTO CLK	0 1 1 1	0 1 0 1	7 5	1	1					Enables output of clock signal from terminal T _e .
Timer/event counter control	MOV A, T	0 1 0 0	0 0 1 0	4 2	1	1	(A) + (T)				Transfers the contents of timer/event counter to register A.
	MOV T, A	0 1 1 0	0 0 1 0	6 2	1	1	(T) + (A)				Transfers the contents of register A to timer/event counter.
	STRT T	0 1 0 1	0 1 0 1	5 6	1	1					Starts timer operation of timer/event counter. Minimum count cycle is 80µs.
	STRT CNT	0 1 0 0	0 1 0 1	4 5	1	1					Starts operation as event counter of timer/event counter. Counts up when terminated T _i changes to input high-level for input low-level. Minimum count cycle is 7.5µs.
	STOP TCNT	0 1 1 0	0 1 0 1	8 5	1	1					Stops operation of timer or event counter.
	EN TCNTI	0 0 1 0	0 1 0 1	2 5	1	1	(TCNTF) + 1				Enables interrupt of timer/event counter.
	DIS TCNTI	0 0 1 1	0 1 0 1	3 5	1	1	(TCNTF) - 0				Disables interrupt of timer/event counter. Resets interrupt flip-flop of CPU which is set during the CPU stand-by. Timer overflow flag isn't affected.
Misc.	NOP	0 0 0 0	0 0 0 0	0 0	1	1					No operation. Execution time is 1 cycle.

Note 1: Executing an instruction may produce a carry (overflow or underflow). The carry may be disregarded (lost) or it may be transferred to C/AC (saved). The saving of a carry is not shown in the function equations, but is instead shown in the carry columns C and AC. The detail attention of carries for instructions ADD, ADDC and DA is as follows.

- (C) + 1 at overflow of the accumulator is produced.
- (C) + 0 at no overflow of the accumulator is produced.
- (AC) + 1 at overflow of the bit 3 of the accumulator.
- (AC) + 0 at no overflow.

2: The contents of ST₆ ~ ST₇ is read when the host computer reads the status of M5L8041A-XXXX.

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

FUNCTION OF MELPS 8-48 MICROCOMPUTERS

Symbol	Meaning	Symbol	Meaning
A	8-bit register (accumulator)	PC	Program counter
A₀~A₃	The low-order 4 bits of the register A	PC₀~PC₇	The low order 8 bits of the program counter
A₄~A₇	The high-order 4 bits of the register A	PC₈~PC₁₀	The high-order 3 bits of the program counter
A₀~A_n, A_{n+1}	The bits of the register A	PSW	Program status word
b	The value of the bits 6~7 of the first byte machine code	Rr	Register designator
b₇b₆b₅	The bits 5~7 of the first byte machine code	r	Register number
BS	Register bank select	r₀	The value of bit 0 of the machine code
BUS	Corresponds to the port 0 (bus I/O port)	r₂r₁r₀	The value of bits 0~2 of the machine code
AC	Auxiliary carry flag	S₂S₁S₀	The value of bits 0~2 of the stack pointer
C	Carry flag	SP	Stack pointer
OBB	Data bus buffer	ST₄~ST₇	Bits 4~7 of the status register
F₀	Flag 0	STS	System status
F₁	Flag 1	T	Timer/event counter
INTF	Interrupt flag	T₀	Test: pin 0
IBF	Input buffer full flag	T₁	Test: pin 1
m	The value of the 11-bit address	TCNTF	Timer/event counter overflow interrupt flag
m₇m₆m₅m₄m₃m₂m₁m₀	The second byte (low-order 8 bits) machine code of the 11-bit address	TF	Timer flag
m₁₀m₉ m₈	The bits 5~7 of the first byte (high-order 3 bits) machine code of the 11-bit address	#	Symbol to indicate the immediate data
(M (A))	The content of the memory location addressed by the register A	@	Symbol to indicate the content of the memory location address by the register
(M (Rr))	The content of the memory location addressed by the register Rr	←	Shows direction of data flow
(Mx (Rr))	The content of the external memory location addressed by the register Rr	↔	Exchanges the contents of data
MBF	Memory bank flag	()	Contents of register, memory location or flag
n	The value of the immediate data	Λ	Logical AND
n₇n₆n₅n₄n₃n₂n₁n₀	The immediate data of the second byte machine code	V	Inclusive OR
OBF	Output buffer full flag	∨	Exclusive OR
p	Port number	—	Negation
Pp	Port designator	○	Content of flag is set or reset after execution
p₁p₀	The bits of the machine code corresponding to the port number

MITSUBISHI MICROCOMPUTERS MELPS 8-48 MICROCOMPUTERS

DEVELOPMENT OF MASK-PROGRAMMABLE ROMs

GENERAL INFORMATION

This information explains how to specify the object program for the automatic design system for mask ROMs. This system for mask ROM production has been developed to accept a customer's object program specifications for the automatic design system for a mask ROM.

The main segments of the automatic design system are:

1. The plotter instructions for mask production.
2. A check list for verifying that the customer's specifications have been met.
3. A test program to assure that the production ROMs meet specifications.

An EPROM in which a program is stored is used for a customer's specifications. A separate (set of) EPROM(s) should be produced for each object program.

Three sets of EPROM(s) should be supplied with the confirmation material.

3. All the data stored in the EPROM are considered as valid and processed to make masks.

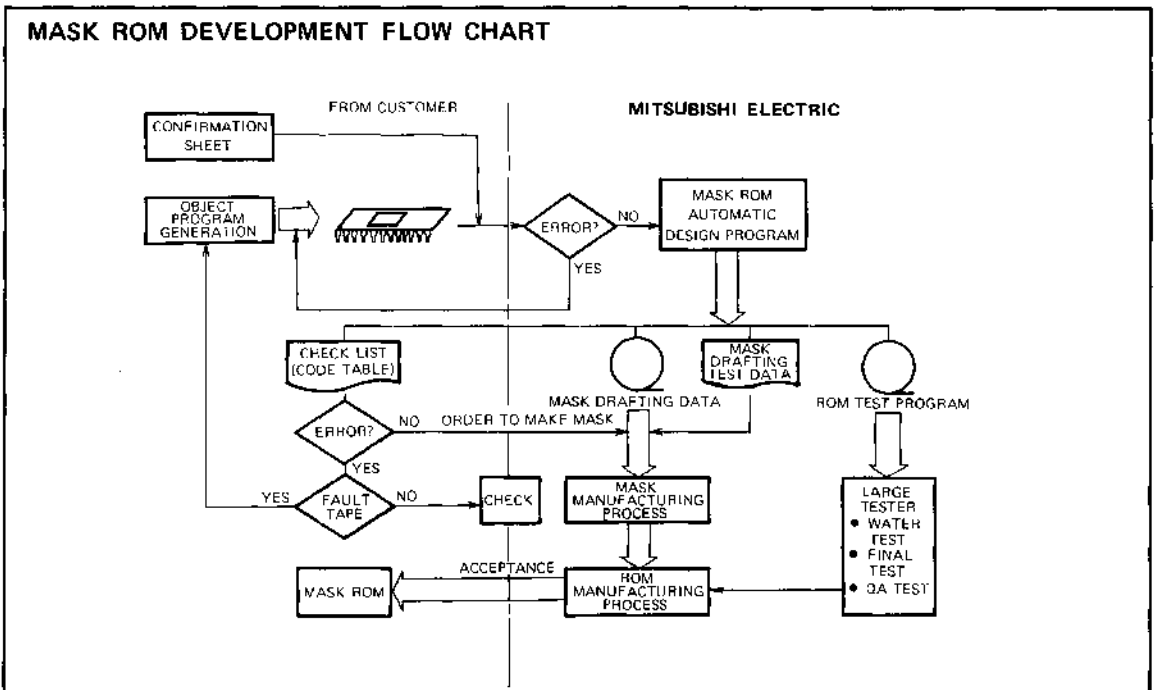

ITEMS TO CONFIRM FOR ORDERING

1. Specify the type number M5L8048-XXXX or M5L8049-XXXX. The 3-digit number XXX will be assigned by Mitsubishi.
2. Clearly indicate the type number of EPROM and address designation letter symbols A and B on the supplied EPROMs.

EPROM SPECIFICATIONS

1. The Mitsubishi M5L2708K, M5L2716K, M5L2732K or M5L8748S are standard, but Intel 2708, 2716, 2732, 8748 or equivalent devices may be used.
2. The high-level data of both data outputs and address inputs of the supplied EPROM will be programmed as '1', and low-level as '0'.

Customer	Signature
Company name _____	Prepared
Company address _____ Tel _____	Approved
Company contact _____ Date _____	

The single-chip microcomputer type number to order and the type of EPROMs to be supplied should be specified by checking in the boxes. Three sets of EPROMs should be supplied.

Single-chip microcomputer type number \ EPROM type number	2708	2716	2732	8748
<input type="checkbox"/> M5L8048-XXXP	<input type="checkbox"/> A(000 ₁₆ ~3FF ₁₆)	<input type="checkbox"/> A(000 ₁₆ ~3FF ₁₆)	<input type="checkbox"/> A(000 ₁₆ ~3FF ₁₆)	<input type="checkbox"/> A(000 ₁₆ ~3FF ₁₆)
<input type="checkbox"/> M5L8049-XXXP	<input type="checkbox"/> A(000 ₁₆ ~3FF ₁₆) <input type="checkbox"/> B(400 ₁₆ ~7FF ₁₆)	<input type="checkbox"/> A(000 ₁₆ ~7FF ₁₆)	<input type="checkbox"/> A(000 ₁₆ ~7FF ₁₆)	—

- Note 1 The high-level data of both data outputs and address inputs of the supplied EPROM will be programmed as '1', and low-level as '0'.
 2 Clearly indicate the type number of EPROMs and address designation letter symbols A and B on the supplied EPROMs.
 3 The data of the addresses in parentheses on the EPROM are programmed onto the ROM.
 4 The data from each PROM in the set is compared and if 2 of the 3 are equal, the equal value will be programmed into the ROM. When the 3 values are different, programming is halted and the customer is notified of the error. The error report will show the address and data.

CUSTOMER'S IDENTIFICATION MARK

If you require a special identification mark, please specify in the following format.

Mitsubishi IC type number												

- Note 5 A mark field should start with the box at the extreme right.
 6 The identification mark should be no more than 12 characters consisting of alphanumeric characters (except J.I. and OI or dashes).

COMMENTS

MITSUBISHI MICROCOMPUTERS M5L8048-XXXP, M5L8035LP

SINGLE-CHIP 8-BIT MICROCOMPUTER

DESCRIPTION

The M5L8048-XXXP and M5L8035LP are 8-bit parallel microcomputer fabricated on a single chip using high-speed N-channel silicon-gate ED-MOS technology.

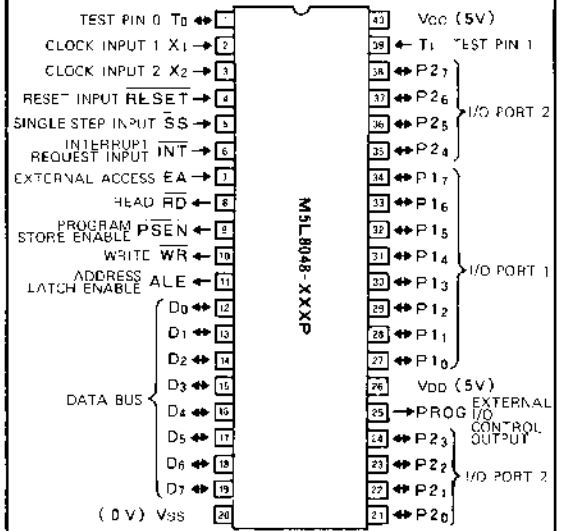

FEATURES

- Single 5V power supply
- Instruction cycle 2.5 μ s (min)
- Basic machine instructions: 96
 - 1-byte instructions: 68
 - 2-byte instructions: 28
- Direct addressing up to 4096 bytes
- Internal ROM 1024 bytes (for M5L8048-XXXP only)
- Internal RAM 64 bytes
- Built-in timer/event counter 8 bits
- I/O Ports 27 lines
- Easily expandable Memory and I/O
- Subroutine nesting 8 levels
- External and timer/event counter interrupt . 1 level each
- Low power standby mode
- External RAM 256 bytes
- Interchangeable with Intel's P8048 and P8035L in pin configuration and electrical characteristics

APPLICATION

- Control processor or CPU for a wide variety of applications

PIN CONFIGURATION (TOP VIEW)

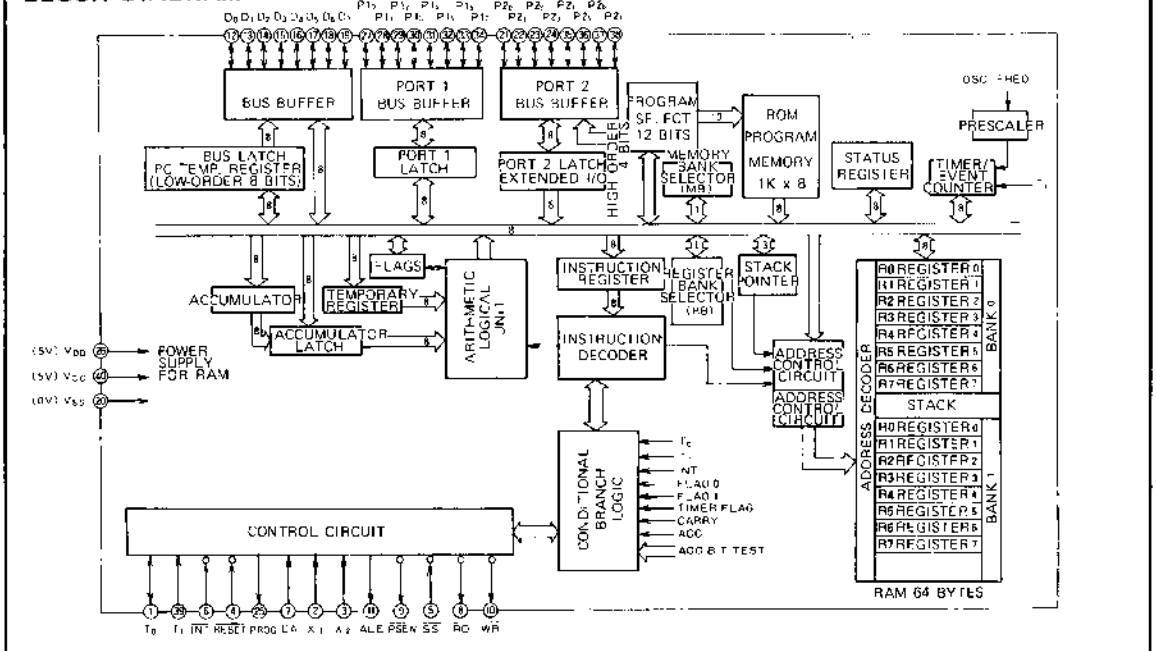

Outline 40P1

FUNCTION

The M5L8048-XXXP and M5L8035LP are integrated 8-bit CPU, with memory (ROM, RAM) and timer/event counter interrupt all contained on a single chip.

PIN DESCRIPTION

Pin	Name	Input or Output	Function
VSS	Ground		Normally connected to ground (0V).
VCC	Main power supply		Connected to 5V power supply.
VDD	Power supply		① Connected to 5V power supply. ② Used for memory hold when VCC is cut.
PROG	Program	Output	Strobe signal for M5L8243P I/O Expander.
P1 ₀ ~P1 ₇	Port 1	Input/output	Quasi bidirectional port. When used as an input port, FF ₁₆ must first be output to this port. After reset, when not used as an output port nothing can be output.
P2 ₀ ~P2 ₇	Port 2	Input/output	① The same as port 1.
		Output	② P2 ₀ ~P2 ₃ output the high-order 4 bits of the program counter when using external program memory.
		Input/output	③ P2 ₀ ~P2 ₃ serve as a 4-bit I/O expander bus for the M5L8243P.
D ₀ ~D ₇	Data bus	Input/output	① Provides true bidirectional bus transfer of instructions and data between the CPU and external memory. Synchronizing is done with signals $\overline{RD}/\overline{WR}$. The output data is latched.
			② When using external program memory the output of the low-order 8 bits of the program counter are synchronized with ALE. After that the transfer of the instruction code or data from external program memory is synchronized with \overline{PSEN} .
			③ The output of addresses for data using external data memory is synchronized with ALE. After that the transfer of data with the external data memory is synchronized with $\overline{RD}/\overline{WR}$. (MOVX A, @Rr and MOVX @Rr, A)
T ₀	Test pin 0	Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JTD m and JNTD m)
		Output	② Used for outputting the internal clock signal. (FINT0 CLK)
T ₁	Test pin 1	Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JT1 m and JNT1 m)
			② When enabled event signals are transferred to the timer/event counter. (START CNT)
\overline{INT}	Interrupt	Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JIN1 m) ② Used for external interrupt to CPU.
\overline{RD}	Read control	Output	Read control signal used when the CPU requests data from external data memory or external devices to be transferred to the data bus. (MOVX A, @Rr and INS A, BUS)
\overline{WR}	Write control	Output	Write control signal used when the CPU sends data through the data bus to external data memory or external device. (MOVX @Rr, A and OUTL BUS, A)
\overline{RESET}	Reset	Input	Control used to initialize the CPU.
ALE	Address latch enable	Output	A signal used for latching the address on the data bus. An ALE signal occurs once during each cycle.
\overline{PSEN}	Program store enable	Output	Strobe signal to fetch external program memory.
\overline{SS}	Single step	Input	Control signal used in conjunction with ALE to stop the CPU through each instruction, in the single step mode.
EA	External access	Input	① Normally maintained at 0V. ② When the level is raised to 5V, external memory will be accessed even when the address is less than 400 _h (1024). The M5L8035LP is raised to 5V.
X ₁ , X ₂	Crystal inputs	Input	External crystal oscillator or RC circuit input for generating internal clock signals. An external clock signal can be input through X ₁ or X ₂ .

MITSUBISHI MICROCOMPUTERS MSL8748S

SINGLE-CHIP 8-BIT MICROCOMPUTER WITH EPROM

DESCRIPTION

The M5L8748S is an 8-bit parallel microcomputer fabricated on a single-chip using high-speed N-channel silicon-gate ED-MOS technology. This contains ultraviolet-light erasable and electrically reprogrammable ROM (EPROM) on a chip, so it is easy to change the program stored in the EPROM.

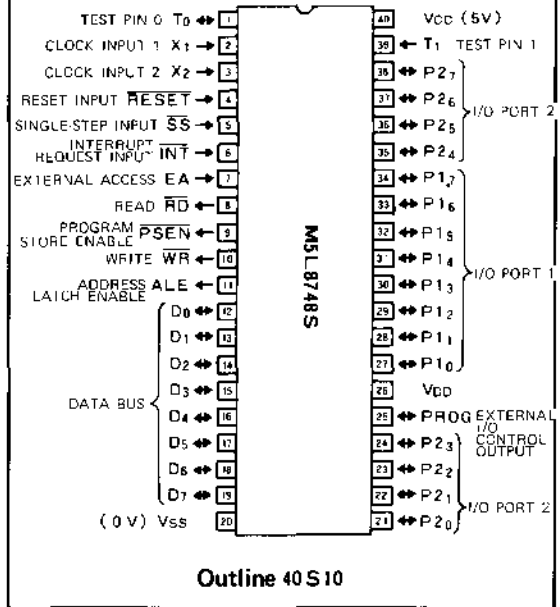

FEATURES

- Single 5V power supply
- Instruction cycle 2.5μs (min)
- Basic machine instructions 96
 - 1-byte instructions: 68
 - 2-byte instructions: 28
- Direct addressing up to 4096 bytes
- Internal EPROM 1024 bytes
- Internal RAM 64 bytes
- Built-in timer/event counter 8 bits
- I/O Ports 27 lines
- Easily expandable memory and I/O
- Subroutine nesting 8 levels
- External and timer/event counter interrupt . 1 level each
- External RAM 256 bytes
- Interchangeable with the Intel's D8748 in pin configuration and electrical characteristics

APPLICATIONS

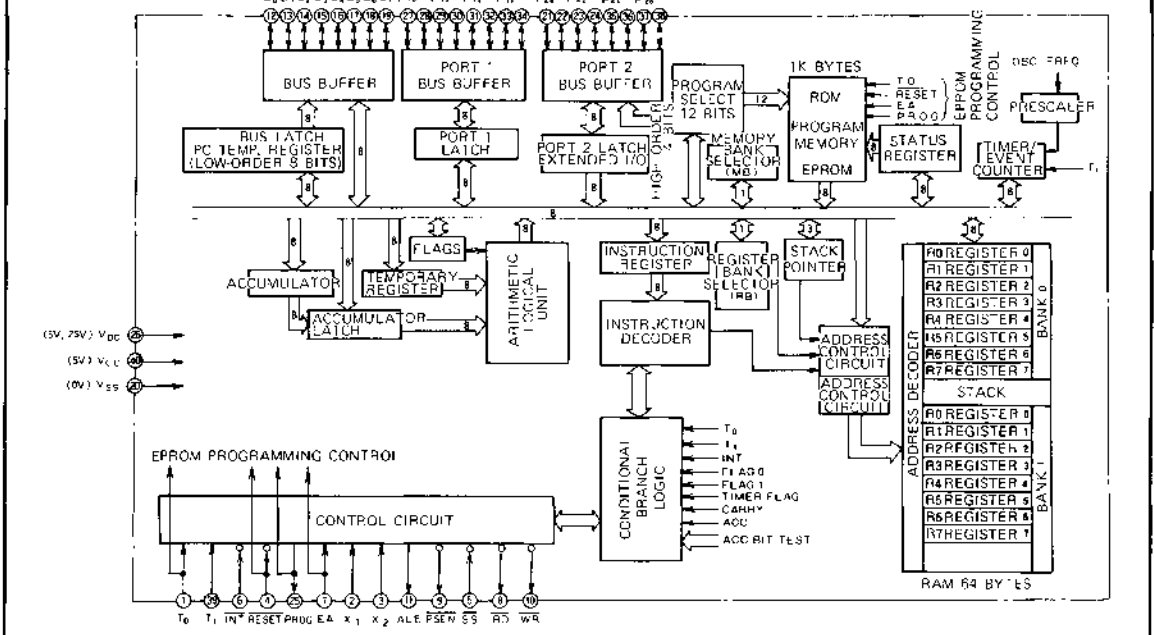

- A CPU for special repetitive processing or control for which a small number of units are to be produced.

PIN CONFIGURATION (TOP VIEW)

- A debugging CPU for program, application and system design development
- A CPU for prototype and preproduction systems prior to factory-programmed mask ROM production

BLOCK DIAGRAM

SINGLE-CHIP 8-BIT MICROCOMPUTER WITH EPROM

PIN DESCRIPTION

Pin	Name	Input or Output	Function
VSS	Ground		Normally connected to ground (0V).
VCC	Main power supply		Connected to 5V power supply.
VDD	Program power supply		① Normally connected to 5V power supply. ② When programming to EPROM, 25V is required.
PROG	Program	Input	① Used to supply 25V program pulses (50 ms width) from an outside source when programming to EPROM.
		Output	② Strobe signal for M5L8243P I/O Expander.
P1 ₀ ~P1 ₇	Port 1	Input/output	Quasi-bidirectional port. When used as an input port, FF ₁₆ must first be output to this port. After reset, when not used as an output port nothing can be output.
P2 ₀ ~P2 ₃	Port 2	Input/output	① The same as port 1.
		Output	② P2 ₀ ~P2 ₃ output the high-order 4 bits of the program counter when using external program memory.
		Input/output	③ P2 ₀ ~P2 ₃ serve as a 4-bit I/O expander bus for the M5L8243P.
		Input/output	① Provides true bidirectional bus transfer of instructions and data between the CPU and external memory. Synchronizing is done with signals RD/WB. The output data is latched. ② When using external program memory the output of the low-order 8 bits of the program counter are synchronized with ALE. After that the transfer of the instruction code or data from external program memory is synchronized with PSEN. ③ The output of addresses for data using external data memory is synchronized with ALE. After that the transfer of data with the external data memory is synchronized with RD/WB. (MOVX @Rr and MOVX @Rr, A)
D ₀ - D ₇	Data bus	Input/output	
		Input/output	
T ₀	Test pin 0	Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JTO m and JNT0 m)
		Output	② Used for outputting the internal clock signal. (ENT0 CLK)
T ₁	Test pin 1	Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JTI m and JNT1 m) ② When enabled event signals are transferred to the timer/event counter. (STRT CNT)
		Input	① Control signal from an external source for conditional jumping in a program. Jumping is dependent on external conditions. (JN1 m) ② Used for external interrupt to CPU.
INT	Interrupt	Input	
RD	Read control	Output	Read control signal used when the CPU requests data from external data memory or external devices to be transferred to the data bus. (MOVX @Rr and INS A, BUS)
WR	Write control	Output	Write control signal used when the CPU sends data through the data bus to external data memory or external devices. (MOVX @Rr, A and OUTL BUS, A)
RESET	Reset	Input/output	① Control used to initialize the CPU. ② Latch signal for the EPROM address when programming to EPROM and for reading from EPROM (verify mode).
ALE	Address latch enable	Output	A signal used for latching the address on the data bus. An ALE signal occurs once during each cycle.
PSEN	Program store enable	Output	Strobe signal used to fetch from external program memory.
SS	Single step	Input	Control signal used in conjunction with ALE to stop program execution at the finish of each instruction, in the single step mode.
EA	External access	Input	① Normally maintained at 0V. ② When the level is raised to 5V, external memory will be accessed even when the address is less than 400 ₁₆ (1024). ③ When in the programming mode for the EPROM a 25V power supply must be available at this terminal.
X ₁ , X ₂	Crystal inputs	Input	External crystal oscillator or RC circuit input for generating internal clock signals. An external clock signal can be input through X ₁ or X ₂ .

PROGRAMMING to EPROM

SINGLE-CHIP 8-BIT MICROCOMPUTER WITH EPROM

PROGRAMMING TO EPROM AND ERASING

Details of how to program data onto the EPROM for the M5L8748S is shown in Fig. 1. The EPROM can be erased by approximately 15 Ws/cm² of exposure to high-intensity 2537Å short-wave ultraviolet rays.

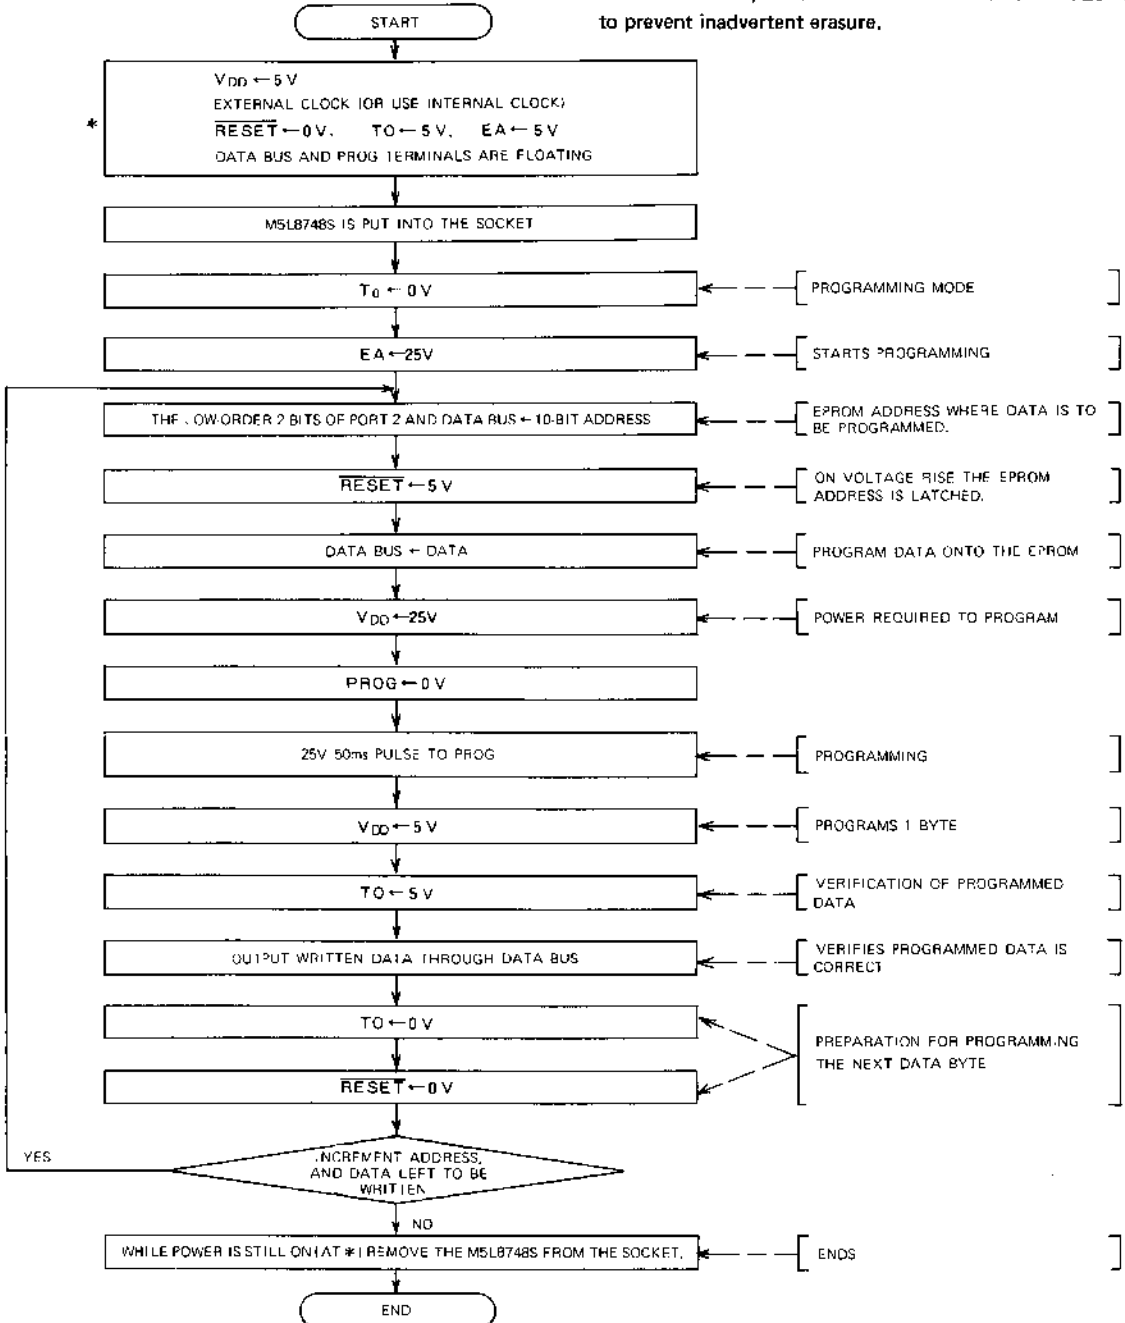

For example: the S-52 ultraviolet lamp has an intensity of 17,000μW/cm² at a distance of 2.4 cm from the lamp.

The necessary exposure would be:

$$\frac{15\text{Ws/cm}^2}{17,000\mu\text{W/cm}^2} = 900 \text{ seconds} = 15 \text{ minutes}$$

Once data has been entered on the EPROM an opaque label should be pasted over the window of the M5L8748S to prevent inadvertent erasure.

Fig. 1 Flowchart of programming onto the EPROM

INPUT/OUTPUT EXPANDER

DESCRIPTION

The M5L8243P is an input/output expander fabricated using N-channel silicon-gate ED-MOS technology. This device is designed specifically to provide a low-cost means of I/O expansion for the MELPS 8-48 single-chip micro-computer and M5L8041A-XXXP.

FEATURES

- 16 Input/output pins ($I_{OL} = 5.0\text{mA}(\text{max})$)
- Simple interface to MELPS 8-48 microcomputers
- Single 5V power supply
- Low power dissipation: 50mW (typ)
- Interchangeable with Intel's 8243 in pin configuration and electrical characteristics

APPLICATION

- I/O expansion for the MELPS 8-48 single-chip micro-computers.

FUNCTION

The M5L8243P is designed to provide a low-cost means of I/O expansion for the M5L8041A-XXXP universal peripheral interface and the M5L8048 and M5L8049 single-chip microcomputers. The M5L8243P consists of four 4-bit bidirectional static I/O ports and one 4-bit port which serves as an interface to the M5L8041A-XXXP and M5L8048/9. Thus multiple M5L8243Ps can be added to a single master.

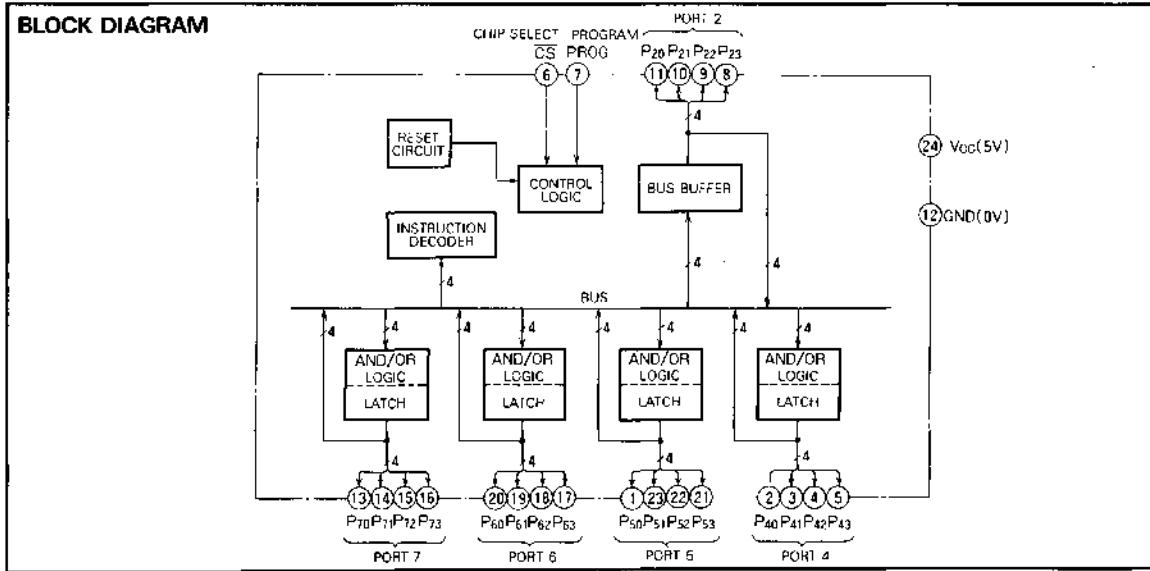

Using the original instruction set of the master, the M5L8243P serves as the in resident I/O facility. Its I/O ports are accessed by instructions MOV, ANL and ORL.

PIN CONFIGURATION (TOP VIEW)

Outline 24P1

6

INPUT/OUTPUT EXPANDER

PIN DESCRIPTION

Symbol	Name	Input or output	Function
PROG	Program	In	A high-to-low transition on PROG signifies that address (PORT 4-7) and control are available on PORT 2, and a low-to-high transition signifies that the designated data is available on the designated port through PORT 2. The designation is shown in Table 1.
\overline{CS}	Chip select	In	Chip select input. A high on \overline{CS} causes PROG input to be regarded high inside the M5L8243P, then this inhibits any change of output or internal status.
P ₂₀ ~P ₂₃	Input/output port 2	In/out	The 4-bit bidirectional port contains the address and control bits shown in Table 1 on a high-to-low transition of PROG. During a low-to-high transition it contains the input (output) data on this port.
P ₄₀ ~P ₄₃ P ₅₀ ~P ₅₃ P ₆₀ ~P ₆₃ P ₇₀ ~P ₇₃	Input/output port 4 Input/output port 5 Input/output port 6 Input/output port 7	In/out	The 4-bit bidirectional I/O port. May be programmed to be input, low-impedance latched output or a three-state. This port is automatically set output mode when it is written, ANLed or ORLed, then continues its mode until next read operation. After reset on a read operation, this port is in high-impedance and input mode.

OPERATION

The M5L8243P is an input/output expander designed specifically for the M5L8014A-XXXP and MELPS 8-48 single-chip 8-bit microcomputer. The M5L8014A-XXXP and MELPS 8-48 already have instructions and PROG pin to communicate with the M5L8243P.

An example of the M5L8243P and the M5L8014A-XXXP is shown in Fig. 1. The following description of the M5L8243P basic operation is made according to Fig. 1.

Upon initial application of power supply to the device, and then about 50ms after, resident bias circuits become stable and each device is ready to operate. And each port of the M5L8243P is set input mode (high-impedance) by means of a resident power-on initialization circuit.

When the microcomputer begins to execute a transfer instruction

```
MOV D A, Pi    i = 4, 5, 6, 7
```

which means the value on the port Pi is transferred to the accumulator, then the signals are sent out on the pins PROG and P₂₀~P₂₃ as shown in Timing Diagram.

On the high-to-low transition of the pin PROG, the M5L8243P latches the instructions (ex. 0000) into itself from pins P₂₀~P₂₃ and transfers them to the instruction register (① in Timing Diagram). During the low-level of PROG, the M5L8243P continuously outputs the contents of the specified input (output) port (in this case port P₄) to pins P₂₀~P₂₃ (② in Timing Diagram). The microcomputer, at an appropriate time, latches the level of pins P₂₀~P₂₃ and resumes high-level of PROG.

The next example is the case in which the microcomputer executes

```
MOV D Pi, A    i = 4, 5, 6, 7
```

the transfer (output) instruction.

In this case, as in the previous case, on the high-to-low transition of the pin PROG, the M5L8243P latches

the instructions (ex. 0110) into itself from pins P₂₀~P₂₃ and transfers them to the instruction register (① in Timing Diagram).

After this, the microcomputer sends out high to the pin PROG, transferring the data to pins P₂₀~P₂₃ which is an output data to input/output port. Then the M5L8243P transfers the data of pins P₂₀~P₂₃ to the port latch of the designated input/output port (in this case P₆). In a few seconds after a low-to-high transition on the PROG, the designated port (P₆) becomes in an output mode and the data of the port latch are transferred to the port pins (③ in Timing Diagram).

When instructions

```
ANLD Pi, A
ORLD Pi, A    i = 4, 5, 6, 7
```

are executed, the microcomputer generally operates as same function as MOV D Pi, A.

It only differs in that the data of port latch after ④ in the Timing Diagram is ANDed or ORed with the data of port latch before ④ and the data of pins P₂₀~P₂₃.

When instructions

```
MOV D Pi, A
ANLD Pi, A
ORLD Pi, A    i = 4, 5, 6, 7
```

are executed toward the port in an output mode, the outputs are generated on the port as soon as low-to-high transition on the PROG occurs.

When the mode of the output port is going to be changed during the execution and the instruction

```
MOV D A, Pi    i = 4, 5, 6, 7
```

is executed, it is preferable to execute one dummy instruction. Because it takes a little time to turn the designated port into a high-impedance state after high-to-low transition on the PROG, the result may be that the first instruction is not read correctly.

Current Sinking Capability

Each of the 16 I/O lines of the M5L8243P is capable of sinking 5mA simultaneously ($V_{OL} = 0.45V$ max). However, the drive capacity of each line depends upon whether all lines are sinking current simultaneously and on the degree of loading. This is illustrated in the curve shown.

Example

Assuming that the remaining pins are not loaded, how many pins would be able to accommodate 5TTL loads (1.6mA)?

$$I_{OL} = 1.6mA \times 5 = 8mA \text{ (sink current for each pin)}$$

$$\Sigma I_{OL} = 60mA \text{ from curve (curve A)}$$

(total sinking current)

$$\text{Number of pins} = 60mA \div 8mA/\text{pin} = 7.5 = 7 \text{ lines}$$

For this case, each of the 7 lines could sink 8mA for a total of 56mA. Since 4mA reserve sinking capability exists, 9 of the I/O lines of the M5L8243P can be divided arbitrarily.

INPUT/OUTPUT EXPANDER

Example

To use 20mA sinking capability at port 7, find the effects on the sinking capabilities of the other I/O lines.

Assume the M5L8243P is driving loads as shown below.

2 lines: -20mA ($V_{OL} = 1.0V$ max, port 7 only)

8 lines: -4mA ($V_{OL} = 0.45V$ max)

6 lines: -3.2mA ($V_{OL} = 0.5V$ max)

Is this within the allowable limit?

$$\Sigma I_{OL} = (20mA \times 2) + (4mA \times 8) + (3.2mA \times 6) = 91.2mA$$

From the curve we see that with respect to $I_{OL} = 4mA$, I_{OL} is 93mA (curve B) and that the above load of 91.2mA is within the limit of 93mA.

Note: The sinking current of ports 4 ~ 7 must not exceed 30mA regardless of the value of V_{OL} .

Fig. 2 Expansion interface example

MELPS 8/85 MICROPROCESSORS

8-BIT PARALLEL MICROPROCESSOR

DESCRIPTION

This is a family of single-chip 8-bit parallel central processing units (CPUs) developed using the N-channel silicon-gate ED-MOS process. It requires a single 5V power supply and has a basic clock rate of 3MHz. With an instruction set that is completely compatible with that of the M5L8080AP,S, this device is designed to improve on the M5L 8080A with higher system speed.

FEATURES

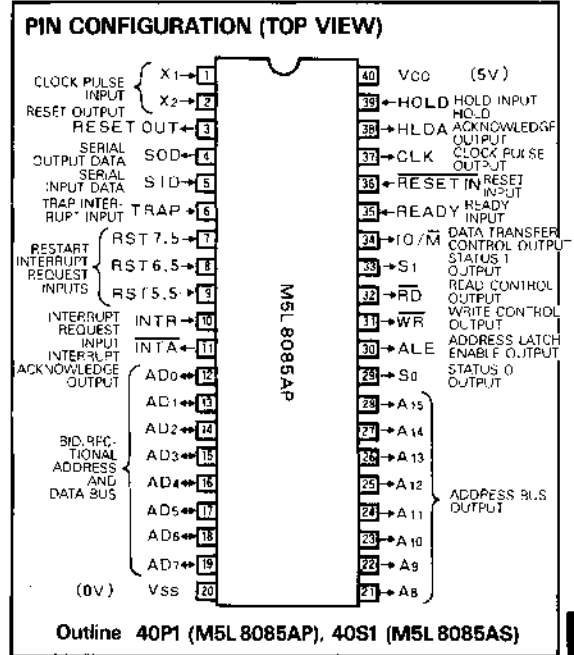

- Single 5V power supply
- Software compatibility with the M5L8080AP,S (with two additional instructions)
- Instruction cycle 1.3 μ s (min.)
- Clock generator (with an external crystal or RC circuit)
- Built-in system controller
- Four vectored interrupts (one of which is non-maskable)
- Serial I/O port: 1 each
- Decimal, binary, and double precision arithmetic operations
- Direct addressing up to 64K bytes of memory
- Interchangeable with Intel's 8085A in pin connection and electrical characteristics

APPLICATION

- Central processing unit for a microcomputer

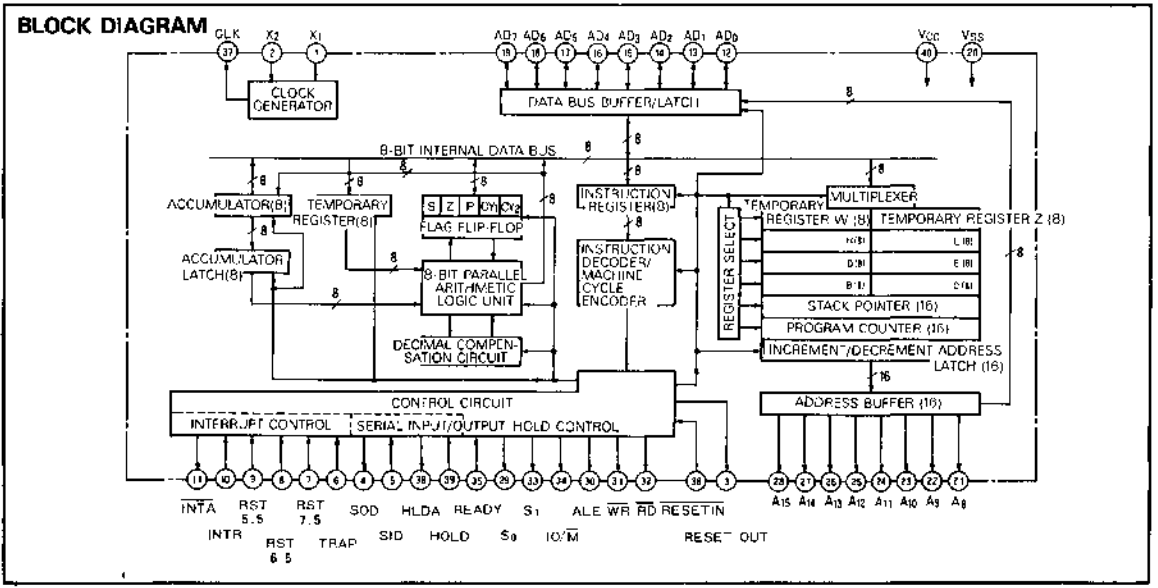

FUNCTION

Under the multiplexed data bus concept adopted, the high-order 8 bits of the address are used only as an address bus and the low-order 8 bits are used as an address/data bus. During the first clock cycle of an instruction cycle, the address is transferred. The low-order 8 bits of the address are stored in the external latch by the address latch enable (ALE) signal. During the second and third clock cycles, the address/data bus functions

7

as the data bus, transferring the data to memory or to the I/O. For bus control, the device provides \overline{RD} , \overline{WR} , and $\overline{IO/M}$ signals and an interrupt acknowledge signal \overline{INTA} . The \overline{HOLD} , \overline{READY} and all interrupt signals are synchronized with the clock pulse. For simple serial data transfer it provides both a serial input data (SID) line and a serial output data (SOD) line. It also has three maskable restart interrupts and one non-maskable trap interrupt.

8-BIT PARALLEL MICROPROCESSOR

PIN DESCRIPTIONS

Pin	Name	Input or output	Functions															
A ₈ ~ A ₁₅	Address bus	Out	Outputs the high-order 8 bits of the memory address or the 8 bits of the I/O address. It remains in the high-impedance state during the HOLD and HALT modes.															
AD ₀ ~ AD ₇	Bidirectional address and data bus	In/out	The low-order I/O address appears during the first clock cycle. During the second and third clock cycles, it becomes the data bus. It remains in the high-impedance state during the HOLD and HALT modes.															
ALE	Address latch enable	Out	This signal is generated during the first clock cycle, to enable the address to be latched into the latches of peripherals. The falling edge of ALE is guaranteed to latch the address information. The ALE can also be used to strobe the status information, but it is kept in the low-level state during bus idle machine cycles.															
S ₀ , S ₁	Status	Out	Indicates the status of the bus. <table style="margin-left: 40px;"> <tr> <td></td> <td>S₁</td> <td>S₀</td> </tr> <tr> <td>HALT</td> <td>0</td> <td>0</td> </tr> <tr> <td>WRITE</td> <td>0</td> <td>1</td> </tr> <tr> <td>READ</td> <td>1</td> <td>0</td> </tr> <tr> <td>FETCH</td> <td>1</td> <td>1</td> </tr> </table> <p>The S₁ signal can be used as an advanced R/W status.</p>		S ₁	S ₀	HALT	0	0	WRITE	0	1	READ	1	0	FETCH	1	1
	S ₁	S ₀																
HALT	0	0																
WRITE	0	1																
READ	1	0																
FETCH	1	1																
\overline{RD}	Read control	Out	Indicates that the selected memory or I/O address is to be read and that the data bus is active for data transfer. It remains in the high-impedance state during the HOLD and HALT modes.															
\overline{WR}	Write control	Out	Indicates that the data on the data bus is to be written into the selected memory at the trailing edge of the signal \overline{WR} . It remains in the high-impedance state during the HOLD and HALT modes.															
RST5.5 RST6.5 RST7.5	Restart interrupt request	In	Input timing is the same as for INTR for these three signals. They all cause an automatic insertion of an internal RESTART. RST 7.5 has the highest priority while RST 5.5 has the lowest. All three signals have a higher priority than INTR.															
TRAP	Trap interrupt	In	A non-maskable restart interrupt which is recognized at the same time as an INTR. It is not affected by any mask or another interrupt. It has the highest interrupt priority.															
\overline{RESET} IN	Reset input	In	This signal (at least three clock cycles are necessary) sets the program counter to zero and resets the interrupt enable and HLDA flip-flops. None of the other flags or registers (except the instruction register) are affected. The CPU is held in the reset mode as long as the signal is applied.															
RESET OUT	Reset output	Out	This signal indicates that the CPU is in the reset mode. It can be used as a system RESET. The signal is synchronized to the processor clock.															
X ₁ , X ₂	Clock input	In	These pins are used to connect an external crystal or CR circuit to the internal clock generator. An external clock pulse can also be input through X ₁ .															
CLK	Clock output	Out	Clock pulses are available from this pin when a crystal or CR circuit is used as an input to the CPU.															
IO/ \overline{M}	Data transfer control output	Out	This signal indicates whether the read/write is to memory or to I/Os. It remains in the high-impedance state during the HOLD and HALT modes.															
READY	Ready input	In	When it is at high level during a read or write cycle the READY indicates that the memory or peripheral is ready to send or receive data. When the signal is at low-level, the CPU will wait for the signal to turn high-level before completing the read or write cycle.															
HOLD	Hold request signal	In	When the CPU receives a HOLD request, it relinquishes the use of the buses as soon as the current machine cycle is completed. The CPU can regain the use of buses only after the HOLD state is removed. Upon acknowledging the HOLD signal, the address bus, the data bus, \overline{RD} , \overline{WR} and IO/ \overline{M} lines are put in the high-impedance state.															
HLDA	Hold acknowledge signal	Out	By this signal the processor acknowledges the HOLD request signal and indicates that it will relinquish the buses in the next clock cycle. The signal is returned to the low-level state after the HOLD request is completed. The processor resumes the use of the buses one half clock cycle after the signal HLDA goes low.															
INTR	Interrupt request signal	In	This signal is for a general purpose interrupt and is sampled only during the last clock cycle of the instruction. When an interrupt is acknowledged, the program counter (PC) is held and an INTA signal is generated. During this cycle, a RESTART or CALL can be inserted to jump to an interrupt service routine. Immediately after an interrupt is accepted it may be enabled and disabled by means of software. The interrupt request is disabled by the RESET.															
\overline{INTA}	Interrupt acknowledge control signal	Out	This signal is used instead of \overline{RD} during the instruction cycle after an INTR is accepted.															
SID	Serial input data	In	This is an input data line for serial data, and the data on this line is moved to the 7th bit of the accumulator whenever a RIM instruction is executed.															
SOD	Serial output data	Out	This is an output data line for serial data. The output SOD may be set or reset by means of the SIM instruction.															

Note: HOLD, READY and all interrupt signals are synchronized with clock signal.

8-BIT PARALLEL MICROPROCESSOR

STATUS INFORMATION

Status information can be obtained directly from the M5L 8085A. ALE is used as a status strobe. As the status is partially encoded, it informs the user in advance what type of bus transfer is being performed. The IO/M cycle status signal is also obtained directly. Decoded S_0 and S_1 signals carry:

	S_1	S_0
HALT	0	0
WRITE	0	1
READ	1	0
FETCH	1	1

S_1 can be used in determining the $\overline{R}/\overline{W}$ status of all bus transfers.

In the M5L 8085A the low-order 8 bits of the address are multiplexed with data. When entering the low-order of the address into memory or peripheral latch circuits, the ALE is used as a strobe.

INTERRUPT AND SERIAL I/O

The M5L 8085A has five interrupt inputs—INTR, RST 5.5, RST 6.5, RST 7.5, and TRAP. INTR has the same function as INT of the M5L 8080A. The three RST inputs, 5.5, 6.5, 7.5, are provided with programmable masks. TRAP has the same function as the restart interrupt, except that it is non-maskable.

When an interrupt is enabled and the corresponding interrupt mask is not set, the three RST interrupts will cause the internal execution of the RST. When nonmaskable TRAP is applied, it causes the internal execution of an RST regardless of the state of the interrupt enable or masks. The restart addresses (hexadecimal) of the interrupts are:

Interrupt	Address
TRAP	24 ₁₆
RST 5.5	2C ₁₆
RST 6.5	34 ₁₆
RST 7.5	3C ₁₆

Two different types of signal are used for restart interrupts. Both RST 5.5 and RST 6.5 are sensitive to high-level as in INTR and INT of the M5L 8080A, and are acknowledged in the same timing as INTR. RST 7.5 is sensitive to rising-edge, and existence of a pulse sets the

RST 7.5 interrupt request. This condition will be maintained until the request is fulfilled or reset by a SIM or RESET instruction.

Each of the restart interrupts may be masked independently to avoid interrupting the CPU. An interrupt requested by an RST 7.5 will be stored even when its mask is set and the interrupt is disabled. Masks can only be changed in the RESET mode. When two enabled interrupts are requested at the same time the interrupt with the highest priority will be accepted. The TRAP has the highest priority followed in order by RST 7.5, RST 6.5, RST 5.5 and INTR. This priority system does not take into consideration the priority of an interrupt routine that is already started. In other words, when an RST 5.5 interrupt is reenabled before the termination of the RST 7.5 interrupt routine, it will interrupt the RST 7.5.

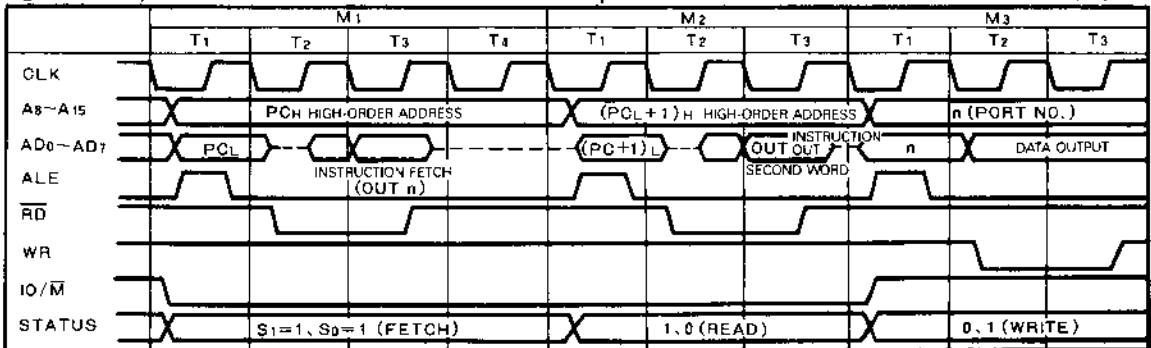

The TRAP interrupt is very useful in preventing disastrous errors and bus errors resulting from power failures. The TRAP input is recognized in the same manner as any other interrupt, but it has the highest priority, and is not affected by any flags or masks. The TRAP input can be sensed by either edge or level. TRAP should be maintained high-level until it is acknowledged. But, it will not be acknowledged again unless it turns low and high again. In this manner, faulty operation due to noise or logic glitches is prevented.

The serial I/O system is also considered to be an interrupt as it is controlled by instructions RIM and SIM. The SID is read by instruction RIM and the SOD data is set by instruction SIM.

BASIC TIMING

The M5L 8085A is provided with a multiplexed data bus. The ALE is utilized as a strobe with which the low-order 8 bits of the address on the data bus are sampled. Fig.1 shows the basic cycle in which an out instruction is fetched, and memory is read and written to the I/O port. The I/O port address is stored in both the address bus and the address/data bus during the I/O write and read cycle. To enable the M5L 8085A to be used with a slow memory, the READY line is used for extending the read and write pulse width in the same manner as in the M5L 8080A.

This list shows the machine codes and corresponding machine instruction. D₃ - D₀ indicate the low-order 4 bits of the machine code and D₇ - D₄ indicate the high-order 4 bits. Hexadecimal numbers are also used to indicate

this code. The instruction may consists of one, two, or three bytes, but only the first byte is listed.

▨ indicates a three-byte instruction.

■ indicates a two-byte instruction.

TRAP INTERRUPT AND RIM INSTRUCTIONS

TRAP generates interrupts regardless of the interrupt enable flip-flop (INTE FF). The current state of the INTE FF is stored in flip flop A (AFF) of the CPU and then the INTE FF is reset. The first RIM instruction after the generation of a TRAP interrupt differs in function from the ordinary RIM instruction. That is, the bit 3 (INTE FF information) in the accumulator ((A)₃) after the execution of the RIM instruction contains the contents of the AFF, regardless of the state of the INTE FF at the time the RIM instruction is executed. These details are shown in Fig. 2, Tables 1 and 2.

Fig. 2 TRAP interrupt processing

Below are the explanations of Fig. 2.

1. The TRAP interrupt request is issued while the instruction in address a is being executed.
2. The TRAP interrupt causes the same action as an RST instruction and then jumps to address 2416.
3. It returns to address a+1 after executing the RET instruction.

Table 1 shows the information in the INTE FF when the instructions EI and/or DI are executed at addresses a-1 and a+2.

Fig. 3 is a flow chart of the TRAP interrupt processing routine.

Fig. 3 TRAP interrupt processing routine

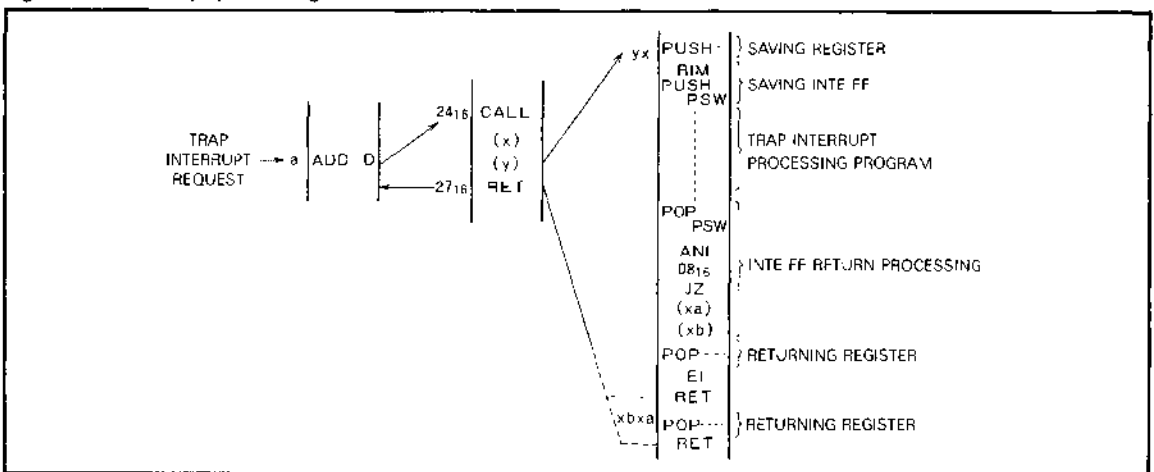

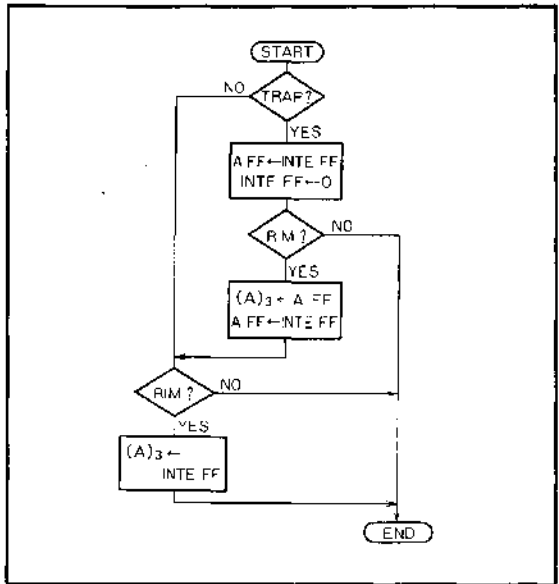

Table 2 TRAP interrupt and RIM instructions

Condition	Number	1	2	3	4	5	6
Instruction in address a-1		EI	EI	EI	DI	DI	DI
Instruction in address a+2		EI	NOP	DI	EI	NOP	DI
Contents of (A) ₃ after the execution of the RIM instruction in address a+3		1	1	1	0	0	0
State of INTE FF after the execution of the RIM instruction in address a+3		1	0	0	1	0	0
Contents of (A) ₃ after the execution of the RIM instruction in address a+4		1	0	0	1	0	0
State of INTE FF after the execution of the RIM instruction in address a+4		1	0	0	1	0	0

Note 3. The contents of (A)₃ after the execution of the RIM instruction is an information of the INTE FF. The INTE FF assumes state "1" when it is in the EI state, and "0" when it is in the DI state.

Table 3 TRAP interrupt and INTE FF processing

8-BIT PARALLEL MICROPROCESSOR

PULL-UP OF THE RESET IN INPUT

In order to increase the noise margin, the RESET IN input terminal is pulled up by about 3kΩ (typ) when the condition $V_I \geq V_{IH(RFSET)}$ is satisfied. Fig. 4 is a connection diagram of the RESET IN input, and Fig. 5 shows the relation between input voltage and input current.

Fig. 4 Connections of RESET IN input

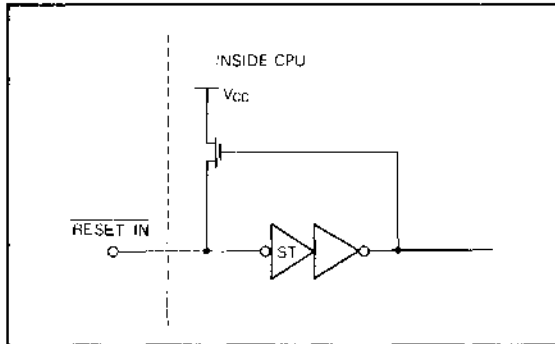

Fig. 5 RESET IN input current vs input voltage

DRIVING CIRCUIT OF X1 AND X2 INPUTS

Input terminals, X1 and X2 of the M5L 8085A can be driven by either a crystal, RC network, or external clock. Since the drive clock frequency is divided to 1/2 internally, the input frequency required is twice the actual execution frequency (6MHz for the M5L 8085A, which is operated at 3MHz). Figs. 6 and 7 are typical connection diagrams for a crystal and CR circuit respectively.

Fig. 6 Connections when crystal is used for X1 and X2 inputs

Fig. 7 Connections when RC network is used for X1 and X2 inputs

Conditions for Using a Quartz Crystal Element

1. Quartz Crystal Specifications

- Parallel resonance
- The frequency is 2 times the operation frequency (2~6.25MHz)
- Internal load capacitance: Approx. 16pF
- Parallel capacitance: Below 7pF
- Equivalent resistance: Below 75Ω (for operation above 4MHz)
- For operation in the range 2~4MHz, the resistance should be made as small as possible.
- Drive capability: Above 5mW (the power at which the crystal will be destroyed)

2. External Circuitry

- For operation above 4MHz:
 $C_1 = C_2 = 10\text{pF}$
- For operation below 4MHz:
 $C_1 = C_2 = 15\text{pF}$

8-BIT PARALLEL MICROPROCESSOR

WAIT STATE GENERATOR

Fig. 8 shows a typical 1-wait state generator for low speed RAM and ROM applications.

RELATION OF RIM AND SIM INSTRUCTIONS WITH THE ACCUMULATOR (SUPPLEMENTARY DESCRIPTION).

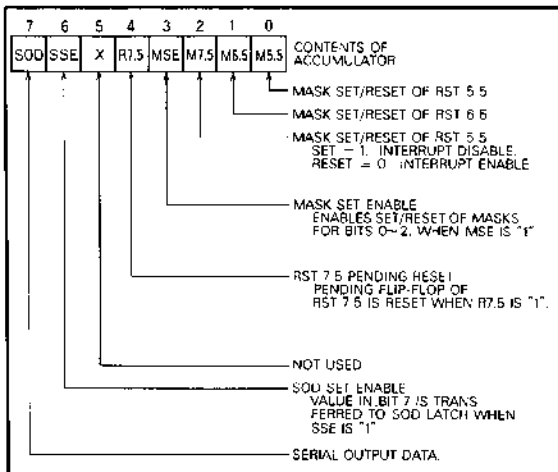

The contents of the accumulator after the execution of a RIM instruction is shown in Table 4.

Table 4 Relation of the instruction RIM with the accumulator

The contents of the accumulator after the execution of a SIM instruction is shown in Table 5.

Table 5 Relation of the SIM instruction with the accumulator

8-BIT INPUT/OUTPUT PORT WITH 3-STATE OUTPUT

DESCRIPTION

The M5L8212P is an input/output port consisting of an 8-bit latch with 3-state output buffers along with control and device selection logic. Also included is a service request flip-flop for the generation and control of interrupts to a microprocessor. It is fabricated using bipolar Schottky TTL technology.

FEATURES

- Parallel 8-bit data register and buffer
- Service request flip-flop for interrupt generation
- Three-state outputs
- Low input load current: $I_{IL} = \text{absolute } -250\mu\text{A (max)}$
- High output sink current: $I_{OL} = 16\text{mA (max)}$
- High-level output voltage for direct interface to a M5L8080AP, S CPU: $V_{OH} = 3.65\text{V (min)}$
- Interchangeable with Intel's 8212 in terms of electrical characteristics and pin configuration

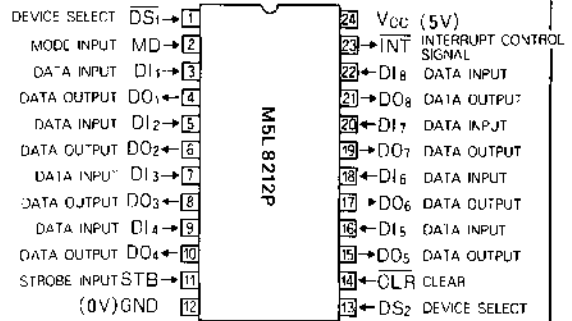

APPLICATIONS

- Input/output port for a M5L8080AP, S
- Latches, gate buffers or multiplexers
- Peripheral and input/output functions for microcomputer systems

FUNCTION

Device select 1 (\overline{DS}_1) and device select 2 (DS_2) are used for chip selection when the mode input MD is low. When \overline{DS}_1 is low and DS_2 is high, the data in the latches is transferred to the data outputs $DO_1 \sim DO_8$, and the service

PIN CONFIGURATION (TOP VIEW)

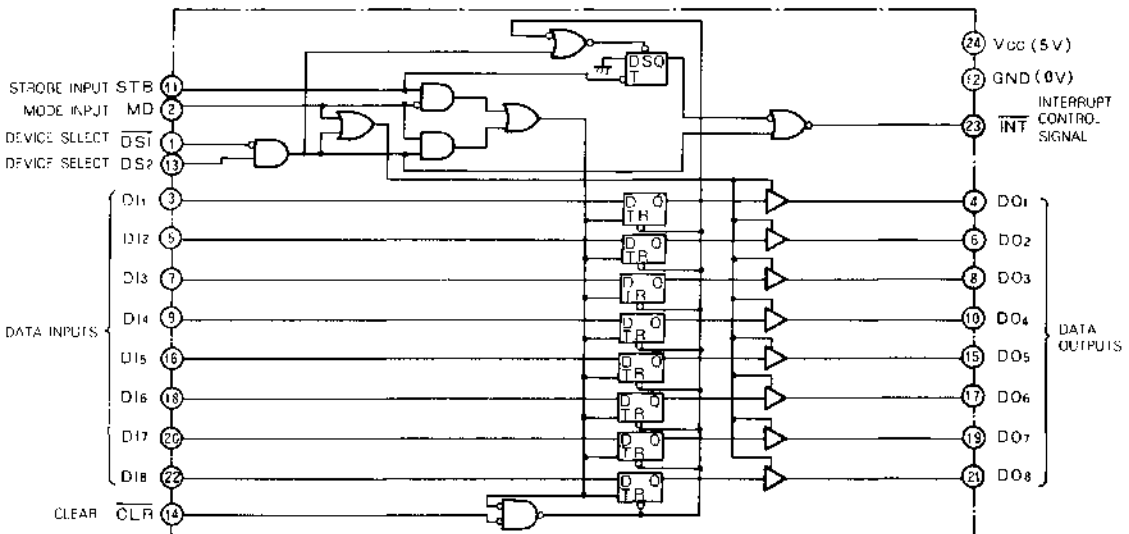

Outline 24P1

request flip-flop SR is set. Also, the strobed input STB is active, the data inputs $DI_1 \sim DI_8$ are latched in the data latches, and the service request flip-flop SR is reset.

When MD is high, the data in the data latches is transferred to the data outputs. When \overline{DS}_1 is low and DS_2 is high, the data inputs are latched in the data latches. The low-level clear input \overline{CLR} resets the data latches and sets the service request flip-flop SR, but the state of the output buffers is not changed.

I _{OZ}	Three-state output current	V _{CC} = 5.25V, V _{IH} = 2V, V _{IL} = 0.85V, V _O = 0.5V			20	μA
I _{IH}	High-level input current, STB, DS2, \overline{CLR} , D11 ~ D18 inputs	V _{CC} = 5.25V, V _I = 5.25V			10	μA
I _{IH}	High-level input current, MD input	V _{CC} = 5.25V, V _I = 5.25V			30	μA
I _{IH}	High-level input current, $\overline{DS1}$ input	V _{CC} = 5.25V, V _I = 5.25V			40	μA
I _{IL}	Low-level input current, STB, DS2, \overline{CLR} , D11 ~ D18 inputs	V _{CC} = 5.25V, V _I = 0.5V			-0.25	mA
I _{IL}	Low-level input current, MD input	V _{CC} = 5.25V, V _I = 0.5V			-0.75	mA
I _{IL}	Low-level input current, $\overline{DS1}$ input	V _{CC} = 5.25V, V _I = 0.5V			-1	mA
I _{OS}	Short-circuit output current (Note 3)	V _{CC} = 5.25V	-20		-65	mA
I _{CC}	Supply current from V _{CC}	V _{CC} = 5.25V			130	mA

Note 1: All voltages are with respect to GND terminal. Reference voltage (pin 12) is considered as 0V and all maximum and minimum values are defined in absolute values.

2: Current flowing into an IC is positive, out is negative. The maximum and minimum values are defined in absolute values.

3: All measurements should be done quickly, and two outputs should not be measured at the same time.

TIMING REQUIREMENTS (Ta = 25°C, V_{CC} = 5V, unless otherwise noted)

Symbol	Parameter	Test conditions	Limits			Unit
			Min	Typ	Max	
t _w (DS2)	Input pulse width, $\overline{DS1}$, DS2 and STB		30			ns

TIMING DIAGRAMS REFERENCE LEVEL -1.5V

MITSUBISHI BIPOLAR DIGITAL ICs

M5L8216P, M5L8226P

4-BIT PARALLEL BIDIRECTIONAL BUS DRIVERS

DESCRIPTION

The M5L8216P and M5L8226P are 4-bit bidirectional bus drivers and suitable for the 8-bit parallel CPU M5L8080AP, S (8080A). They are fabricated by using bipolar Schottky TTL technology, and have high fan-out.

FEATURES

- Parallel 8-bit data bus buffer driver
- Low input current \overline{DIEN} , \overline{CS} :
 $I_{IL} = -500\mu A(\max)$
 $I_{IL} = -250\mu A(\max)$
- High output current M5L8216P
 DB: $I_{OL} = 55mA(\max)$
 $I_{OH} = -10mA(\max)$
 DO: $I_{OH} = -1mA(\max)$
 M5L8226P
 DB: $I_{OL} = 50mA(\max)$
 $I_{OH} = -10mA(\max)$
 DO: $I_{OH} = -1mA(\max)$
- Outputs can be connected with the CPU M5L8080AP, S: $V_{OH} = 3.65V(\min)$
- Three-state output
- The M5L8216P has interchangeability with Intel's 8216 in pin configuration and electrical characteristics, and the M5L8226P with Intel's 8226.

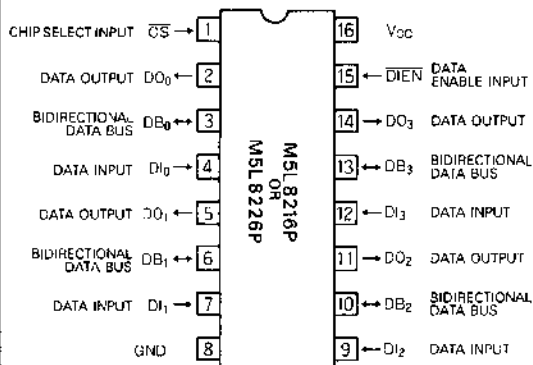

APPLICATION

Bidirectional bus driver/receiver for various types of microcomputer systems.

FUNCTION

The M5L8216P is a noninverting and the M5L8226P is an inverting 4-bit bidirectional bus driver.

PIN CONFIGURATION (TOP VIEW)

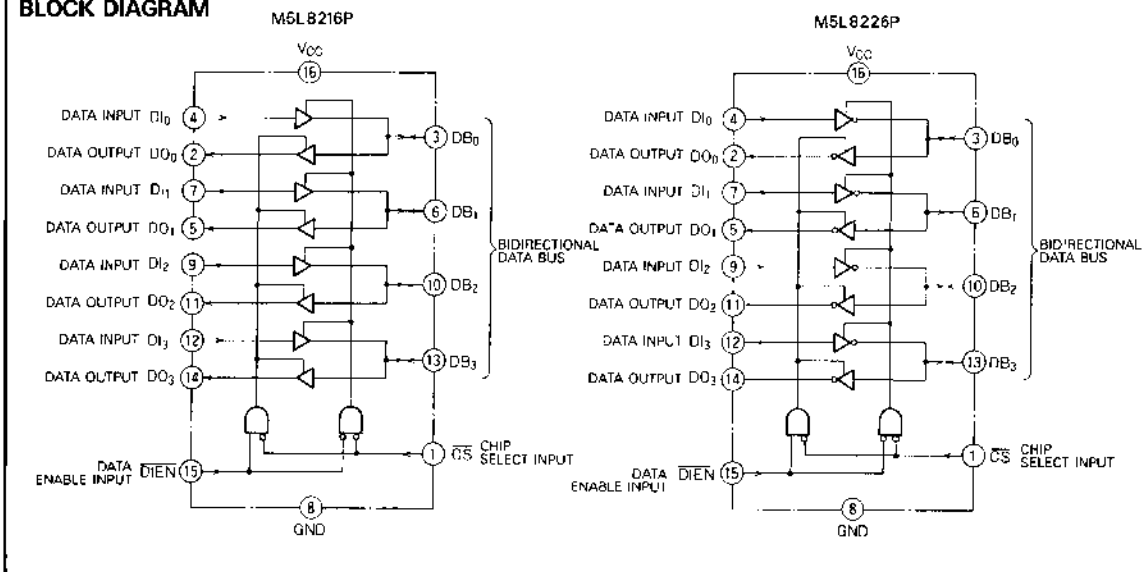

Outline 16P4

When the terminal \overline{CS} is high-level, all outputs are in high-impedance state, and when low-level, the direction of the bidirectional bus can be controlled by the terminal \overline{DIEN} .

The terminal \overline{DIEN} controls the data flow. The data flow control is performed by placing one of a pair of buffers in high-impedance state and allowing the other to transfer the data.

TIMING DIAGRAM (Reference level = 1.5V)

Note 3. Measurement circuit

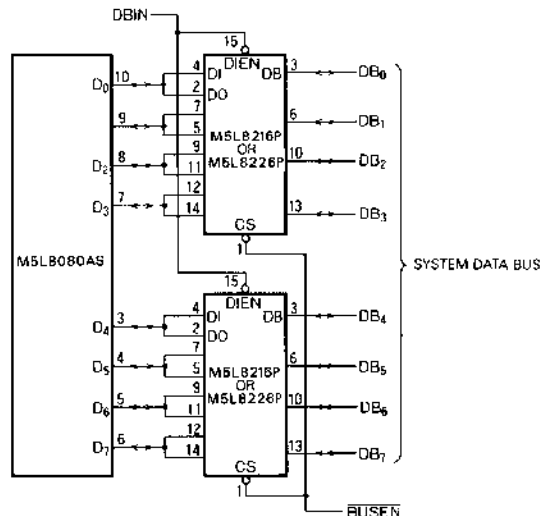

Fig. 1 Data bus buffer

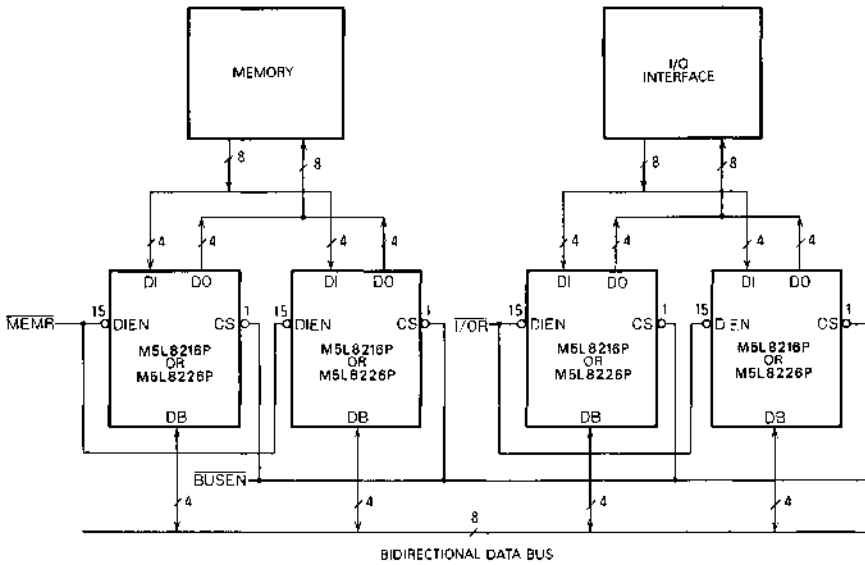

APPLICATION EXAMPLES

Fig. 1 shows a pair of M5L8216PS or M5L8226PS which are directly connected with the M5L8080A CPU data bus, and their control signal. Fig. 2 shows an example circuit in which the M5L8216P or M5L8226P is used as an interface for memory and I/O to a bidirectional bus.

4-BIT PARALLEL BIDIRECTIONAL BUS DRIVERS

Fig. 2 Memory and I/O interface to bidirectional data bus

Precautions for Use

When the M5L8216P data input or two-way data bus is set to high to disable-output from the two-way bus or data output, care is required as a low glitch of approximate width 10nS will be generated.

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

DESCRIPTION

The M5L8155P is a 2K-bit RAM (256-word by 8-bit) fabricated with the N-channel silicon-gate ED-MOS technology. This IC has 3 I/O ports and a 14-bit counter/timer which make it a good choice to extend the functions of an 8-bit microcomputer. It is incased in a 40-pin plastic DIL package and operates with a single 5V power supply.

FEATURES

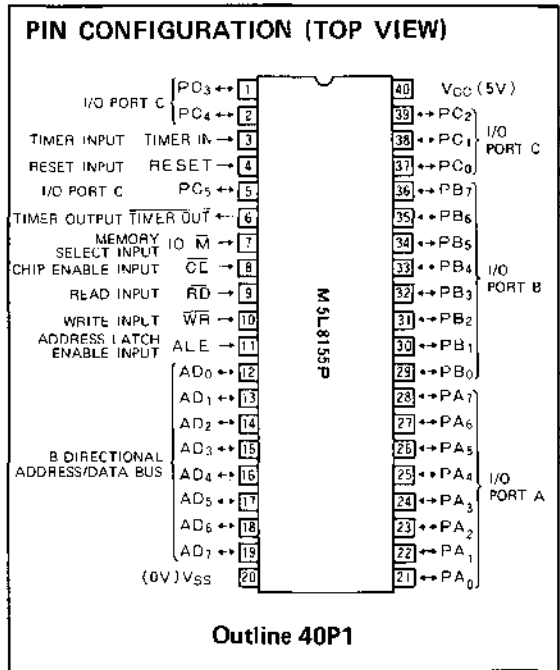

- Compatible with MELPS 85 devices
- Static RAM: 256 words by 8 bits
- Programmable 8-bit I/O port: 2
- Programmable 6-bit I/O port: 1
- Programmable counter/timer: 14 bits
- Multiplexed address/data bus
- Single 5V power supply
- Interchangeable with Intel's P8155 in pin
- Configuration and electrical characteristics

APPLICATION

- Extension of I/O ports and timer function for MELPS 8/85 and MELPS 8-48 devices

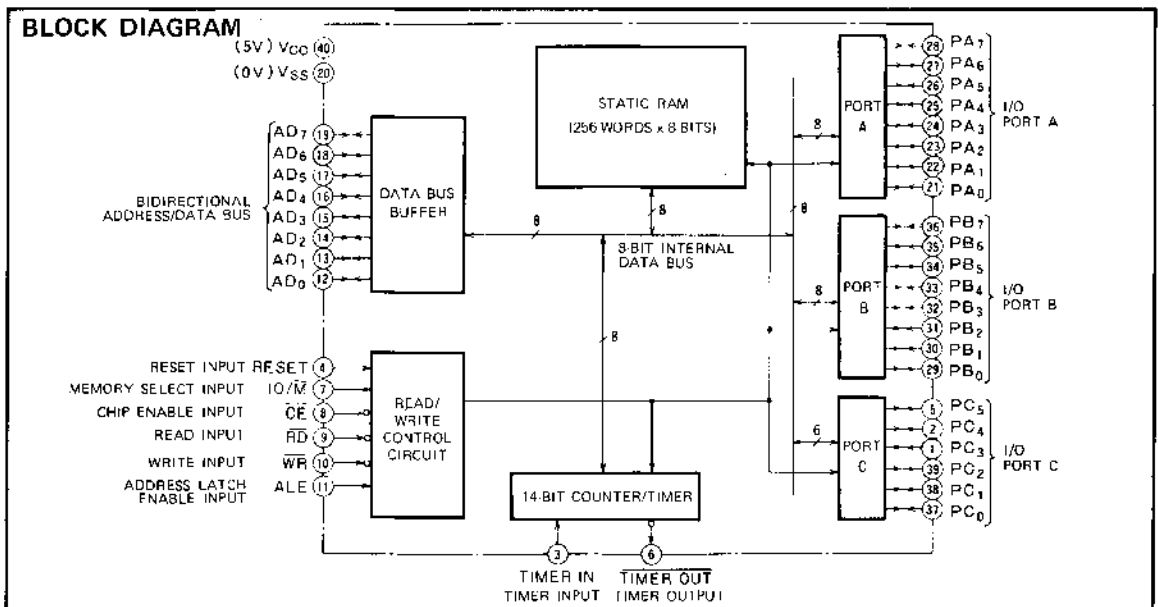

FUNCTION

The M5L8155P is composed of RAM, I/O ports and counter/timer. The RAM is a 2K-bit static RAM organized as 256 words by 8 bits. The I/O ports consist of 2 programmable 8-bit ports and 1 programmable 6-bit port. The terminals of the 6-bit port can be programmed to function

7

as control terminals for the 8-bit ports, so that the 8-bit ports can be operated in a handshake mode. The counter/timer is composed of 14 bits that can be used to count down (events or time) and it can generate square wave pulses that can be used for counting and timing.

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

OPERATION

Data Bus Buffer

This 3-state bidirectional 8-bit buffer is used to transfer the data while input or output instructions are being executed by the CPU. Command and address information is also transferred through the data bus buffer.

Read/Write Control Logic

The read/write control logic controls the transfer of data by interpreting I/O control bus output signals (\overline{RD} , \overline{WR} , IO/\overline{M} and ALE) along with CPU signal (\overline{CE}). RESET signal is also used to control the transfer of data and commands.

Bidirectional Address/Data Bus ($AD_0 \sim AD_7$)

The bidirectional address/data bus is a 3-state 8-bit bus. The 8-bit address is latched in the internal latch by the falling edge of ALE . Then if IO/\overline{M} input signal is at high-level, the address of I/O port, counter/timer, or command register is selected. If it is at low-level, memory address is selected.

The 8-bit address data is transferred by read input (\overline{RD}) or write input (\overline{WR}).

Chip Enable Input (\overline{CE})

When \overline{CE} is at low-level, the address information on address/data bus is stored in the M5L8155P

Read Input (\overline{RD})

When \overline{RD} is at low-level the data bus buffer is active. If IO/\overline{M} input signal is at low-level, the contents of RAM are read through the address/data bus. If IO/\overline{M} input is at high-level, the selected contents of I/O port or counter/timer are read through the address/data bus.

Write Input (\overline{WR})

When \overline{WR} is at low-level, the data on the address/data bus are written into RAM if IO/\overline{M} is at low-level, or if IO/\overline{M} is at high-level they are written into I/O port, counter/timer or command register.

Address Latch Enable Input (ALE)

An address on the address/data bus along with the levels of \overline{CE} and IO/\overline{M} are latched in the M5L8155P on the falling edge of ALE .

IO/Memory Input (IO/\overline{M})

When IO/\overline{M} is at low-level, the RAM is selected, while at high-level the I/O port, counter/timer or command register are selected.

I/O Port A ($PA_0 \sim PA_7$)

Port A is an 8-bit general-purpose I/O port. Input/output setting is controlled by the system software.

I/O Port B ($PB_0 \sim PB_7$)

Port B is an 8-bit general-purpose I/O port. Input/output setting is controlled by the system software.

I/O Port C ($PC_0 \sim PC_2$)

Port C is a 6-bit I/O port that can also be used to output control signals of port A (PA) or port B (PB). The functions of port C are controlled by the system software. When port

C is used to output control signals of ports A or B the assignment of the signals to the pins is as shown in Table 1.

Table 1 Pin assignment of control signals of port C

Pin	Function
PC_5	B STB (port B strobe)
PC_4	B BF (port B buffer full)
PC_3	B INTR (port B interrupt)
PC_2	A STB (port A strobe)
PC_1	A BF (port A buffer full)
PC_0	A INTR (port A interrupt)

Timer Input (TIMER IN)

The signal at this input terminal is used by the counter/timer for counting events or time. (3MHz max.)

Timer Output (TIMER OUT)

A square wave signal or pulse from the counter/timer is output through this pin when in the operation mode.

Command Register (8 bits)

The command register is an 8-bit latched register. The low-order 4 bits (bits 0 ~ 3) are used for controlling and determination of the mode of the ports. Bits 4 and 5 are used as interrupt enable flags for ports A and B when port C is used as a control port. Bits 6 and 7 are used for controlling the counter/timer. The contents of the command register are rewritten by output instructions (address I/O XXXXX000).

Details of the functions of the individual bits of the command register are shown in Fig. 1.

Fig. 1 Bit functions of the command register

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Status Register (7 bits)

The status register is a 7-bit latched register. The low-order 5 bits (bits 0 ~ 4) are used as status flags for the I/O ports. Bit 6 is as a status flag for the counter/timer. The

contents of the status register are transferred into the CPU by reading (INPUT instruction, address I/O XXXXX000). Details of the functions of the individual bits of the status register are shown in Fig. 2.

Fig. 2 Bit functions of the status register

I/O Ports

Command/status registers (8 bits/7 bits)

These registers are assigned address XXXXX000. When executing an OUTPUT instruction, the contents of the command register are rewritten. When executing an INPUT instruction the contents of the status register are read.

Port A Register (8 bits)

Port A register is assigned address XXXXX001. This register can be programmed as an input or output by setting the appropriate bits of the command register as shown in Fig. 1.

Port A can be operated in basic or strobe mode and is assigned I/O terminal PA₀ ~ PA₇.

Port B Register (8 bits)

Port B register is assigned address XXXXX010. As with Port A register, this register can be programmed as an input or output by setting the appropriate bits of the command register as shown in Fig. 1. Port B can be operated in basic or strobe mode and is assigned I/O terminals PB₀ ~ PB₇.

Port C Register (6 bits)

Port C register is assigned address XXXXX011. This port is used for controlling input/output operations of ports A and B by selectively setting bits 2 and 3 of the command register as shown in Fig. 1. Details of the functions of the various setting of bits 2 and 3 are shown in Table 2. Port C is assigned I/O terminals PC₀ ~ PC₅ and when used as port control signals, the 3 low-order bits are assigned for port A while the 3 high-order bits are assigned for port B.

7

Table 2 Functions of port C

State Terminal	ALT 1	ALT 2	ALT 3	ALT 4
PC ₅	Input	Output	Output	B STB (port B strobe)
PC ₄	Input	Output	Output	B BF (port B buffer full)
PC ₃	Input	Output	Output	B INTR (port B interrupt)
PC ₂	Input	Output	A STB (port A strobe)	A STB (port A strobe)
PC ₁	Input	Output	A BF (port A buffer full)	A BF (port A buffer full)
PC ₀	Input	Output	A INTR (port A interrupt)	A INTR (port A interrupt)

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Configuration of Ports

A block diagram of 1 bit of ports A and B is shown in Fig. 3. While port A or B is programmed as an output port, if the port is addressed by an input instruction, the contents of the selected port can be read. When a port is put in input mode, the output latch is cleared and writing into the output latch is disabled. Therefore when a port is changed to output mode from input mode, low-level signals are output through the port. When a reset signal is applied, all 3 ports (PA, PB, and PC) will be input ports and their output latches are cleared. Port C has the same configuration as ports A and B in modes ALT1 and ALT2.

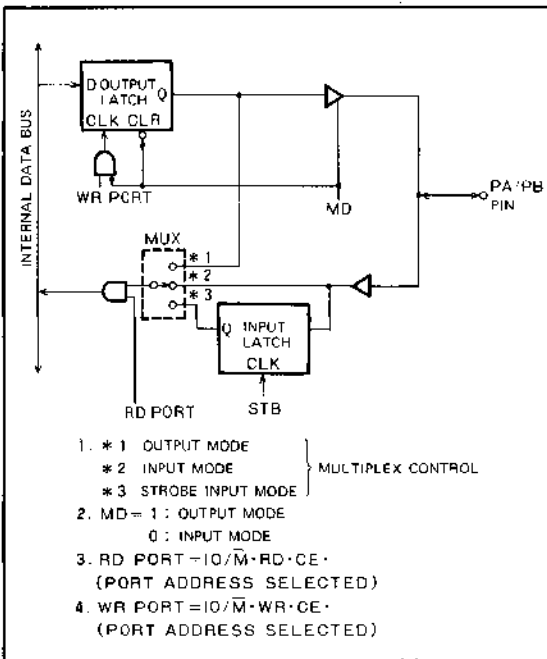

Fig. 3 Configuration for 1 bit of port A or B

The basic functions of the I/O ports are shown in Table 3. The control signal levels to ports A and B, when port C is programmed as a control port, are shown in Table 4.

Table 3 Basic functions of I/O ports

Address	\overline{RD}	WR	Function
XXXXX000	0	1	AD bus ← status register
	1	0	Command register ← AD bus
XXXXX001	0	1	AD bus ← port A
	1	0	Port A ← AD bus
XXXXX010	0	1	AD bus ← port B
	1	0	Port B ← AD bus
XXXXX011	0	1	AD bus ← port C
	1	0	Port C ← AD bus

Table 4 Port control signal levels at ALT3 and ALT4

Control signal	Input mode	Output mode
BF	"L"	"L"
INTR	"L"	"H"
STB	Input	Input

Counter/Timer

The counter/timer is a 14-bit counting register plus 2 mode flags. The register has two sections: address I/O XXXXX100 is assigned to the low-order 8 bits and address I/O XXXXX101 is assigned to the high-order 8 bits. The low-order bits 0 ~ 13 are used for counting or timing. The counter is initialized by the program and then counted down to zero. The initial setting can range from 2_{16} to $3FFF_{16}$. Bits 14 and 15 are used as mode flags.

The mode flags select 1 of 4 modes with functions as follow:

- Mode 0: Outputs high-level signal during the former half of the counter operation
 Outputs low-level signal during the latter half of the counter operation
- Mode 1: Outputs square wave signals as in mode 0
- Mode 2: Outputs a low-level pulse during the final count down
- Mode 3: Outputs a low-level pulse during each final count down

Starting and stopping the counter/timer is controlled by bits 6 and 7 of the command register (see Fig. 1 for details). The format and timer modes of the counter/timer register are shown in Fig. 4 and Table 5.

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Fig. 4 Format of counter/timer

The counter/timer is not influenced by a reset, but counting is discontinued. To resume counting, a start command must be written into the command register as shown in Fig. 1. While operating 2n+1 count down in mode 0, a high-level signal is output during the n+1 counting and a low-level signal is output during the n counting.

Table 5 Timer mode

M ₂	M ₁	Timer operation
0	0	Outputs high-level signal during the former half of the counter operation Outputs low-level signal during the latter half of the counter operation (mode 0)
0	1	Outputs square wave signals as in mode 0 (mode 1)
1	0	Outputs a low-level pulse during the final count down (mode 2)
1	1	Outputs a low-level pulse during each final count down (mode 3)

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

DESCRIPTION

The M5L8156P is a 2K-bit RAM (256-word by 8-bit) fabricated with the N-channel silicon-gate ED-MOS technology. This IC has 3 I/O ports and a 14-bit counter/timer which make it a good choice to extend the functions of an 8-bit microcomputer. It is incased in a 40-pin plastic DIL package and operates with a single 5V power supply.

FEATURES

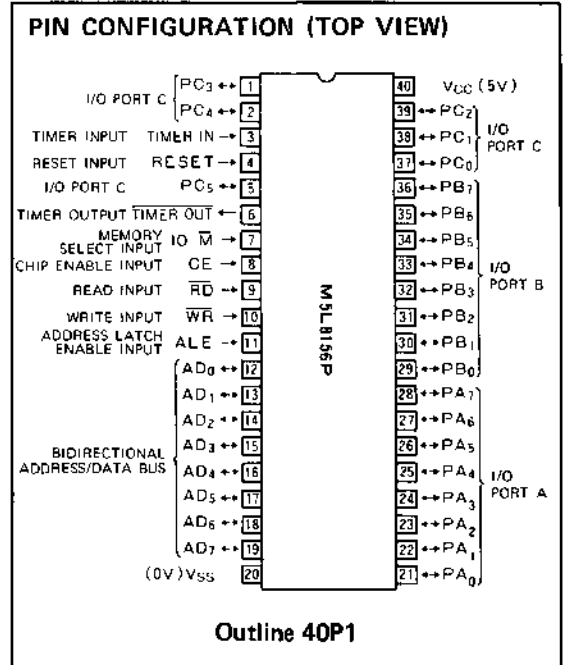

- Compatible with MELPS 85 devices
- Static RAM: 256 words by 8 bits
- Programmable 8-bit I/O port: 2
- Programmable 6-bit I/O port: 1
- Programmable counter/timer: 14 bits
- Multiplexed address/data bus
- Single 5V power supply
- Interchangeable with Intel's P8156 in pin
- Configuration and electrical characteristics

APPLICATION

- Extension of I/O ports and timer function for MELPS 8/85 and MELPS 8-48 devices

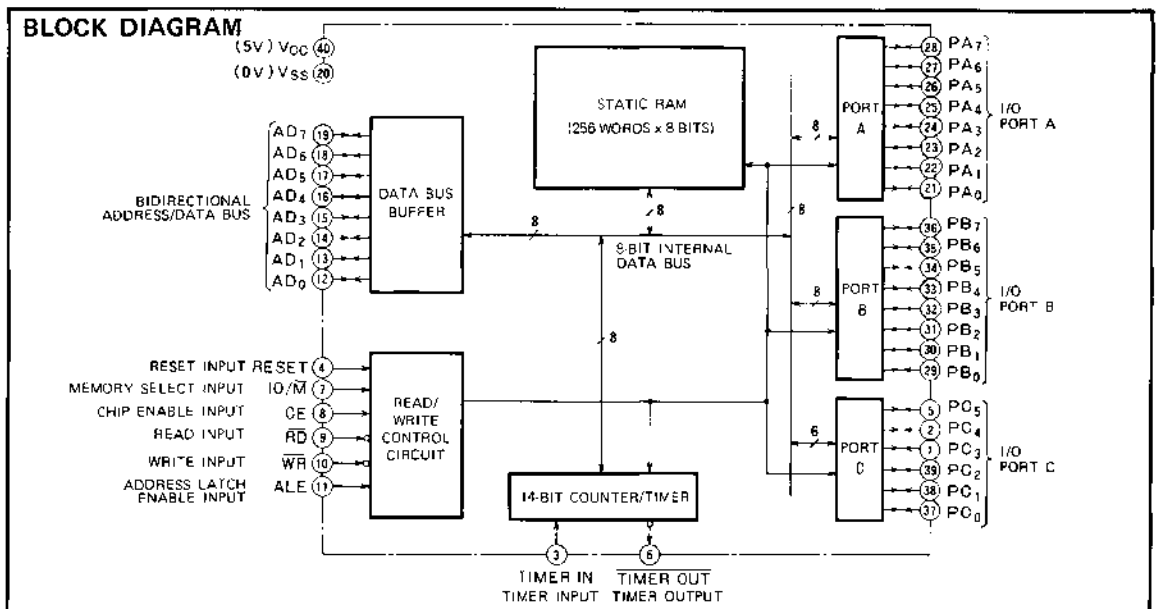

FUNCTION

The M5L8156P is composed of RAM, I/O ports and counter/timer. The RAM is a 2K-bit static RAM organized as 256 words by 8 bits. The I/O ports consist of 2 programmable 8-bit ports and 1 programmable 6-bit port. The terminals of the 6-bit port can be programmed to function

7

as control terminals for the 8-bit ports, so that the 8-bit ports can be operated in a handshake mode. The counter/timer is composed of 14 bits that can be used to count down (events or time) and it can generate square wave pulses that can be used for counting and timing.

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

OPERATION

Data Bus Buffer

This 3-state bidirectional 8-bit buffer is used to transfer the data while input or output instructions are being executed by the CPU. Command and address information is also transferred through the data bus buffer.

Read/Write Control Logic

The read/write control logic controls the transfer of data by interpreting I/O control bus output signals (\overline{RD} , \overline{WR} , $\overline{IO/\overline{M}}$ and ALE) along with CPU signal (CE). RESET signal is also used to control the transfer of data and commands.

Bidirectional Address/Data Bus ($AD_0 \sim AD_7$)

The bidirectional address/data bus is a 3-state 8-bit bus. The 8-bit address is latched in the internal latch by the falling edge of ALE. Then if $\overline{IO/\overline{M}}$ input signal is at high-level, the address of I/O port, counter/timer, or command register is selected. If it is at low-level, memory address is selected.

The 8-bit address data is transferred by read input (\overline{RD}) or write input (\overline{WR}).

Chip Enable Input (CE)

When CE is at high-level, the address information on address/data bus is stored in the M5L8156P.

Read Input (\overline{RD})

When \overline{RD} is at low-level the data bus buffer is active. If $\overline{IO/\overline{M}}$ input signal is at low-level, the contents of RAM are read through the address/data bus. If $\overline{IO/\overline{M}}$ input is at high-level, the selected contents of I/O port or counter/timer are read through the address/data bus.

Write Input (\overline{WR})

When \overline{WR} is at low-level, the data on the address/data bus are written into RAM if $\overline{IO/\overline{M}}$ is at low-level, or if $\overline{IO/\overline{M}}$ is at high-level they are written into I/O port, counter/timer or command register.

Address Latch Enable Input (ALE)

An address on the address/data bus along with the levels of CE and $\overline{IO/\overline{M}}$ are latched in the M5L8156P on the falling edge of ALE.

IO/Memory Input ($\overline{IO/\overline{M}}$)

When $\overline{IO/\overline{M}}$ is at low-level, the RAM is selected, while at high-level the I/O port, counter/timer or command register are selected.

I/O Port A ($PA_0 \sim PA_7$)

Port A is an 8-bit general-purpose I/O port. Input/output setting is controlled by the system software.

I/O Port B ($PB_0 \sim PB_7$)

Port B is an 8-bit general-purpose I/O port. Input/output setting is controlled by the system software.

I/O Port C ($PC_0 \sim PC_5$)

Port C is a 6-bit I/O port that can also be used to output control signals of port A (PA) or port B (PB). The functions of port C are controlled by the system software. When port

C is used to output control signals of ports A or B the assignment of the signals to the pins is as shown in Table 1.

Table 1 Pin assignment of control signals of port C

Pin	Function
PC ₅	B STB (port B strobe)
PC ₄	B BF (port B buffer full)
PC ₃	B INTR (port B interrupt)
PC ₂	A STB (port A strobe)
PC ₁	A BF (port A buffer full)
PC ₀	A INTR (port A interrupt)

Timer Input (TIMER IN)

The signal at this input terminal is used by the counter/timer for counting events or time. (3MHz max.)

Timer Output (TIMER OUT)

A square wave signal or pulse from the counter/timer is output through this pin when in the operation mode.

Command Register (8 bits)

The command register is an 8-bit latched register. The low-order 4 bits (bits 0 ~ 3) are used for controlling and determination of the mode of the ports. Bits 4 and 5 are used as interrupt enable flags for ports A and B when port C is used as a control port. Bits 6 and 7 are used for controlling the counter/timer. The contents of the command register are rewritten by output instructions (address I/O XXXXX000).

Details of the functions of the individual bits of the command register are shown in Fig. 1.

Fig. 1 Bit functions of the command register

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Status Register (7 bits)

The status register is a 7-bit latched register. The low-order 5 bits (bits 0 ~ 4) are used as status flags for the I/O ports. Bit 6 is as a status flag for the counter/timer. The

contents of the status register are transferred into the CPU by reading (INPUT instruction, address I/O XXXXX000). Details of the functions of the individual bits of the status register are shown in Fig. 2.

Fig. 2 Bit functions of the status register

I/O Ports

Command/status registers (8 bits/7 bits)

These registers are assigned address XXXXX000. When executing an OUTPUT instruction, the contents of the command register are rewritten. When executing an INPUT instruction the contents of the status register are read.

Port A Register (8 bits)

Port A register is assigned address XXXXX001. This register can be programmed as an input or output by setting the appropriate bits of the command register as shown in Fig. 1.

Port A can be operated in basic or strobe mode and is assigned I/O terminal PA₀ ~ PA₇.

Port B Register (8 bits)

Port B register is assigned address XXXXX010. As with Port A register, this register can be programmed as an input or output by setting the appropriate bits of the command register as shown in Fig. 1. Port B can be operated in basic or strobe mode and is assigned I/O terminals PB₀ ~ PB₇.

Port C Register (6 bits)

Port C register is assigned address XXXXX011. This port is used for controlling input/output operations of ports A and B by selectively setting bits 2 and 3 of the command register as shown in Fig. 1. Details of the functions of the various setting of bits 2 and 3 are shown in Table 2. Port C is assigned I/O terminals PC₀ ~ PC₅ and when used as port control signals, the 3 low-order bits are assigned for port A while the 3 high-order bits are assigned for port B.

7

Table 2 Functions of port C

State Terminal	ALT 1	ALT 2	ALT 3	ALT 4
PC ₅	Input	Output	Output	\overline{B} STB (port B strobe)

PC ₀	Input	Output	A INTR (port A interrupt)	A INTR (port A interrupt)

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Configuration of Ports

A block diagram of 1 bit of ports A and B is shown in Fig. 3. While port A or B is programmed as an output port, if the port is addressed by an input instruction, the contents of the selected port can be read. When a port is put in input mode, the output latch is cleared and writing into the output latch is disabled. Therefore when a port is changed to output mode from input mode, low-level signals are output through the port. When a reset signal is applied, all 3 ports (PA, PB, and PC) will be input ports and their output latches are cleared. Port C has the same configuration as ports A and B in modes ALT1 and ALT2.

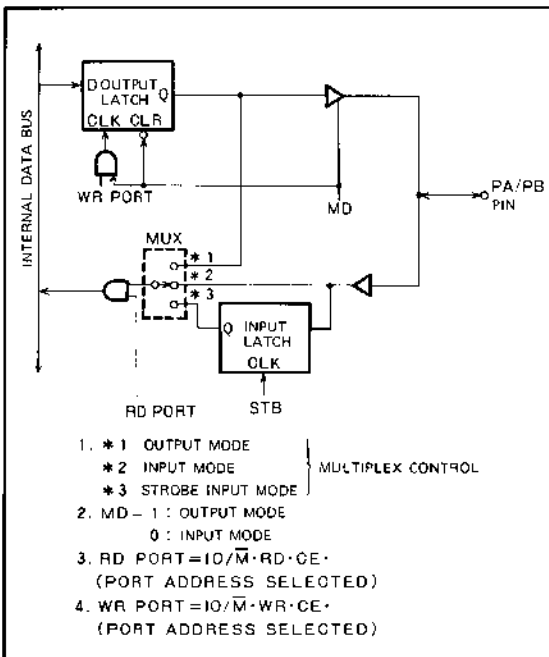

Fig. 3 Configuration for 1 bit of port A or B

The basic functions of the I/O ports are shown in Table 3. The control signal levels to ports A and B, when port C is programmed as a control port, are shown in Table 4.

Table 3 Basic functions of I/O ports

Address	\overline{RD}	\overline{WR}	Function
XXXXX000	0	1	AD bus ← status register
	1	0	Command register ← AD bus
XXXXX001	0	1	AD bus ← port A
	1	0	Port A ← AD bus
XXXXX010	0	1	AD bus ← port B
	1	0	Port B ← AD bus
XXXXX011	0	1	AD bus ← port C
	1	0	Port C ← AD bus

Table 4 Port control signal levels at ALT3 and ALT4

Control signal	Input mode	Output mode
BF	"L"	"L"
INTR	"L"	"H"
\overline{STB}	Input	Input

Counter/Timer

The counter/timer is a 14-bit counting register plus 2 mode flags. The register has two sections: address I/O XXXXX100 is assigned to the low-order 8 bits and address I/O XXXXX101 is assigned to the high-order 8 bits. The low-order bits 0 ~ 13 are used for counting or timing. The counter is initialized by the program and then counted down to zero. The initial setting can range from 2_{16} to $3FF_{16}$. Bits 14 and 15 are used as mode flags.

The mode flags select 1 of 4 modes with functions as follow:

- Mode 0: Outputs high-level signal during the former half of the counter operation
 Outputs low-level signal during the latter half of the counter operation
- Mode 1: Outputs square wave signals as in mode 0
- Mode 2: Outputs a low-level pulse during the final count down
- Mode 3: Outputs a low-level pulse during each final count down

Starting and stopping the counter/timer is controlled by bits 6 and 7 of the command register (see Fig. 1 for details). The format and timer modes of the counter/timer register are shown in Fig. 4 and Table 5.

2048-BIT STATIC RAM WITH I/O PORTS AND TIMER

Fig. 4 Format of counter/timer

The counter/timer is not influenced by a reset, but counting is discontinued. To resume counting, a start command must be written into the command register as shown in Fig. 1. While operating 2n+1 count down in mode 0, a high-level signal is output during the n+1 counting and a low-level signal is output during the n counting.

Table 5 Timer mode

M ₂	M ₁	Timer operation
0	0	Outputs high-level signal during the former half of the counter operation. Outputs low-level signal during the latter half of the counter operation. (mode 0)
0	1	Outputs square wave signals as in mode 0. (mode 1)
1	0	Outputs a low-level pulse during the final count down. (mode 2)
1	1	Outputs a low-level pulse during each final count down. (mode 3)

LSIs FOR PERIPHERAL CIRCUITS

8-BIT 8-CHANNEL A-D CONVERTER

DESCRIPTION

The M58990P A-D converter is used to convert analog signals to 8-bit digital values. The A-D converter is fabricated using silicon-gates and CMOS technology. The M58990P can selectively multiplex 8 channels of analog input.

FEATURES

- Single 5V power supply
- Conversion resolution of 8 bits
- Multiplex 8 channels of analog input
- Broad range of analog input voltages: 0V ~ V_{CC}
- Conversion time: 100μs
- Conversion by successive approximation
- Can be used online through the data bus of a microprocessor
- The I/O pins can be connected directly to TTL circuits
- Interchangeable with NS's ADC0808 (in pin configuration)

APPLICATION

- Used with microcomputers to control analog systems

FUNCTION

The M58990P has eight analog input terminals that are selected by the input signals to the 3 address terminals (ADD A ~ ADD C). The address signals of these terminals are read and latched in the internal address latches by the ALE signal. When the OE terminal is at low-level, the output terminals 2⁻¹ ~ 2⁻⁸ are in a floating state so they can be connected directly to the data bus of a microcomputer.

PIN CONFIGURATION (TOP VIEW)

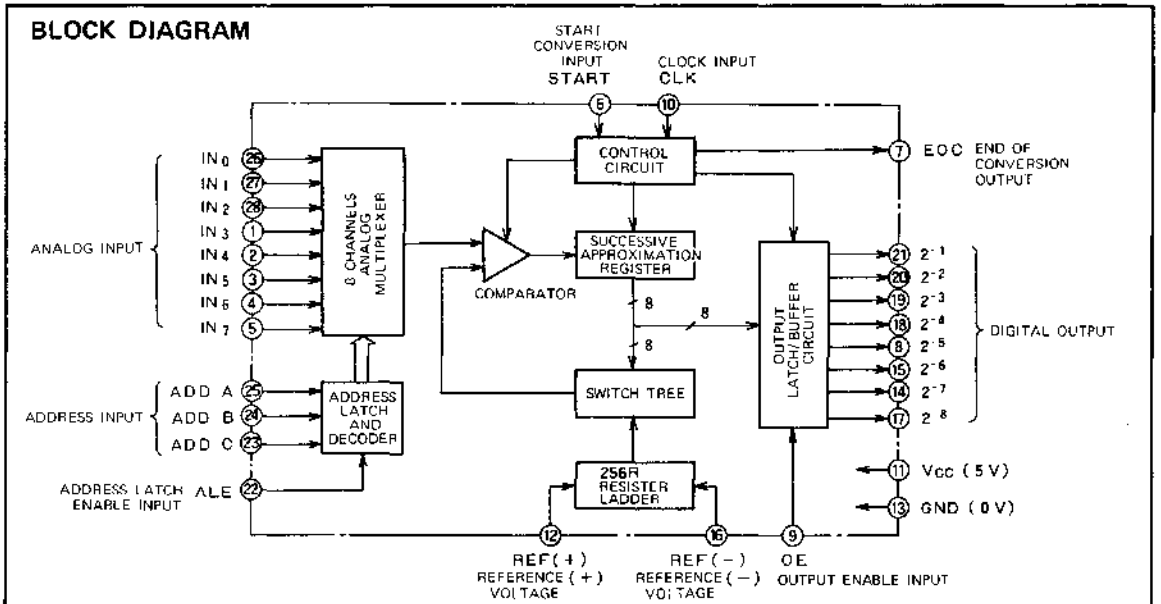

Outline 28P 4

The input terminal START is used to call for the start of an analog to digital conversion and a signal is output through terminal EOC when the conversion is completed.

BLOCK DIAGRAM

8-BIT 8-CHANNEL A-D CONVERTER

PIN DESCRIPTIONS

Pin	Name	Input or Output	Functions
IN ₀ ┆ IN ₇	Analog signal	Input	These are analog signal input pins. Which of the 8 inputs is selected, is determined by ADD A ~ ADD C. An analog voltage applied at the selected pin is converted to a digital value in the range of 2 ⁻¹ ~ 2 ⁻⁸ and output.
ADD A ┆ ADD C	Address signal	Input	The input is used for selecting which of the 8 terminals IN ₀ ~ IN ₇ is to be converted from analog to digital. The address input through ADD A ~ ADD C is read to the address latch by the rising edge of ALE.
ALE	Address latch enable signal	Input	This is the strobe signal which causes the address signal input through ADD A ~ ADD C to be read and latched for use as an internal address.
REF (+)	Reference voltage (+)	Input	This is one of the input terminals for the reference voltage that is applied to the 256R resistor ladder circuit. The other terminal is REF (-) and the voltage levels of these two inputs must meet the condition: REF (+) > REF (-).
REF (-)	Reference voltage (-)	Input	This is one of the input terminals for the reference voltage that is applied to the 256R resistor ladder circuit. The other terminal is REF (+) and the voltage levels of these two inputs must meet the condition: REF (+) > REF (-).
OE	Output enable signal	Input	The signal at this pin controls the digital output. When the signal is low-level, pins 2 ⁻¹ ~ 2 ⁻⁸ are in a floating state. When it is high-level, the data is output.
2 ⁻¹ ┆ 2 ⁻⁸	Digital signal	Output	The analog signal, which was input through IN ₀ ~ IN ₇ , is converted to digital data and is output from these terminals. When OE is low-level, these terminals are floating. When OE is high-level, the converted digital data is output. The MSB is 2 ⁻¹ and the LSB is 2 ⁻⁸ .
EOC	End of conversion signal	Output	This terminal is used to indicate the completion of an analog to digital conversion. It is reset by a START signal (high-level to low-level) and is set on completion of the conversion (low-level to high-level). This output is normally used to generate an interrupt request for the CPU.
START	Start conversion signal	Input	The input signal at this terminal is used to start a conversion cycle by setting the successive approximation register. The successive approximation register is reset by rising from low-level to high-level and conversion is started after being set by falling from high-level to low-level.
CLK	Clock input	Input	The signal at this terminal is the basic clocking signal used to determine internal timing.

TIMING DIAGRAM

VIDEO DISPLAY GENERATOR

DESCRIPTION

The M5C6847P-1 is a color or monochrome television interface device, fabricated using N-channel silicon gate ED-MOS technology. The M5C6847P-1 has a 64-character (6-bit ASCII code) generator and memory interface.

FEATURES

- Can be easily connected to the MELPS 85 series 8-bit CPUs.
- Alphanumeric display: 4 modes
- Graphic display: 8 modes
- Can connect directly with the M51342P RF modulator
- Alphanumeric display: 32 characters per line by 16 lines
- Character generator for 64 ASCII characters
- Can be used with an external character generator
- Generates composite video signals
- Generates intensity signal Y, color signal R-Y (ϕA) and B-Y (ϕB)
- Display RAM capacity (depends on mode): 512~6K bytes
- Single 5V power supply
- Interchangeable with the Motorola's MC6847P in pin configuration

APPLICATION

- Microcomputer system or terminals using a color or monochrome CRT.

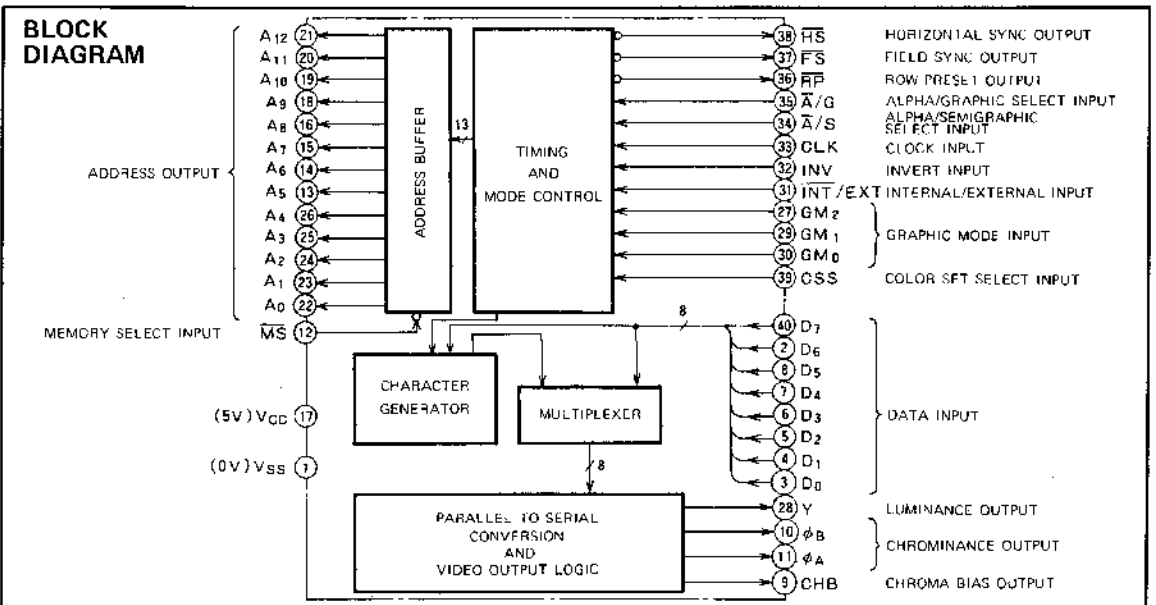

FUNCTION

The picture on the television set is composed of the syn-

chronization signals such as horizontal synchronization signal, vertical synchronization signal and color burst signal, and synchronizing serial data. M5C6847P-1 can generate these signals. The information or data to be shown on the screen is written in the display memory by the CPU. (When the picture is to be composed on a CRT) the data for one screen in the display memory is read in the order of the scan cycles and synchronization signals are added. This

8

VIDEO DISPLAY GENERATOR

serial is sent to the RF modulator. The M5C6847P-1 performs these functions by reading the display memory in the order of the CRT scan, adding the required synchronization signals such as luminance signal, color signal and then transferring the data stream serially to the RF modulator.

OPERATION

Address Outputs ($A_{12} \sim A_0$)

Thirteen address lines are used by the M5C6847P-1 to access the display memory (refresh memory). The starting address of the display memory is located at the upper-left corner of the display screen. As the television sweeps from the left to right and top to bottom, the VDG increments the RAM display address. The address lines are TTL-compatible and may be forced in a high-impedance state when input \overline{MS} goes low.

Data Input ($D_7 \sim D_0$)

Eight TTL-compatible data lines are used to input data from the display memory to be processed by the M5C6847P-1. The data is interpreted and transformed into video analog level signals.

Video Output (Y, ϕ_A, ϕ_B, CHB)

These video outputs are used to transfer luminance and color information of pictures displayed on television with standard NTSC systems. These outputs can be directly connected to the RF modulator M51342P.

Luminance Output (Y)

The luminance output is a 6-level analog output. The six level analog outputs contain composite, blank, and four levels of video intensity.

Chrominance Output (ϕ_A)

The chrominance output ϕ_A is a 3-level analog output. The signal is used in combination with ϕ_B and Y to specify one of eight colors.

Chrominance Output (ϕ_B)

The chrominance output ϕ_B is a 4-level analog output. These levels of the signal are used in combination with ϕ_A and Y to specify one of eight colors. The other level is used to specify the time of the color burst reference signal.

Chroma Bias Output (CHB)

The chroma bias output is a single level analog output that provides the DC reference for chrominance outputs.

Synchronization Input (\overline{MS}, CLK)

Memory Select Input (\overline{MS})

This is a TTL compatible input. When it goes low-level, address outputs ($A_{12} \sim A_0$) are forced in high-impedance state. When other devices such as the CPU access the display memory, it must be kept at low-level to prevent interference.

Clock input (CLK)

The clock input requires a 3.579545 MHz clock with a duty cycle of 50±5%. The M51342P RF modulator may

be used to supply the 3.579545 MHz clock.

Synchronization output ($\overline{FS}, \overline{HS}, \overline{RP}$)

The synchronization outputs \overline{FS} , \overline{HS} and \overline{RP} are TTL-compatible and provide circuits, exterior to the M5C6847P-1 states.

VIDEO DISPLAY GENERATOR

Field synchronization output (\overline{FS})

The high to low transition of the \overline{FS} output coincides with the end of active display area. The low to high transition of \overline{FS} coincides with the trailing edge of the vertical synchronization pulse. The CPU should not access display memory while \overline{FS} is at low-level to avoid undesired flicker on the screen.

Horizontal synchronization output (\overline{HS})

This signal is used for horizontal synchronization on the CRT. A fall from high-level to low-level indicates the leading edge of the horizontal synchronization signal.

Row preset output (\overline{RP})

This signal can be used when an external character generator ROM that is used with the VDG. An external 4-bit binary counter must also be added to supply row selection.

The counter is clocked by the \overline{HS} signal and cleared by the \overline{RP} signal. See Table 4 ② for details.

Mode Control Inputs ($\overline{A/G}$, $\overline{A/S}$, $\overline{INT/EXT}$, GM_2 , GM_1 , GM_0 , CSS and INV)

These eight TTL-compatible input signals are used to determine and control the operational modes of the M5C6847P-1. Outline and details of the operational modes are shown in Table 1~3.

Alphanumeric mode

A screen in the alphanumeric mode is composed of 32 characters x 16 lines. Each character occupies space equivalent to an 8 x 12 dot matrix. The internal character generator can generate 64 characters (6-bit ASCII). Each character is formed by a 5 x 7 dot matrix. The low-order 6 bits of the 8-bit data input are used to select 1 of 64 characters and the remaining 2 bits can be used to implement the CSS and INV signal inputs. Operation in this mode requires a display memory of at least 512 bytes.

Semigraphic 4 mode

A screen in the semigraphics 4 mode is composed of 64 x 32 display elements. A display element is a 4 x 6 dot matrix; that is to say, each 8 x 12 character dot matrix is split into 4 display elements, each display element being a 4 x 6 dot matrix. The low-order 4 bits of the 8-bit data input correspond to the 4 display elements of a character. Three data bits of the remaining 4 bits may be used to select one of eight colors for the entire character box. The extra bit is available to switch the operation mode. Operation in this mode requires a display memory of at least 512 bytes.

Semigraphics 6 mode

A screen in the semigraphics 6 mode is composed of 64 x 48 display elements. A display element is a 4 x 4 dot matrix; that is to say, each 8 x 12 character dot matrix is split into 6 display elements, each display element being a 4 x 4 dot matrix. The low-order 6 bits of the 8-bit data input to the 6 display elements of a character and the remaining 2 bits are used to determine color. Operation in this mode re-

quires a display memory of at least 512 bytes.

Full Graphic Modes

There are 8 full graphic modes. The border color (green or white) is selected by the level of the CSS signal. The CSS pin selects one of two sets of four colors in the four color graphic modes.

Color Graphic Mode 64 x 64

A screen in the 64 x 64 color graphic mode is composed of 64 x 64 display elements. Each display element can be 1 of 4 colors. Operation in this mode requires a display memory of at least 1024 bytes.

Graphic mode 128 x 64

A screen in the 128 x 64 graphic mode is composed of 128 x 64 display elements. Each display element can be green or white depending on the level of the CSS signal. Operation in this mode requires a display memory of at least 1024 bytes.

Color graphic mode 128 x 64

A screen in the 128 x 64 color graphic mode is composed of 128 x 64 display elements. Each display element can be 1 of 4 colors. Operation in this mode requires a display memory of at least 2048 bytes.

Graphic mode 128 x 96

A screen in the 128 x 96 graphic mode is composed of 128 x 96 picture elements. Each display element can be green or white depending on the level of the CSS signal. Operation in this mode requires a display memory of at least 2048 bytes.

Color graphic mode 128 x 96

A screen in the 128 x 96 color graphic mode is composed of 128 x 96 display elements. Each display element can be 1 of 4 colors. Operation in this mode requires a display memory of at least 3072 bytes.

Graphic mode 128 x 192

A screen in the 128 x 192 graphic mode is composed of 128 x 192 display elements. Each display element can be green or white depending on the level of the CSS signal. Operation in this mode requires a display memory of at least 3072 bytes.

Color graphic mode 128 x 192

A screen in the 128 x 192 color graphic mode is composed of 128 x 192 display elements. Each picture element can be 1 of 4 colors. Operation in this mode requires a display memory of at least 6144 bytes.

Graphic mode 256 x 192

A screen in the 256 x 192 graphic mode is composed of 256 x 192 display elements. Each display element can be green or white depending on the level of the CSS signal. Operation in this mode requires a display memory of at least 6144 bytes.

Details of the 8 graphic modes are shown in Table 4 which gives more information in an easy to understand form.

Table 4 Operational characteristics in the various graphic modes

VIDEO DISPLAY GENERATOR

Internal Character Generator

The M5C6847P-1 generates the 64 standard ASCII characters in a 5 x 7 dot matrix form. It generates the 64 standard ASCII characters according to a 6-bit code. The code for each character is showed in Table 5.

Table 5 M5C6847P-1 character set

EXAMPLE OF DISPLAY ON CRT

The M5C6847P-1 can be used to generate characters for display on a video screen. An example of a display is shown in Fig. 1.

Fig. 1 Example of a display by a M5C6847P-1

APPLICATION EXAMPLE

One example of interfacing a M5C6847P-1 with a television set for home use is shown in Fig. 2. A M5L8085AP is used as the CPU in the example shown. The CPU executes the programs to control display and write the information for one screen into display memory. The M5C6847P-1 performs the main functions of interfacing with the CRT such as synchronizing scan, reading the display information from the display memory while adding necessary synchronization signals and sending to the RF modulator.

8

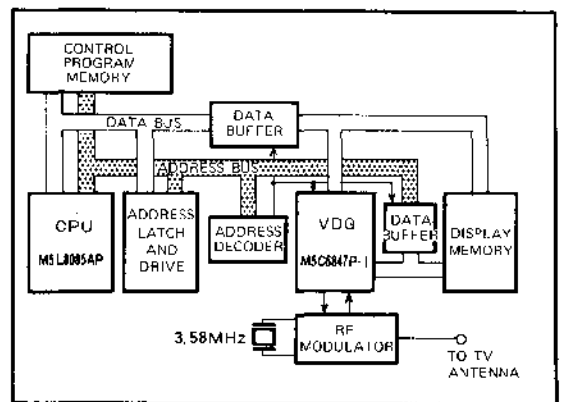

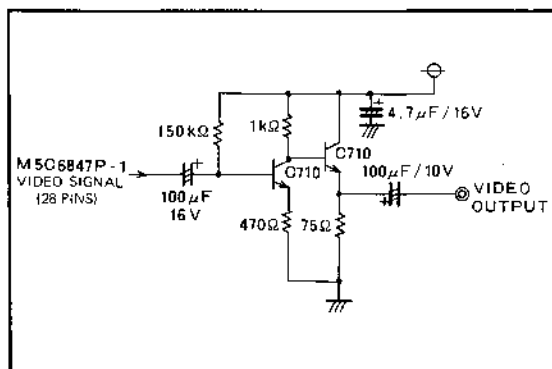

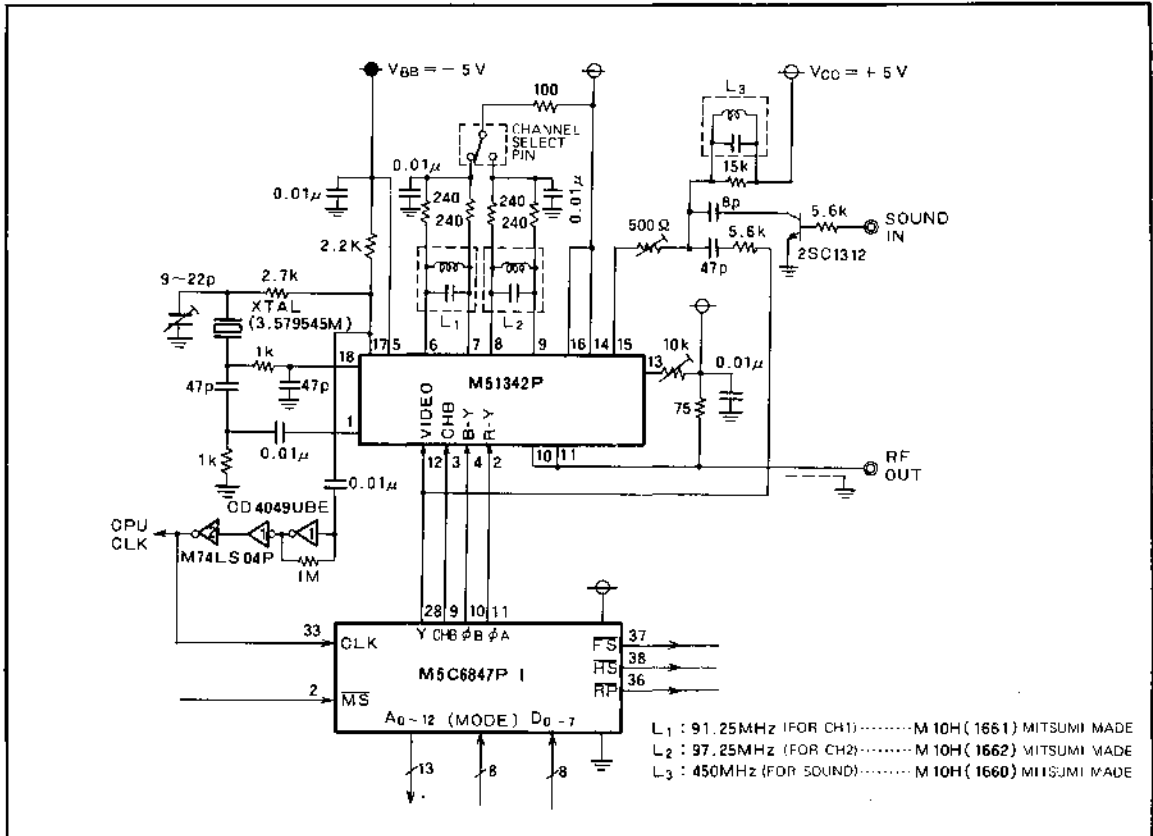

Fig. 2 Application example using the M5C6847P-1

VIDEO DISPLAY GENERATOR

A schematic for using the M5C6847P-1 with the M51342P RF modulator is shown in Fig. 3. M51342 requires $\pm 5V$ power supplies. The video signal and chroma signal from the M5C6847P-1 can be modulated with the sound signal to form a RF signal that appears the same as the television antenna input signal. The video amp circuit to

enable direct connection to a M5C6847P-1 is shown in Fig. 4. This can be connected to the monochrome video monitor. In this case, the impedance is 75Ω .

Four levels of brightness (black, low, medium and high) can display a clear picture.

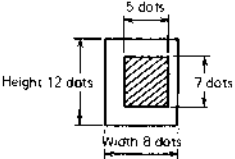

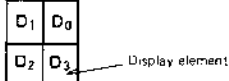

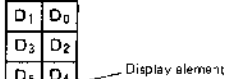

VIDEO DISPLAY GENERATOR

Data and Display Relation

The relation between data and 5 display modes is shown in Table 6.

MITSUBISHI LSIs M5L 8041A-XXXP

UNIVERSAL PERIPHERAL INTERFACE

DESCRIPTION

The M5L8041A-XXXP is a general-purpose, programmable interface device designed for use with a variety of 8-bit microcomputer systems. This device is fabricated using N-channel silicon-gate ED-MOS technology.

FEATURES

- Mask ROM:1024-word by 8-bit
- Static RAM: 64-word by 8-bit
- 18 programmable I/O pins
- Asynchronous data register for interface to master processor
- 8-bit CPU, ROM, RAM, I/O, timer, clock and low power standby mode
- Single 5V supply
- Alternative to custom LSI
- Interchangeable with Intel's 8041A in function, electrical characteristics and pin configuration

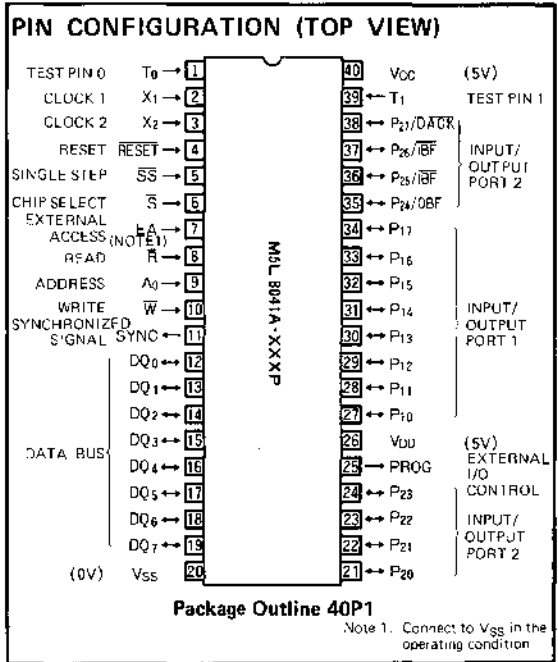

APPLICATION

- Alternative to custom LSI for peripheral interface

FUNCTION

The M5L8041A-XXXP contains a small stand-alone micro-computer.

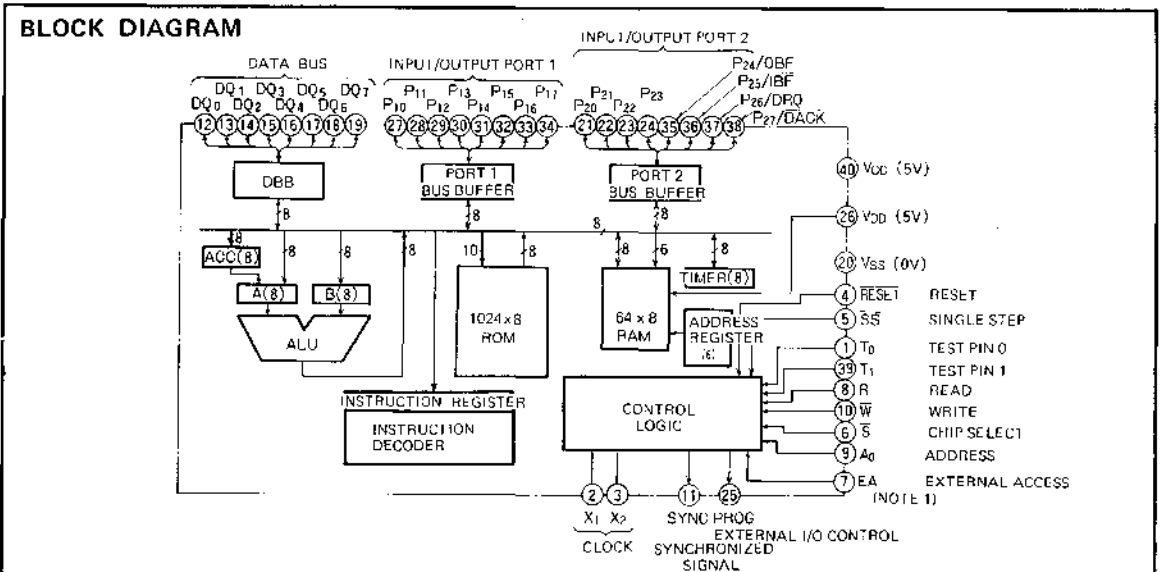

When it is used as a peripheral controller, it is called the slave computer in contrast to the master processor. These two devices can transfer the data alternatively through the buffer register between them. The M5L8041A-XXXP contains the buffer register to use this LSI as a slave computer, and can be accessed the same as other standard peripheral

devices. Because M5L8041A-XXXP is a complete micro-computer, it is easy to develop a user-oriented mask-programmed peripheral LSI only by changing control software.

BLOCK DIAGRAM

UNIVERSAL PERIPHERAL INTERFACE

PIN DESCRIPTION

Pin	Name	Input or output	Function
V _{SS}	Ground	—	Connected to a 0V supply (ground)
V _{CC}	Main power supply	—	Connected to a 5V supply
V _{DD}	Power supply	—	1 Connected to a 5V supply 2 Used as a memory hold supply when V _{CC} is cut off
PROG	Program	Out	Serves as the strobe signal when an M5L8243P I/O expander is used
P ₁₀ ~P ₁₇	Port 1	In/out	Quasi-bidirectional port. When used as an input port, FF ₁₆ must first be output to this port. After resetting, however, when not used afterwards as an output port, this is not necessary.
P ₂₀ ~P ₂₇	Port 2	In/out	1 The same as port 1 2 P ₂₀ ~P ₂₃ are used when an M5L8243P I/O port expander is used
DQ ₀ ~DQ ₇	Data bus	In/out	Serves as a sync signal for read and write operations to and from the bidirectional bus. Data remains latched.
T ₀	Test pin 0	In	Provides external control of conditional program jumps (JTO/JNTO instructions).
T ₁	Test pin 1	In	1 Provides external control of conditional program jumps (JT1/INT1 instructions). 2 Can serve as the input pin for the event counter (STRT CNT instructions).
\bar{S}	Chip select input	In	Chip select input for data bus control
\bar{R}	Read enable signal	In	Serves as the read signal when the master CPU is accepting data on the data bus from the M5L8041A-XXXP
\bar{W}	Write enable signal	In	Serves as the write signal when the master CPU is outputting data from the bus to the M5L8041A-XXXP
RESET	Reset	In	CPU initialization input
SYNC	Sync signal output	Out	Output 1 time for each machine cycle
A ₀	Address input	In	An address input used to indicate whether the signal on the data bus is data or a command
\bar{SS}	Single step	In	Used to halt the execution of a command by the CPU. When used in combination with the SYNC signal, the command execution of the CPU can be halted every instruction to enable single step operation.
EA	External access	In	Normally maintained at 0V
X ₁ , X ₂	Crystal inputs	In	An internal clock circuit is provided so that by connecting an RC circuit or crystal to these input pins the clock frequency can be determined. Pins X ₁ and X ₂ can also be used to input an external clock signal.

UNIVERSAL PERIPHERAL INTERFACE

BASIC FUNCTION BLOCKS

Program Memory (ROM)

The M5L8041A-XXXP contains 1024 bytes of ROM. The program for the users application is stored in this ROM. Addresses 0, 3, 7 of the ROM are reserved for special functions. Table 1 shows the meaning and function of these three special addresses.

Table 1 Reserved, defined addresses and their meanings and functions

Address	Meaning and function
0	The first instruction executed after a system reset.
3	The first instruction executed after an external interrupt is accepted.
7	The first instruction executed after a timer interrupt is accepted.

The ROM can be used to store constants and other 8-bit fixed data in addition to the program. Instructions such as MOVPA, @A and MOVPA, @A can be used to access the constants and data. The data could be in the form of tables, and can be easily looked up.

Data Memory (RAM)

The M5L8041A-XXXP contains 64 bytes of RAM. The RAM is used for data storage and manipulation and is divided into sections for more efficient processing. Addresses 0~7 and 24~31 form two banks of general purpose registers that can be directly addressed. Addresses 0~7 compose bank 0 and are numbered R₀~R₇. Addresses 24~31 compose bank 1 and are also numbered R₀~R₇. Only one bank is active at a time. The instructions SEL RB0 and SEL RB1 are used to select the working bank. Fig. 1 shows the division of the RAM and its mapping.

The remaining section, addresses 32 and above, must be accessed indirectly using the general-purpose registers R₀ or R₁. Of course all addresses can be indirectly addressed using the general-purpose registers R₀ and R₁.

A good practice to simplify programming is to reserve general-purpose register bank 0 for use of the main program and register bank 1 for interrupt programs. For example if register bank 0 (addressed 0~7) is reserved for processing data by the main program, when an interrupt is accepted the first instruction would be to switch the working registers from bank 0 to bank 1. This would save the data of the main program (addresses 0~7). The interrupt program can then freely use register bank 1 (addresses 24~31) without destroying or altering data of the main program. When the interrupt processing is complete and control is returned to the main program by the RETR instruction, register bank 0 (in this example) is automatically restored as the working register bank at the same time the main program counter is restored.

Addresses 8~23 compose an 8-level program counter stack. The details for using the stack will be found in the "Program Counter and Stack" section. Please refer to that section for details.

Address 0~31 have special functions, but when not all of the registers are required, the ones not needed can be used for general storage. This includes both banks of general-purpose registers and the stack.

Fig. 1 Data memory (RAM)

UNIVERSAL PERIPHERAL INTERFACE

Program Counter (PC) and Stack (SK)

The MSL8041A-XXXP program counter is a 10-bit counter configured as shown in Fig. 2.

When an interrupt or a subroutine call has occurred, the program currently being executed is interrupted and the execution flow must transfer to the interrupt program or subroutine. When such a condition has been encountered, the value currently stored in the program counter must be saved for use when restarting execution of the original program flow. The storage provided for this saving operation is the program counter stack. The program stack counter is used to store not only the program counter value but simultaneously store 4 bits of the PSW (Program Stack Word). The program counter stack uses addressed 8~23 of RAM. Ten bits are required to store the program counter value while 4 bits are required for the PSW. Therefore, each save operation uses 2 bytes (16 bits) of RAM. Thus, using RAM addresses 8~23, 8 levels of program counter value and PSW can be stored on the program stack. This storage scheme is shown in Fig. 3. To store which program counter stack location has last been entered, a 3-bit stack pointer is used. This stack pointer is also part of the PSW. However, the stack pointer itself is not stored in the program counter stack. The stack pointer is automatically incremented by 1 every time the program counter value and PSW are stored on the program stack. In the reverse operation in which these values are read from the program stack, the program stack pointer is decremented by 1. Note that the program counter stack always indicates the next storage location for the program counter value. Therefore, when return is made from a subroutine (using RET or RETR), the stack pointer is first decremented by 1, after which the contents of the program stack at the location indicated by the stack pointer are transferred to the program counter.

Fig. 2 Program counter

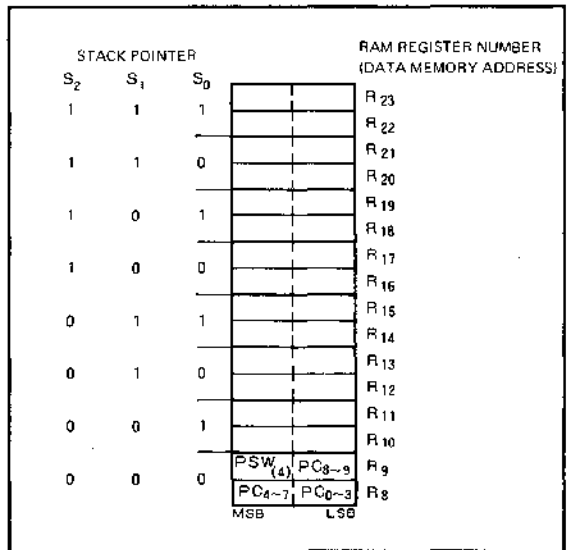

Fig. 3 Relation between the program counter stack and the stack pointer

UNIVERSAL PERIPHERAL INTERFACE

PROGRAM STATUS WORD (PSW)

The PSW (program status word) is stored in 8 bits of register storage. The configuration of the PSW is shown in Fig. 4. The high-order 4 bits of the PSW are stored in the stack, along with the PC, when an interrupt is accepted or a subroutine call executed. When control is returned to the main program by RETR both the PC and the high-order 4 bits of PSW are restored. When control is returned by RET only the PC is restored, so care must be taken to assure that the contents of the PSW was not unintentionally changed.

The order and meaning of the 8 bits of the PSW are shown below.

- Bit 0~2: Stack pointer (S_0, S_1, S_2)
- Bit 3: Unused (always 1)
- Bit 4: Working register bank indicator
0 = Bank 0 1 = Bank 1
- Bit 5: Flag 0 (F_0) (value is set by the user and can be tested)
This value can be checked by JFO.
- Bit 6: Auxiliary carry (AC) (it is set/reset by instructions ADD and ADC and used by instruction DA A).
- Bit 7: Carry bit (C) (indicates an overflow after execution)

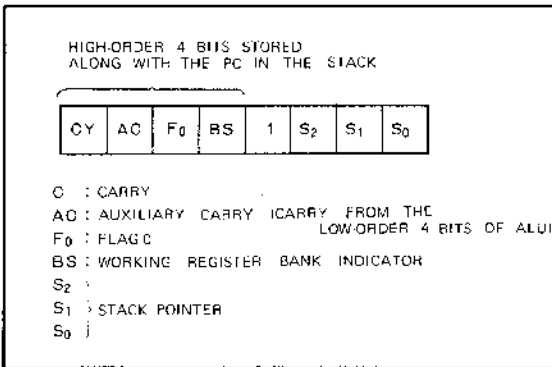

Fig. 4 Program status word

I/O PORTS

The M5L8041-XXXP has two 8-bit ports, which are called data bus, port 1 and port 2.

Port 1 and Port 2

Ports 1 and 2 are both 8-bit ports with identical properties. The output data of these ports are retained and do not change until another output is loaded into them. When used as inputs the input data is not retained so the input signals must be maintained until an input instruction is executed and completed.

Ports 1 and 2 so-called quasi-bidirectional ports have a special circuit configuration to accomplish this. The special circuit is shown in Fig. 5. All pin of ports 1 and 2 can be used for input or output.

Internal on chip pull-up resistors are provided for all the ports. Through the use of approximately 50kΩ pull-up

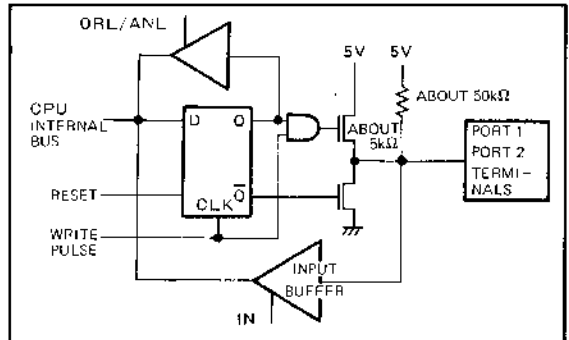

Fig. 5 I/O ports 1 and 2 circuit

resistors, TTL standard high-level or low-level signals can be supplied. Therefore each pin can be used for both input and output. To shorten switching time from low-level to high-level, when 1s are output, a device of about 5kΩ or lower is inserted for a short time (about 500ns when using a 6MHz crystal oscillator).

A port used for input must output all 1s before it reads the data from the input pin. After resetting, a port is set to an input port and remains in this state, therefore it is not necessary to output all 1s if it is to be used for input. In short a port being used for output must output 1s before it can be used for input.

The individual pins of quasi-bidirectional ports can be used for input or output. Therefore some pins can be in the input mode while the remaining pins of a port are in the output mode. This capability of ports 1 and 2 is convenient for inputting or outputting 1-bit or data with few bits. The logical instructions ANL and ORL can easily be used to manipulate the input or output of these ports.

UNIVERSAL PERIPHERAL INTERFACE

(2) Data Bus

The data bus ($DQ_0 \sim DQ_7$) is used for accepting data, commands, and statuses, between the master CPU and the M5L8041A-XXXP. The data bus is controlled by the following 4 control signals, the relationship between the control signals and the data bus being shown in table 2.

A_0 : Address input indicating data/command, bus buffer register and status, and register

\bar{R} : Read input

\bar{W} : Write input

\bar{S} : Chip select input

Table 2 Control Signals and Data Bus Relationships

\bar{S}	\bar{R}	\bar{W}	A_0	Data bus status	Data bus data
0	0	1	0	Read	Data
0	0	1	1	Read	Status
0	1	0	0	Write	Data
0	1	0	1	Write	Command (F1-1)
1	X	X	X	High impedance	—

Fig. 6 shows the internal structure of the data bus. The 3 registers' (status register, output data bus buffer register, and input data/command bus buffer register) functions are described below.

Fig. 6 Data bus internal structure

• Status Registers

The status registers consist of 8-bit registers, the upper 4 bits of which ($ST_4 \sim ST_7$) being arbitrarily settable by software (MOVSTS, A instruction). The lower 4 bits (OBF, IBF, F_0 , F_1) being set as follows.

OBF (Output Buffer Full)

The OBF flag is automatically set to 1 when the M5L8041A-XXXP internally executes an output instruction (OUT DDB, A), upon which the master CPU reads the contents of the output data bus buffer and clears this flag.

IBF (Input Buffer Full)

The IBF flag is set to 1 when the master CPU causes the writing of data or a command into the input data/command bus buffer, whereupon the input instruction (IN A DDB) is executed by the M5L8041A-XXXP and this flag is subsequently cleared.

F_0 (Flag 0)

The F_0 flag is set by the flag setting instructions (CPL F_0 , CLR F_0) to inform the master CPU of the M5L8041A-XXXP internal status.

F_1 (Flag 1)

The F_1 flag is set when data or commands are input to the input data/command bus buffer by the master CPU to indicate the A_0 status.

UNIVERSAL PERIPHERAL INTERFACE

The F_1 flag may also be set by the flag setting instructions (CPL F_1 , CLR F_1).

● Output Data Bus Buffer (DBB {0}) Register

The output data bus buffer (DBB {0}) register is loaded with the contents of accumulator (A) by means of the OUT DBB, A instruction. Since the OBF flag is set at this time, the master CPU checks the status of this OBF flag to ascertain whether data has been transferred to the DBB {0} register.

● Input Data/Command Bus Buffer (DBB {1}) Register

When the master CPU has generated a write request ($\overline{W}=0$), the data on the data bus is transferred to the DBB {1} register. At this time, because the IBF flag is set, the status of the IBF flag is checked internally by the M5L8041A-XXXP to ascertain whether or not data or commands have been transferred.

CONDITIONAL JUMPS USING PINS T_0 , T_1 and FLAGS IBF, OBF

Conditional jump instructions are used to alter program depending on internal and external conditions (states). Details of the jump instructions can be found in the section on machine instructions.

The input signal status of T_0 , T_1 , and flags IBF and OBF can be checked by the conditional jump instructions. These input pins, through conditional jump instructions such as JTO and JNT0, can be used to control a program. Programs and processing time can be reduced by being able to test data in input pin rather than reading the data register and then testing it in the register.

Pin T_1 has other functions and uses that are not related to conditional jump instructions. The details of these other functions and uses can be found in the section on pin functions.

INTERRUPT

When an external interrupt is encountered by the CPU, the \overline{S} and \overline{W} pins are made low. The IBF flag is used to provide recognition of this interrupt condition.

Sampling of interrupt requests is done each machine cycle during the output of the SYNC signal. When an interrupt request is recognized, upon the completion of execution of the present instruction, a subroutine jump is made to address 3 of program memory. Just as would be the case in a normal subroutine jump, the program counter and program status word are saved on the program stack.

The program memory address 3 is normally used to store an unconditional jump to the address at which is stored the interrupt processing program.

The interrupt level is one, so the next interrupt cannot be accepted until the current interrupt processing has been completed. The RETR instruction terminates the interrupt processing. That is to say, the next interrupt can not be accepted until the RETR instruction is executed. The next interrupt can be accepted at the start of the second cycle of the RETR instruction (2-cycle instruction). Time/event counter overflow which causes an interrupt request also will not be accepted.

After the processing for an interrupt is completed control is returned to the main program. This is accomplished by executing RETR which restores the program counter and PSW automatical and checks \overline{INT} and the time/event counter overflow for an interrupt request. If there is an interrupt request, the control will not be returned to the main program but will be transferred to the interrupt handling program.

An external interrupt has a higher priority than a timer interrupt. This means that, if an external and timer interrupt request are generated at the same time, the external interrupt has the priority and will be accepted first.

When a second level of external interrupt is required, the timer interrupt, if not being used, can provide this. The procedure for this is to first enable the timer interrupt, set the timer/event counter to FF_{16} and put the CPU in the event counter mode. After this has been done, if T_1 input is changed to low-level from high-level, an interrupt is generated in address 7.

Flag IBF can also be tested using a conditional jump instruction. For more details on this procedure, check the "Conditional Jumps Using pins T_0 , T_1 and Flags IBF, OBF" section.

UNIVERSAL PERIPHERAL INTERFACE

TIMER/EVENT COUNTER

The timer/event counter for the M5L8041A-XXXP is an 8-bit counter, that is, used to measure time delays or count external events but not both. The same counter is used to measure time delays or count external events by simply changing the input to the counter.

The counter can be preset by executing an MOV T, A instruction. The value of the counter can be read for checking by executing an MOV A, T instruction. Reset will stop the counting but the counter is not cleared, so counting can be resumed.

The largest number the counter can contain is FF₁₆. If it is incremented by 1 when it contains FF₁₆, the counter will be reset to 0, the overflow flag is set and a timer interrupt request is generated.

The conditional jump instruction JTF can be used to test the overflow flag. Care must be used in executing the JTF instruction because the overflow flag is cleared when executed (reset). When a timer interrupt is accepted, the control is transferred to address 7 of program memory.

When both a timer and external interrupt request are generated at the same time, the external interrupt is given priority and will be accepted first by automatically subroutine jumping to address 3 of program memory. The timer interrupt request is kept and will be processed when the external interrupt has been completed and a RETR is executed. A latched timer interrupt request is cancelled when a timer interrupt request is generated.

The START CNT instruction is used to change the counter to an event counter. Then Pin T₁ signal becomes the input to the event counter and an event is counted each full cycle (low-high-low one event). The maximum rate that can be counted is one time in 3 machine cycles (7.5μs when using 6MHz crystal). The high-level at T₁ must be maintained at least 1/5 of the cycle time (500ns when using 6MHz crystal).

The START T instruction is used to change the counter to a timer. The internal clock signal becomes the input to the timer. The internal clock is 1/32 of 400kHz (when using 6MHz crystal) or 12.5kHz. The timer is therefore counted up every 80μs. Fig. 7 shows the timer/event counter.

The counter can be preset by executing an MOV T, A instruction. The timer can be used to measure 80μs~20ms in multiples of 80μs. When it is necessary to measure over 20ms (maximum count 256x80μs) of delay time the number of overflows, one every 20ms, can be counted by the program. To measure times of less than 80μs; external clock pulses can be input through T₁ while the counter is in the event counter mode. Every third (or more) ALE signal can be used instead of an external clock pulses.

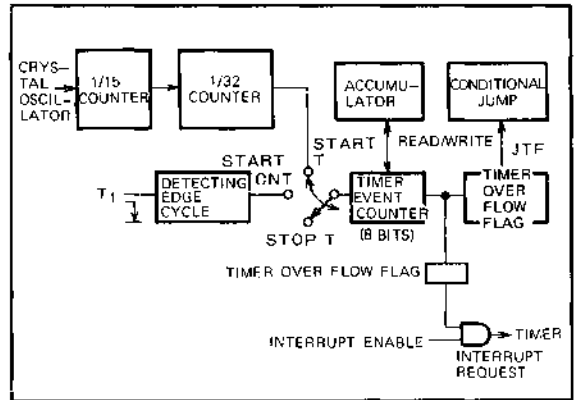

Fig. 7 Timer/event counter

UNIVERSAL PERIPHERAL INTERFACE

CYCLE TIMING

The output of the state counter is 1/3 the input frequency from the oscillator. A CLK signal is generated every 500ns (one state cycle) which is used for the demarcation of each machine state.

Fig 9 shows the relationship between clock and generated cycles.

One machine cycle contains 5 states with a CLK signal for demarcation of each state. The M5L8041A-XXXP instructions are executed in one machine cycle or two machine cycles. An instruction cycle can be one or two machine cycles as shown in Fig. 10.

Fig. 8 Clocking cycle generation

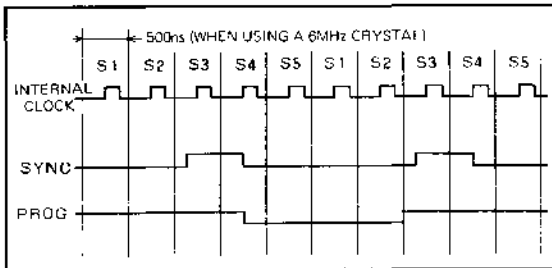

Fig. 9 Clock and generated cycle signals

Fig. 10 Instruction execution timing

RESET

The reset pin is for resetting the CPU. A Schmitt trigger circuit along with a pull-up register are connected to it on the chip. A reset can easily be generated by attaching a 1µF as capacitor as shown in Fig. 11. An external reset pulse applied at $\overline{\text{RESET}}$ must remain at low-level for at least 10ms after power has been turned on and reached its normal level.

The reset function causes the following initialization within the CPU.

1. Program counter is reset to 0.
2. Stack pointer is reset to 0.
3. Memory bank is reset to 0.
4. Ports 1 and 2 are reset to input mode.
5. External and timer interrupts are reset to disable state.
6. Timer is stopped.
7. Timer overflow flag is cleared.
8. Flags F_0 and F_1 are cleared.

Fig. 11 Example of a reset circuit

8

UNIVERSAL PERIPHERAL INTERFACE

SINGLE-STEP OPERATION

The pin \overline{SS} on the M5L8041A-XXXP is provided to facilitate single-step operation. In single-step operation, the CPU stops after the execution of each instruction is completed and the memory address (12 bits) of the next instruction to be fetched is output through the data bus (8 bits) plus the low-order 4 bits of port 2. The user can use this to trace the flow of this program instruction by instruction and will find this an aid in program debugging. Single-step operation is controlled through \overline{SS} and SYNC as shown in Fig. 12.

Fig. 12. Single-step operation circuit and timing

A type D flip-flop with preset and reset pins, as shown in Fig. 12, is used to generate the signal for \overline{SS} . When the preset pin goes to low-level, \overline{SS} goes to high-level, which puts the CPU in RUN mode. When the preset pin is grounded it goes to high-level. Then \overline{SS} goes to low-level. When \overline{SS} goes to low-level, the CPU stops. Then when the push-button switch is pushed, a pulse is sent to the clock pin of the type D flip-flop which turns \overline{SS} to high-level. When \overline{SS} goes to high-level the CPU fetches the next instruction and begins to execute it, but then an ALE signal is sent to the reset pin of the type D flip-flop which turns \overline{SS} to low-level. The CPU again stops as soon as execution of the current instruction is completed. The CPU is in single-step operation as shown in Fig. 13.

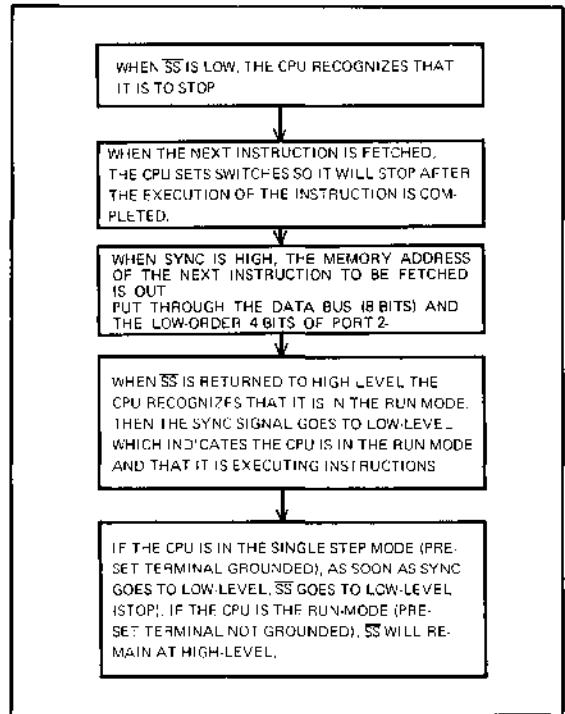

Fig. 13 CPU operation in single-step mode

UNIVERSAL PERIPHERAL INTERFACE

Central Processing Unit (CPU)

Central Processing Unit (CPU) is composed of an 8-bit parallel arithmetic unit, accumulator, flag flip-flop and instruction decoder. The 8-bit parallel arithmetic unit has circuitry to perform the four basic arithmetic operations (plus, minus, multiply and divide) as well as logical operations such as AND and OR. The flag flip-flop is used to indicate status such as carry and zero. The accumulator contains one of the operations and the result is usually retained in the accumulator. (The flag flip-flops hold the carry and borrow states for execution of all processing instructions.)

DMA Control

In addition to use as a normal input/output port, the M5L8041A-XXXP port P₂₆ and P₂₇ can be used to provide control signals for handshake control of DMA operations. Immediately after resetting, P₂₆ and P₂₇ can be used as a normal port (Fig. 14).

Fig. 14 DMA Control

When the EN DMA instruction is executed, P₂₆ becomes the DRQ (DMA request) output. Subsequently, when P₂₆ is set to 1, DRQ becomes 1 and DMA data transfer is requested.

DRQ is returned to 0 when $\overline{DACK} \cdot \overline{R}$, $\overline{DACK} \cdot \overline{W}$, or EN DMA is executed.

In addition, when EN DMA is executed, P₂₇ becomes the \overline{DACK} (DMA acknowledgment) input. This \overline{DACK} input serves as the chip select input during DMA transfer operations. Therefore, the normal chip select \overline{S} status has no meaning during DMA transfers.

Interrupts of the Master CPU

In addition to use as a normal input/output port, the M5L8041A-XXXP P₂₄ and P₂₅ pins may be used as the IBF (Input Buffer Full) flag and OBF (Output Buffer Full) flag outputs. Immediately after resetting, P₂₄ and P₂₅ are usable as normal input ports.

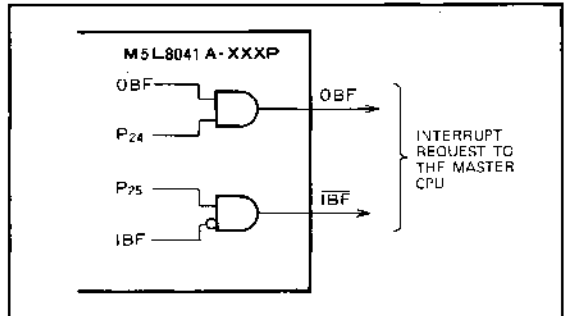

Fig. 15 Interrupt requests to the master CPU

When the EN FLAGS instruction is executed, P₂₄ becomes the OBF pin and P₂₅ the \overline{IBF} pin. At this time, in order to enable OBF flag and \overline{IBF} flag status outputs for pin 24 and pin 25, it is necessary to set pin 24 and pin 25 to 1. With P₂₄ and P₂₅ set to 0, these flag statuses are not output. The OBF flag output indicates that data is being output to the M5L8041A-XXXP output data bus buffer register while the \overline{IBF} flag output indicates that data can be accepted by the input data/command bus buffer register.

Transfer	MOV A, #n	0 0 1 0 0 0 1 1 n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	2 3 n	2	2	(A) ← n				Transfers data n to register A.
	MOV A, PSW	1 1 0 0 0 1 1 1	C 7	1	1	(A) ← (PSW)				Transfers the contents of the program status word to register A.
	MOV A, R _r	1 1 1 1 1 r ₂ r ₁ r ₀	F 0 r	1	1	(A) ← (R _r) r = 0 ~ 7				Transfers the contents of register R _r to register A.
	MOV A, @R _r	1 1 1 1 0 0 0 r ₀	F 0 r	1	1	(A) ← (M(R _r)) r = 0 ~ 1				Transfers the contents of memory location, of the current page, whose address is in register R _r to register A.
	MOV PSW, A	1 1 0 1 0 1 1 1	D 7	1	1	(PSW) ← (A) (C) ← (A ₇), (AC) ← (A ₆)	○	○		Transfers the contents of register A to the program status word.
	MOV STS, A	1 0 0 1 0 0 0 0	9 0	1	1	(STS) ← (A) (ST4 ~ ST7) ← (A ₄ ~ A ₇)			4	Transfers the contents of register A to the system status register.
	MOV R _r , A	1 0 1 0 1 r ₂ r ₁ r ₀	A 8 r	1	1	(R _r) ← (A) r = 0 ~ 7				Transfers the contents of register A to register R _r .
	MOV R _r , #n	1 0 1 1 1 r ₂ r ₁ r ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	B 8 r n	2	2	(R _r) ← n r = 0 ~ 7				Transfers data n to register R _r .
	MOV @R _r , A	1 0 1 0 0 0 0 r ₀	A 0 r	1	1	(M(R _r)) ← (A) r = 0 ~ 1				Transfers the contents of register A to memory location, of the current page, whose address is in register R _r .
	MOV @R _r , #n	1 0 1 1 0 0 0 r ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	B 0 r n	2	2	(M(R _r)) ← n r = 0 ~ 1				Transfers data n to memory location, of the current page, whose address is in register R _r .
	MOVP A, @A	1 0 1 0 0 0 1 1	A 3	1	2	(A) ← (M(A))				Transfers the data of memory location, of the current page, whose address is in register A to register A.
	MOVP3 A, @A	1 1 1 0 0 0 1 1	E 3	1	2	(A) ← (M(page 3, A))				Transfers the data of memory location, of page 3, whose address is in register A to register A.
	XCH A, R _r	0 0 1 0 1 r ₂ r ₁ r ₀	2 8 r	1	1	(A) ↔ (R _r) r = 0 ~ 7				Exchanges the contents of register R _r with the contents of register A.
XCH A, @R _r	0 0 1 0 0 0 0 r ₀	2 0 r	1	1	(A) ↔ (M(R _r)) r = 0 ~ 1				Exchanges the contents of memory location, of the current page, whose address is in register R _r with the contents of register A.	
XCHD A, @R _r	0 0 1 1 0 0 0 r ₀	3 0 r	1	1	(A ₀ ~ A ₃) ↔ (M(R _r) ₀ ~ R _r ₃) r = 0 ~ 1				Exchanges the contents of the low-order 4-bits of register A with the low-order 4-bits of memory location, of the current page, whose address is in register R _r .	
Arithmetic	ADD A, #n	0 0 0 0 0 0 1 1 n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	0 3 n	2	2	(A) ← (A) + n	○	○	1	Adds data n to the contents of register A and sets the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.
	ADD A, R _r	0 1 1 0 1 r ₂ r ₁ r ₀	6 8 r	1	1	(A) ← (A) + (R _r) r = 0 ~ 7	○	○	1	Adds the contents of register R _r to the contents of register A and sets the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.
	ADD A, @R _r	0 1 1 0 0 0 0 r ₀	6 0 r	1	1	(A) ← (A) + (M(R _r)) r = 0 ~ 1	○	○	1	Adds the contents of register A and the contents of memory location, of the current page, whose address is in register A and sets the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.
	ADDC A, #n	0 0 0 1 0 0 1 1 n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	1 3 n	2	2	(A) ← (A) + n + (C)	○	○	1	Adds the carry and data n to the contents of register A and sets the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.
	ADDC A, R _r	0 1 1 1 1 r ₂ r ₁ r ₀	7 8 r	1	1	(A) ← (A) + (R _r) + (C) r = 0 ~ 7	○	○	1	Adds the carry and the contents of register R _r to the contents of register A and set the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.
	ADDC A, @R _r	0 1 1 1 0 0 0 r ₀	7 0 r	1	1	(A) ← (A) + (M(R _r)) + (C) r = 0 ~ 1	○	○	1	Adds the carry and the contents of memory location, of the current page, whose address is in register A and sets the carry flags to 1 if there is an overflow otherwise resets the carry flags to 0. The result is stored in register A.

UNIVERSAL PERIPHERAL INTERFACE

Item Type	Mnemonic	Instruction code			Hexa decimal	Bytes	Cycles	Function	Effected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀						C	AC	MA	
Subroutine call	CALL m	m ₁₀ m ₉ m ₈ 1	0 1 0 0	14 + m ₆ m ₁₀	2	2	((SP) ← (PC) (PSW ₄ ← PSW ₇) (SP) ← (SP) + 1 (PC ₀₋₁₀) ← m (PC ₁₁) ← MRF				Calls subroutine from address m. The program counter and the 4 high-order bits of the PSW are stored in the address indicated by the stack pointer (SP). The SP is incremented by 1 and m is transferred to PC ₀₋₁₀ and the MRF is transferred to PC ₁₁ .	
	RET	1 0 0 0	0 0 1 1	83	1	2	(SP) ← (SP) - 1 (PC) ← ((SP))				The SP is decremented by 1. The program counter is restored to the saved setting in the stack indicated by the stack pointer. The PSW is not changed and interrupt disable is maintained.	
	RETR	1 0 0 1	0 0 1 1	93	1	2	(SP) ← (SP) - 1 (PC) (PSW ₄ ← PSW ₇) ← ((SP))				The SP is decremented by 1. The program counter and the 4 high-order bits of the PSW are restored with the saved data in the stack indicated by the stack pointer. The interrupt becomes enabled after the execution is completed.	
Input/Output	IN A, P _p	0 0 0 0	1 0 P ₁ P ₀	08 + p	1	2	(A) ← (P _p) p = 1 - 2				Loads the contents of P _p in register A.	
	OUTL P _p , A	0 0 1 1	1 0 P ₁ P ₀	38 + p	1	2	(P _p) ← (A) p = 1 - 2				Output latches the contents of register A to P _p .	
	ANL P _p , #n	1 0 0 1	1 0 P ₁ P ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	98 - p n	2	2	(P _p) ← (P _p) ∧ n p = 1 - 2				Logical ANDs the contents of P _p and data n. Outputs the result to P _p .	
	ORL P _p , #n	1 0 0 0	1 0 P ₁ P ₀ n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	88 - p n	2	2	(P _p) ← (P _p) ∨ n p = 1 - 2				Logical ORs the contents of P _p and data n. Outputs the result to P _p .	
	IN A, DBB	0 0 1 0	0 0 1 0	22	1	1	(A) ← (DBB)				Enters the contents of data bus buffer (DBB) in register A.	
	OUT DBB, A	0 0 0 0	0 0 1 0	02	1	1	(DBB) ← (A)				Outputs the contents of register A to data bus buffer (DBB). DBF is set.	
	MOVD A, P _p	0 0 0 0	1 1 P ₁ P ₀	0C + P ₁ P ₀	1	2	(A ₀ - A ₃) ← (P _{p0} - P _{p3}) (A ₄ - A ₇) ← 0 p = 4 - 7				Inputs the contents of P _p of 8243 to the low-order 4 bits of register A and inputs 0 to the high-order 4 bits of register A.	
MOVD P _p , A	0 0 1 1	1 1 P ₁ P ₀	3C + P ₁ P ₀	1	2	(P _{p0} - P _{p3}) ← (A ₀ - A ₃) p = 4 - 7				Outputs the low-order 4 bits of register A to P _p .		
ANLD P _p , A	1 0 0 1	1 1 P ₁ P ₀	9C - P ₁ P ₀	1	2	(P _{p0} - P _{p3}) ← (P _{p0} - P _{p3}) ∧ (A ₀ - A ₃) p = 4 - 7				Logical ANDs the 4 low-order bits of register A and the contents of P _p . P _p contains the result.		
ORLD P _p , A	1 0 0 0	1 1 P ₁ P ₀	8C + P ₁ P ₀	1	2	(P _{p0} - P _{p3}) ← (P _{p0} - P _{p3}) ∨ (A ₀ - A ₃) p = 4 - 7				Logical ORs the 4 low-order bits of register A and the contents of P _p . P _p contains the result.

Arithmetic	ANL A, #n	0 1 0 1	0 0 1 1	5 3	n	2	2	(A) ← (A) ∧ n				The logical product of the contents of register A and data n, is stored in register A.
	ANL A, Rr	0 1 0 1	1 r ₂ r ₁ r ₀	5 6	+ r	1	1	(A) ← (A) ∧ (Rr) r = 0 ~ 7				The logical product of the contents of register A and the contents of register R _r is stored in register A.
	ANL A, @Rr	0 1 0 1	0 0 0 r ₀	5 0	r	1	1	(A) ← (A) ∧ (M(Rr)) r = 0 ~ 1				The logical product of the contents of register A and the contents of memory location of the current page, whose address is in register R _r , is stored in register A.
	ORL A, #n	0 1 0 0	0 0 1 1	4 3	n	2	2	(A) ← (A) ∨ n				The logical sum of the contents of register A and data n, is stored in register A.
	ORL A, Rr	0 1 0 0	1 r ₂ r ₁ r ₀	4 6	+ r	1	1	(A) ← (A) ∨ (Rr) r = 0 ~ 7				The logical sum of the contents of register A and the contents of register R _r is stored in register A.
	ORL A, @Rr	0 1 0 0	0 0 0 r ₀	4 0	r	1	1	(A) ← (A) ∨ (M(Rr)) r = 0 ~ 1				The logical sum of the contents of register A and the contents of memory location of the current page, whose address is in register R _r , is stored in register A.
	XRL A, #n	1 1 0 1	0 0 1 1	D 3	n	2	2	(A) ← (A) ∨ n				The exclusive OR of the contents of register A and data n, is stored in register A.
	XRL A, Rr	1 1 0 1	1 r ₂ r ₁ r ₀	D 6	+ r	1	1	(A) ← (A) ∨ (Rr) r = 0 ~ 7				The exclusive OR of the contents of register A and the contents of register R _r is stored in register A.
	XRL A, @Rr	1 1 0 1	0 0 0 r ₀	D 0	r	1	1	(A) ← (A) ∨ (M(Rr)) r = 0 ~ 1				The exclusive OR of the contents of register A and the contents of memory location of the current page, whose address is in register R _r , is stored in register A.
	INC A	0 0 0 1	0 1 1 1	1 7		1	1	(A) ← (A) + 1				Increments the contents of register A by 1. The result is stored in register A, and the carries are unchanged.
	DEC A	0 0 0 0	0 1 1 1	0 7		1	1	(A) ← (A) - 1				Decrements the contents of register A by 1. The result is stored in register A, and the carries are unchanged.
	CLR A	0 0 1 0	0 1 1 1	2 7		1	1	(A) ← 0				Clears the contents of register A, resets to 0.
	CPL A	0 0 1 1	0 1 1 1	3 7		1	1	(A) ← (A̅)				Forms 1's complement of register A, and stores it in register A.
	DA A	0 1 0 1	0 1 1 1	5 7		1	1	(A) ← (A)	○	○	1	The contents of register A is converted to binary-coded decimal notation, and it is stored in register A. If the contents of register A are more than 99 the carry flags are set to 1; otherwise they are reset to 0.
	SWAP A	0 1 0 0	0 1 1 1	4 7		1	1	(A ₄ -A ₇) → (A ₀ -A ₃)				Exchanges the contents of bits 0~3 of register A with the contents of bits 4~7 of register A.
	RL A	1 1 1 0	0 1 1 1	E 7		1	1	(A _{n+1}) ← (A _n) (A ₀) ← (A ₇) n = 0 ~ 6				Shifts the contents of register A left one bit. A ₇ the MSB is rotated to A ₀ the LSB.
RLC A	1 1 1 1	0 1 1 1	F 7		1	1	(A _{n+1}) ← (A _n) (A ₀) ← (C) (C) ← (A ₇) n = 0 ~ 6	○			Shifts the contents of register A left one bit. A ₇ the MSB is shifted to the carry flag and the carry flag is shifted to A ₀ the LSB.	
RR A	0 1 1 1	0 1 1 1	7 7		1	1	(A _n) ← (A _{n-1}) (A ₇) ← (A ₀) n = 0 ~ 6				Shifts the contents of register A right one bit. A ₀ the LSB is rotated to A ₇ the MSB.	
RRC A	0 1 1 0	0 1 1 1	6 7		1	1	(A _n) ← (A _{n-1}) (A ₇) ← (C) (C) ← (A ₀) n = 0 ~ 6	○			Shifts the contents of register A right one bit. A ₀ the LSB is shifted to the carry flag and the carry flag is shifted to A ₇ the MSB.	
Register arithmetic	INC Rr	0 0 0 1	1 r ₂ r ₁ r ₀	1 8	+ r	1	1	(Rr) ← (Rr) + 1 r = 0 ~ 7				Increments the contents of register R _r by 1. The result is stored in register R _r , and the carries are unchanged.
	INC @Rr	0 0 0 1	0 0 0 r ₀	1 0	r	1	(M(Rr)) ← (M(Rr)) + 1 r = 0 ~ 1				Increments the contents of the memory location of the current page, whose address is in register R _r by 1. Register R _r uses bit 0 ~ 5.	
	DEC Rr	1 1 0 0	1 r ₂ r ₁ r ₀	C 8	+ r	1	1	(Rr) ← (Rr) - 1 r = 0 ~ 7				Decrements the contents of register R _r by 1. The result is stored in register R _r , and the carries are unchanged.

UNIVERSAL PERIPHERAL INTERFACE

Item Type	Mnemonic	Instruction code			Hexadecimal ma	Bytes	Cycles	Function	Effected carry			Description
		D ₇ D ₆ D ₅ D ₄	D ₃ D ₂ D ₁ D ₀						C	AC	NOIP	
Jump	JBB m	b ₇ b ₆ b ₅ 1	0 0 1 0	1 2 + b	2	2	{A _b } = 1 then (PC ₀ - PC ₇) - m {A _b } = 0 then (PC) - (PC) + 2 b ₇ b ₆ b ₅ = 0 ~ 7				Jumps to address m of the current page when bit b of register A is 1. Executes the next instruction when bit b of register A is 0.	
	JNBF m	1 1 0 1	0 1 1 0	D 6	2	2	(IBF) = 0 then (PC ₀ - PC ₇) - m				Jumps to address m of the current page when IBF is 0, otherwise the next instruction is executed.	
	JOBF m	1 0 0 0	0 1 1 0	8 6 m	2	2	(OBF) = 1 then (PC ₀ - PC ₇) - m				Jumps to address m of the current page when OBF is 0, otherwise the next instruction is executed.	
	JTF m	0 0 0 1	0 1 1 0	1 6 m	2	2	(TF) = 1 then (PC ₀ - PC ₇) - m (TF) = 0 then (PC) - (PC) - Z				Jumps to address m of the current page when the overflow flag of the timer is 1, otherwise the next instruction is executed. Flag is cleared after executing.	
	JMP m	m ₁₀ m ₉ m ₈ 0	0 1 0 0	0 4 + m ₆ ~ 10 m	2	2	(PC ₃ - PC ₁₀) + m ₈ - m ₁₀ (PC ₀ - PC ₇) + m ₆ - m ₇ (PC ₁₁) + (MBF)				Jumps to address m on page m ₁₀ m ₉ m ₈ in the memory bank indicated by MBF.	
	JMPP #A	1 0 1 1	0 0 1 1	E 3	1	2	(PC ₀ - PC ₇) + (M(A))				Jumps to the memory location of the current page, whose address is in register A. But when the instruction executed was in address 255, jumps to next page.	
	DJNZ Rr, m	1 1 1 0	1 r ₂ r ₁ r ₀	E 0 + r	2	2	(Rr) - (Rr) - 1 r = 0 ~ 7 (Rr) + 0 then (PC ₀ - PC ₇) + m (Rr) = 0 then (PC) - (PC) + 2				Decrements the contents of register Rr by 1. Jumps to address m of the current page when the result is not 0, otherwise the next instruction is executed.	
	JC m	1 1 1 1	0 1 1 0	F 6 m	2	2	(C) = 1 then (PC ₀ - PC ₇) + m (C) = 0 then (PC) - (PC) - 2				Jumps to address m of the current page if the carry flag C is 1, otherwise the next instruction is executed.	
	JNC m	1 1 1 0	0 1 1 0	E 6 m	2	2	(C) = 0 then (PC ₀ - PC ₇) + m (C) = 1 then (PC) - (PC) + 2				Jumps to address m of the current page if the carry flag C is 0, otherwise the next instruction is executed.	
	JZ m	1 1 0 0	0 1 1 0	C 6 m	2	2	(A) = 0 then (PC ₀ - PC ₇) - m (A) + 0 then (PC) - (PC) + 2				Jumps to address m of the current page when the contents of register A are 0, otherwise the next instruction is executed.	
	JNZ m	1 0 0 1	0 1 1 0	9 6 m	2	2	(A) + 0 then (PC ₀ - PC ₇) + m (A) = 0 then (PC) - (PC) + 2				Jumps to address m of the current page when the contents of register A are not 0, otherwise the next instruction is executed.	
	JTO m	0 0 1 1	0 1 1 0	3 6 m	2	2	(T ₀) = 1 then (PC ₀ - PC ₇) + m (T ₀) = 0 then (PC) - (PC) + 2				Jumps to address m of the current page when flag T ₀ is 1, otherwise the next instruction is executed.	
	JNTO m	0 0 1 0	0 1 1 0	2 6 m	2	2	(T ₀) = 0 then (PC ₀ - PC ₇) + m (T ₀) = 1 then (PC) - (PC) + 2				Jumps to address m of the current page when flag T ₀ is 0, otherwise the next instruction is executed.	
JT1 m	0 1 0 1	0 1 1 0	5 6 m	2	2	(T ₁) = 1 then (PC ₀ - PC ₇) + m (T ₁) = 0 then (PC) - (PC) + 2				Jumps to address m of the current page when flag T ₁ is 1, otherwise the next instruction is executed.		
JNT1 m	0 1 0 0	0 1 1 0	4 6 m	2	2	(T ₁) = 0 then (PC ₀ - PC ₇) + m (T ₁) = 1 then (PC) - (PC) + 2				Jumps to address m of the current page when flag T ₁ is 0, otherwise the next instruction is executed.		
JFO m	1 0 1 1	0 1 1 0	B 6 m	2	2	(F ₀) = 1 then (PC ₀ - PC ₇) - m (F ₀) = 0 then (PC) - (PC) - 2				Jumps to address m of the current page when flag F ₀ is 1.		
JF1 m	0 1 1 1	0 1 1 0	7 6 m	2	2	(F ₁) = 1 then (PC ₀ - PC ₇) + m (F ₁) = 0 then (PC) - (PC) + 2				Jumps to address m of the current page when flag F ₁ is 1.		
Flag Control	CLR C	1 0 0 1	0 1 1 1	9 7	1	1	(C) = 0		○		Clears the carry flag C, resets it to 0. AC is not affected.	
	CPL C	1 0 1 0	0 1 1 1	A 7	1	1	(C) = (C̄)		○		Complements the carry flag C. AC is not affected.	
	CLR F ₀	1 0 0 0	0 1 0 1	8 5	1	1	(F ₀) = 0				Clears the flag F ₀ , resets it to 0.	
	CPL F ₀	1 0 0 1	0 1 0 1	9 5	1	1	(F ₀) = (F ₀ ̄)				Complements the flag F ₀ .	
	CLR F ₁	1 0 1 0	0 1 0 1	A 5	1	1	(F ₁) = 0				Clears flag F ₁ , resets it to 0.	
	CPL F ₁	1 0 1 1	0 1 0 1	B 5	1	1	(F ₁) = (F ₁ ̄)				Complements the flag F ₁ .	

UNIVERSAL PERIPHERAL INTERFACE

Item Type	Mnemonic	Instruction code						Hexa decimal	Bytes	Cycles	Function	Effected carry			Description		
		D ₇	D ₆	D ₅	D ₄	D ₃	D ₂					D ₁	D ₀	C		AC	None
Control	EN I	0	0	0	0	0	1	0	1	08	1	1	(INTF) ← 1				Enables outside interrupt.
	DIS I	0	0	0	1	0	1	0	1	15	1	1	(INTF) ← 0				Disables outside interrupt.
	SEL RB ₀	1	1	0	0	0	1	0	1	C5	1	1	(BS) ← 0				Selects working register bank 0.
	SEL RB ₁	1	1	0	1	0	1	0	1	D5	1	1	(BS) ← 1				Selects working register bank 1.
	EN DMA	1	1	1	0	0	1	0	1	E5	1	1					Enables DMA hand shake lines.
	EN FLAGS	1	1	1	1	0	1	0	1	F5	1	1	(PZ ₄) ← (OBF) (PZ ₂) ← (IBF)				Enables interrupts from master.
Timer/event counter control	MOV A, T	0	1	0	0	0	0	1	0	42	1	1	(A) ← (T)				Transfers the contents of timer/event counter to register A.
	MOV T, A	0	1	1	0	0	0	1	0	62	1	1	(T) ← (A)				Transfers the contents of register A to timer/event counter.
	STRT T	0	1	0	1	0	1	0	1	55	1	1					Starts timer operation of time/event counter. Minimum count cycle is 80µs.
	STRT CNT	0	1	0	0	0	1	0	1	46	1	1					Starts operation as event counter of time/event counter. Counts up when terminated. T ₁ changes to input high-level for input low-level. Minimum count cycle is 7.5µs.
	STOP TCNT	0	1	1	0	0	1	0	1	65	1	1					Stops operation of timer or event counter.
	EN TCNTI	0	0	1	0	0	1	0	1	25	1	1	(TCNTF) ← 1				Enables interrupt of timer/event counter.
	DIS TCNTI	0	0	1	1	0	1	0	1	35	1	1	(TCNTF) ← 0				Disables interrupt of timer/event counter. Resets interrupt flip-flop of CPU which is set during the CPU stands by. Timer over flow flag isn't affected.
Misc.	NOP	0	0	0	0	0	0	0	0	00	1	1					No operation. Execution time is 1 cycle.

Note 1: Executing an instruction may produce a carry (overflow or underflow). The carry may be disregarded (lost) or it may be transferred to C/AC (saved). The saving of a carry is not shown in the function equations, but is instead shown in the carry columns C and AC. The detail affection of carries for instructions ADD, ADDC and DA is as follows:

- (C) ← 1 at overflow of the accumulator is produced.
- (C) ← 0 at no overflow of the accumulator is produced.
- (AC) ← 1 at overflow of the bit 3 of the accumulator.
- (AC) ← 0 at no overflow.

2: The contents of ST₄~ST₇ is read when the host computer reads the status of M5L8041A-XXP.

UNIVERSAL PERIPHERAL INTERFACE

Symbol	Details	Symbol	Details
A	8-bit register (accumulator)	PC	Program counter
A ₀ ~A ₃	The low-order 4 bits of the register A	PC ₀ ~PC ₇	The low-order 8 bits of the program counter
A ₄ ~A ₇	The high-order 4 bits of the register A	PC ₈ ~PC ₁₀	The high-order 3 bits of the program counter
A ₀ ~A _n , A _n -1	The bits of the register A	PSW	Program status word
b	The value of the bits 5~7 of the first byte machine code	Rr	Register designator
b ₇ b ₆ b ₅	The bits 5~7 of the first byte machine code	r	Register number
BS	Register bank select	r ₀	The value of bit 0 of the machine code
BUS	Corresponds to the port 0 (bus I/O port)	r ₂ r ₁ r ₀	The value of bits 0~2 of the machine code
AC	Auxiliary carry flag	S ₂ S ₁ S ₀	The value of bits 0~2 of the stack pointer
C	Carry flag	SP	Stack pointer
DBB	Data bus buffer	ST ₆ ST ₇	Bits 4~7 of the status register
F ₀	Flag 0	STS	System status
F ₁	Flag 1	T	Timer/event counter
INTF	Interrupt flag	T ₀	Test pin 0
IBF	Input buffer full flag	T ₁	Test pin 1
m	The value of the 11-bit address	TCNTF	Timer/event counter overflow interrupt flag
m ₇ m ₆ m ₅ m ₄ m ₃ m ₂ m ₁ m ₀	The second byte (low-order 8 bits) machine code of the 11-bit address	TF	Timer flag
m ₁₀ m ₉ m ₈	The bits 5~7 of the first byte (high-order 3 bits) machine code of the 11-bit address	#	Symbol to indicate the immediate data
(M(A))	The content of the memory location addressed by the register A	@	Symbol to indicate the content of the memory location addressed by the register
(M(Rr))	The content of the memory location addressed by the register Rr	←	Shows direction of data flow
(Mx(Rr))	The content of the external memory location addressed by the register Rr	↔	Exchanges the contents of data
MBF	Memory bank flag	()	Contents of register memory location or flag
n	The value of the immediate data	Λ	Logical AND
n ₇ n ₆ n ₅ n ₄ n ₃ n ₂ n ₁ n ₀	The immediate data of the second byte machine code	V	Inclusive OR
OBF	Output buffer full flag	∨	Exclusive OR
p	Port number	—	Negation
P _p	Port designator	○	Content of flag is set or reset after execution
p ₁ p ₀	The bits of the machine code corresponding to the port number

UNIVERSAL PERIPHERAL INTERFACE

GENERAL INFORMATION

This information explains how to specify the object program for the automatic design system for mask ROMs. This system for mask ROM production has been developed to accept a customer's object program specifications for the automatic design system for a mask ROM.

The main segments of the automatic design system are:

1. The plotter instructions for mask production.
2. A check list for verifying that the customer's specifications have been met.
3. A test program to assure that the production ROMs meet specifications.

An EPROM in which a program is stored is used for a customer's specifications. A separate (set of) EPROM(s) should be produced for each object program.

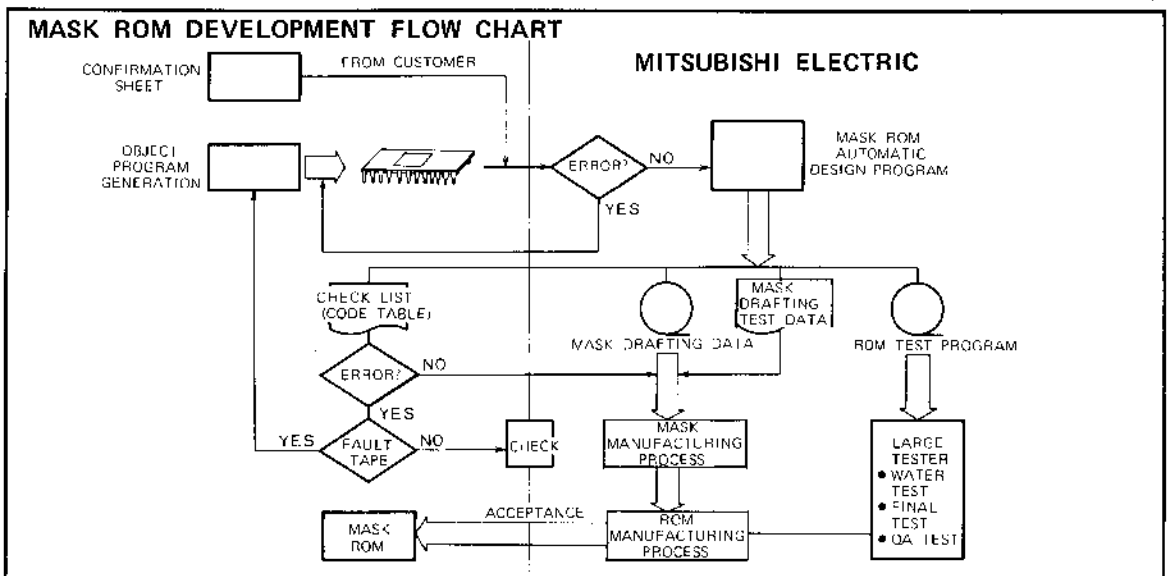

Three sets of EPROM(s) should be supplied with the confirmation material.

EPROM SPECIFICATIONS

1. The Mitsubishi M5L2708K, M5L2716K, M5L2732K or M5L8748S are standard, but Intel 2708, 2716, 2732, 8741 or 8441A or equivalent devices may be used.
2. The high-level data of both data outputs and address inputs of the supplied EPROM will be programmed as '1', and low-level as '0'.
3. All the data stored in the EPROM are considered as valid and processed to make masks.

ITEMS FOR VERIFICATION

The type of EPROM and address designation symbol A should be marked on the top of the EPROM. In addition, the address indicated by the symbol A should be indicated on the ROM verification sheet.

PROGRAMMABLE COMMUNICATION INTERFACE

DESCRIPTION

The M5L 8251AP is a universal synchronous/asynchronous receiver/transmitter (USART) IC chip designed for data communications use. It is produced using the N-channel silicon-gate ED-MOS process and is mainly used in combination with 8-bit microprocessors.

FEATURES

- Single 5V power supply
- Synchronous and asynchronous operation
 - Synchronous:
 - 5~8-bit characters
 - Internal or external synchronization
 - Automatic SYNC character insertion
 - Asynchronous system:
 - 5~8-bit characters
 - Clock rate—1, 16 or 64 times the baud rate
 - 1, 1½, or 2 stop bits
 - False-start-bit detection
 - Automatic break-state detection

- Baud rate: DC~64K-baud
- Full duplex, double-buffered transmitter/receiver
- Error detection: parity, overrun, and framing
- Pin connection and electrical characteristics compatible with Intel's 8251A

APPLICATIONS

- Modem control of data communications using micro-computers
- Control of CRT, TTY and other terminal equipment

FUNCTION

The M5L 8251AP is used in the peripheral circuits of a CPU. It permits assignments, by means of software, of operations in all the currently used serial-data transfer systems including IBM's 'bi-sync.'

PIN CONFIGURATION (TOP VIEW)

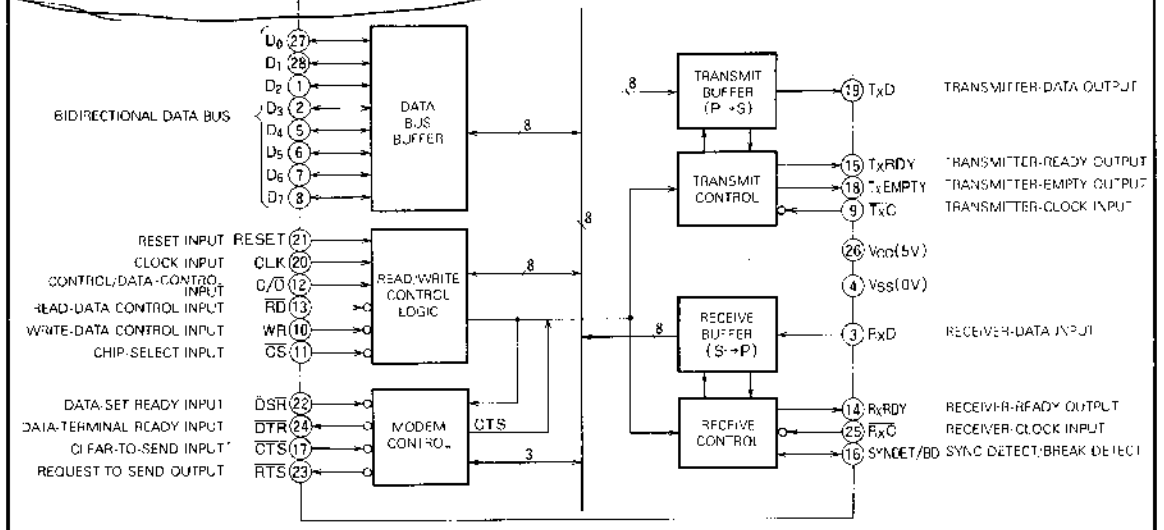

The M5L 8251AP receives parallel-format data from the CPU, converts it into a serial format, and then transmits via the Tx0 pin. It also receives data sent in via the Rx0 pin from the external circuit, and converts it into a parallel format for sending to the CPU.

On receipt of parallel-format data for transmission from the CPU or serial data for the CPU from external devices, the M5L 8251AP informs the CPU using the TxRDY or RxRDY pin. In addition, the CPU can read the M5L 8251AP status at any time.

The M5L 8251AP can detect the data received for errors and inform the CPU of the presence of errors as status information. Errors include parity, overrun and frame errors.

8

BLOCK DIAGRAM

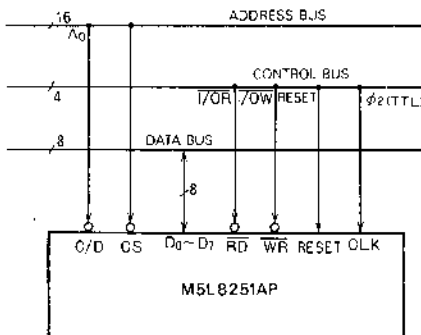

PROGRAMMABLE COMMUNICATION INTERFACE

OPERATION

The M5L 8251AP interfaces with the system bus as shown in Fig. 1, positioned between the CPU and the modem or terminal equipment, and offers all the functions required for data communication.

Fig. 1 M5L 8251AP interface to 8080A standard system bus

When using the M5L 8251AP, it is necessary to program, as the initial setting, assignments for synchronous/asynchronous mode selection, baud rate, character length, parity check, and even/odd parity selection in accordance with the communication system used. Once programming is completed, functions appropriate to the communication system can be carried out continuously.

When initial setting of the USART is completed, data communication becomes possible. Though the receiver is always in the enable state, the transmitter is placed in the transmitter-enable state (TxEN) by a command instruction, and the application of a low-level signal to the CTS pin prompts data-transfer start-up. Until this condition is satisfied, transmission is not executed. On receiving data, the receiver informs the CPU that reading of the receiver data in the USART by the CPU has become possible (the RxRDY terminal has turned to '1'). Since data reception and the entry of the CPU into the data-readable state are output as status information, the CPU can assess USART status without accessing the RxRDY terminal.

During receiving operation, the USART checks errors and gives out status information. There are three types of errors: parity, overrun, and frame. Even though an error occurs, the USART continues its operations, and the error state is retained until error reset (ER) is effected by a command instruction. The M5L 8251AP access methods are listed in Table 1.

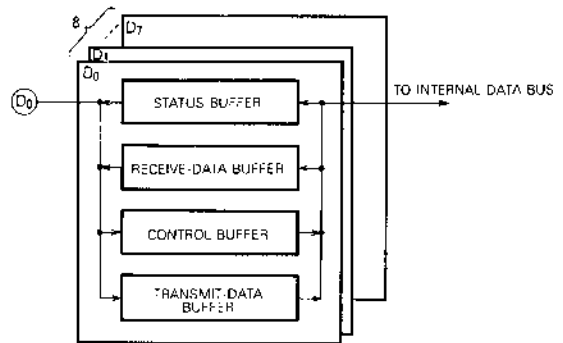

Table 1 M5L 8251AP Access Methods

C/D	RD	WR	CS	Function
L	L	H	L	Data bus ← Data in USART
L	H	L	L	USART ← Data bus
H	L	H	L	Data bus ← Status
H	H	L	L	Control ← Data bus
X	H	H	L	3-State ← Data bus
X	X	X	H	3-State ← Data bus

Data-Bus Buffer

This is an 8-bit, 3-state bidirectional bus buffer through which control words, command words, status information, and transfer data are transferred. Fig. 2 shows the structure of the data-bus buffer.

Fig. 2 Data-bus-buffer structure

Read/Write Control Logic

This logic consists of a control word register and command word register. It receives signals from the CPU control bus and generates internal-control signals for the elements.

Modem Control Circuit

This is a general-purpose control-signal circuit designed to simplify the interface to the modem. Four types of control signal are available: output signals DTR and RTS are controlled by command instructions, input signal DSR is given to the CPU as status information and input signal CTS controls direct transmission.

Transmit Buffer

This buffer converts parallel-format data given to the data-bus buffer into serial data with addition of a start bit, stop bits and a parity bit, and sends out the converted data through the TxD pin based on the control signal.

Transmit-Control Circuit

This circuit carries out all the controls required for serial-data transmission. It controls transmitter data and outputs the signals required by external devices in accordance with the instructions of the read/write control logic.

PROGRAMMABLE COMMUNICATION INTERFACE

Receive Buffer

This buffer converts serial data given via the RxD pin into a parallel format, checks the bits and characters in accordance with the communication format designated by mode setting, and transfers the assembled characters to the CPU via the data-bus buffer.

Receive Control Circuit

This circuit offers all the controls required for normal reception of the input serial data. It controls receiver data and outputs signals for the external devices in accordance with the instructions of the read/write control logic.

Clock Input (CLK)

This system-clock input is required for internal-timing generation and is usually connected to the clock-output ($\phi_{2(TTL)}$) pin of the M5L 8224P. Although there is no direct relation with the data-transfer baud rate, the clock-input (CLK) frequency is more than 30 times the \overline{TxC} or \overline{RxC} input frequency in the case of the synchronous system and more than 4.5 times in the case of the asynchronous system.

Reset Input (RESET)

Once the USART is shifted to the idle mode by a high-level input, this state continues until a new control word is set. Since this is a master reset, it is always necessary to load a control word following the reset process. The reset input requires a minimum 6-clock pulse width.

Data-Set Ready Input (DSR)

This is a general-purpose input signal, but is usually used as a data-set ready signal to test modem status. Its status can be known from the status reading process. The D_7 bit of the status information equals '1' when the \overline{DSR} pin is in the low state, and '0' when in the high state.

$$\overline{DSR} = L \rightarrow D_7 \text{ bit of status information} = 1$$

$$\overline{DSR} = H \rightarrow D_7 \text{ bit of status information} = 0$$

Note: DSR indicates modem status as follows:

- ON means the modem can transmit and receive;
- OFF means it cannot.

Data-Terminal Ready Output (\overline{DTR})

This is a general-purpose output signal, but is usually used as a data-terminal ready or rate-select signal to the modem. The \overline{DTR} pin is controlled by the D_1 bit of the command instruction; if $D_1 = 1$, $\overline{DTR} = L$, and if $D_1 = 0$, $\overline{DTR} = H$.

$$D_1 \text{ of the command register} = 1 \rightarrow \overline{DTR} = L$$

$$D_1 \text{ of the command register} = 0 \rightarrow \overline{DTR} = H$$

Chip-Select Input (CS)

This is a device-select signal that enables the USART by a low-level input. Usually, it is connected to the address bus directly or via the decoder. When this signal is in the high state, the M5L 8251AP is disabled.

Write-Data Control Input (\overline{WR})

Data and control words output from the CPU by the low-level input are written in the M5L 8251AP. This terminal is usually used in a form connected with the control bus $\overline{I/O}$ of the CPU.

Read-Data Control Input (\overline{RD})

Receiver data and status information are output from the CPU by a low-level input for the CPU data bus.

Control/Data Control Input (C/D)

This signal shows whether the information on the USART data bus is in the form of data characters or control words, or in the form of status information, in accordance with the \overline{RD} and \overline{WR} inputs while the CPU is accessing the M5L 8251AP. The high level identifies control words or status information, and the low level, data characters.

Request-To-Send Output (RTS)

This is a general-purpose output signal but is used as a request-to-send signal for the modem. The \overline{RTS} terminal is controlled by the D_5 bit of the command instruction. When D_5 is equal to '1', $\overline{RTS} = L$, and when D_5 is 0, $\overline{RTS} = H$.

$$\text{Command register } D_5 = 1 \rightarrow \overline{RTS} = L$$

$$\text{Command register } D_5 = 0 \rightarrow \overline{RTS} = H$$

Note: RTS controls the modem transmission carrier as follows:

- ON means carrier dispatch;
- OFF means carrier stop.

Clear-To-Send Input (\overline{CTS})

When the TxE bit (D_0) of the command instruction has been set to '1' and the \overline{CTS} input is low, serial data is sent out from the TxD pin. Usually this is used as a clear-to-send signal for the modem.

Note: CTS indicates the modem status as follows:

- ON means data transmission is possible;
- OFF means data transmission is impossible.

Transmission-Data Output (TxD)

Parallel-format transmission characters loaded on the M5L 8251AP by the CPU are assembled into the format designated by the mode instruction and sent in serial-data form via the TxD pin. Data is output, however, only in cases where the D_0 bit (TxE) of the command instruction is '1' and the \overline{CTS} terminal is in the low state. Once reset, this pin is kept at the mark status (high level) until the first character is sent.

Transmitter-Ready ($TxRDY$)

This signal shows that the data is ready for transmission. It is possible to confirm the status of serial-data transmission by using it as an interruption signal for the CPU or by allowing the CPU to read the D_0 bit of the status information by polling. Since the $TxRDY$ signal shows that

8

PROGRAMMABLE COMMUNICATION INTERFACE

the data buffer is empty, it is automatically reset when a transmission character is loaded by the CPU. The TxRDY bit of the status information means that the transmit-data buffer shown in Fig. 2 has become empty, while the TxRDY pin enters the high-level state only when the transmit-data buffer is empty, TxEN equals '1', and a low-level input has been applied to the CTS pin.

Status (D₀): Transmit-data buffer (TDB) is empty and '1'.

TxRDY terminal: When (TDB is empty) · (TxEN = 1) · (CTS = 0) = 1 or resetting, it becomes active.

Transmitter-Empty Output (TxEMPTY)

When no transmission characters are left in the transmit buffer, this pin enters the high state. In the asynchronous mode, the following transmission character is shifted to the transmit buffer when it is loaded from the CPU. Thus, it is automatically reset. In the synchronous mode, a SYNC character is loaded automatically on the transmit buffer when no transfer-data characters are left. In this case, however, the TxEMPTY does not enter the low state when a SYNC character has been sent out, since TxEMPTY = H denotes the state in which there is no transfer character and one or two SYNC characters are being transferred or the state in which a SYNC character is being transferred as a filler. TxEMPTY is unrelated to the TxEN bit of the command instruction.

Transmitter-Clock Input (Tx̄C)

This clock controls the baud rate for character transmission from the TxD pin. Serial data is shifted by the rising edge of the Tx̄C signal. In the synchronous mode, the Tx̄C frequency is equal to the actual baud rate. In the asynchronous mode, the frequency is specified as 1, 16, or 64 times the baud rate by the mode setting.

Example When the baud rate is 110 bauds:

- Tx̄C = 110Hz (1X)
- Tx̄C = 1.76kHz (16X)
- Tx̄C = 7.04kHz (64X)

Receiver-Data Input (Rx̄D)

Serial characters sent from another device are input to this pin and converted to a parallel-character format to serve as data for the CPU. Unless the '1' state is detected after a chip-master reset procedure (this resetting is carried out to prevent spurious operation such as that due to faulty connection of the Rx̄D to the line in a break state), the serial characters are not received. This applies to only the asynchronous mode. When the Rx̄D line enters the low state instantaneously because of noise, etc., the mis-start prevention function starts working. That is, the start bit is detected by its falling edge but in order to make sure that it

is the correct start bit, the Rx̄D line is strobed at the middle of the start bit to reconfirm the low state. If it is found to be high, a faulty-start judgment is made.

Receiver-Ready Output (RxRDY)

This signal indicates that the received characters have entered the receiver buffer, and further, the receiver-data buffer in the data-bus buffer shown in Fig. 2. It is possible to confirm the RxRDY status by using this signal as an interruption signal for the CPU or by allowing the CPU to read the D₁ bit of the status information by polling. The RxRDY is automatically reset when a character is read by the CPU. Even in the break state in which the Rx̄D line is held at low, the RxRDY remains active. It can be masked by making the Rx̄E (D₂) of the command instruction '0'.

Receiver-Clock Input (Rx̄C)

This clock signal controls the baud rate for the sending in of characters via the Rx̄D pin. The data is shifted in by the rising edge of the Rx̄C signal. In the synchronous mode, the Rx̄C frequency is equal to the actual baud rate. In the asynchronous mode, the frequency is specified as 1, 16, or 64 times the baud rate by mode setting. This relationship is parallel to that of Tx̄C, and in usual communication-line systems the transmission and reception baud rates are equal. The Tx̄C and Rx̄C terminals are, therefore, used connected to the same baud-rate generator.

Sync Detect/Break Detect Output-Input (SYNDET/BD)

In the synchronous mode this pin is used for input and output operations. When it is specified for the internal synchronous mode by mode setting, this pin works as an output terminal. It enters the high state when a SYNC character is received through the Rx̄D pin. If the M5L 8251AP has been programmed for double SYNC characters (bi-sync), a high is entered in the middle of the last bit of the second SYNC character. This signal is automatically reset by reading the status information.

On designation of the M5L8251AP to the external synchronous mode, this pin begins to serve for input operations. Applying a high signal to this pin prompts the M5L 8251AP to begin assembling data characters at the next rising edge of the Rx̄C. For the width of a high-level signal to be input, a minimum Rx̄C period is required.

Designation of the asynchronous mode causes this pin to function as a BD (output) pin. When the start, data, and parity bits and a stop bit are all in the low state, a high is entered. The BD (break detect) signal can also be read as the D₆ bit of the status information. This signal is reset by resetting the chip master or by the Rx̄D line's recovering the high state.

PROGRAMMABLE COMMUNICATION INTERFACE

PROGRAMMING

It is necessary for the M5L 8251AP to have the control word loaded by the CPU prior to data transfer. This must always be done following any resetting operation (by external RESET pin or command instruction IR). There are two types of control words: mode instructions specifying general operations required for communications and command instructions to control the M5L 8251AP's actual operations.

Following the resetting operation, a mode instruction must be set first. This instruction sets the synchronous or asynchronous system to be used. In the synchronous system, a SYNC character is loaded from the CPU. In the case of the bi-sync system, however, a second SYNC character must be loaded in succession.

Loading a command instruction makes data transfer possible. This operation after resetting must be carried out for initializing the M5L 8251AP. The USART command instruction contains an internal-reset IR instruction (D₆ bit) that makes it possible to return the M5L 8251AP to its reset state. The initialization flowchart is shown in Fig. 3, and the mode-instruction and command-instruction formats are shown in Figs. 4 and 5.

Fig. 3 Initialization flow chart

Fig. 4 Mode-instruction format

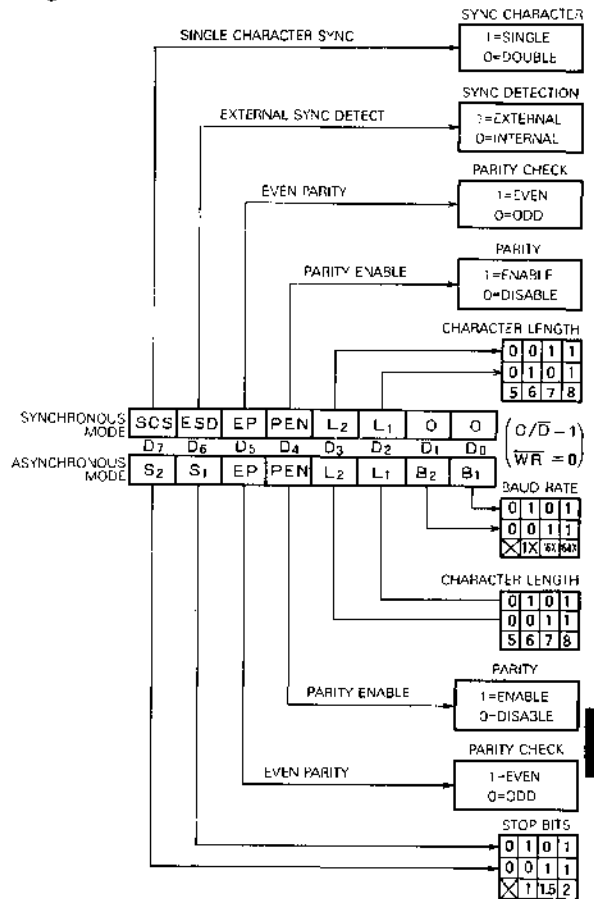

Fig. 5 Command-instruction format

PROGRAMMABLE COMMUNICATION INTERFACE

Asynchronous Transmission Mode

When data characters are loaded on the M5L 8251AP after initial setting, the USART automatically adds a start bit (low), an odd or even parity bit specified by the mode instruction during initialization, and a specified number of stop bits (high). After that, the assembled data characters are transferred as serial data via the TxD pin if transfer is enabled ($T_xEN = 1 \cdot \overline{CTS} = L$). In this case, the transfer data (baud rate) is shifted by the mode instruction at a rate of 1X, 1/16X, or 1/64X the $\overline{T_xC}$ period.

If the data characters are not loaded on the M5L 8251AP, the TxD pin enters a mark state (high). When SBRK is programmed by the command instruction, break characters (low) are output continuously through the TxD pin.

Asynchronous Reception Mode

The RxD line usually starts operations in a mark state (high), triggered by the falling edge of a low-level pulse when it comes to this line. This signal is again strobed at the middle of the bit to confirm that it is a perfect start bit. The detection of a second low indicates the validity of the start bit (restrobing is carried out only in the case of 16X and 64X). After that, the bit counter inside the M5L 8251AP starts operating; each bit of the serial information on the RxD line is shifted in by the rising edge of $\overline{R_xC}$, and the data bit, parity bit (when necessary), and stop bit are sampled at the middle position.

The occurrence of a parity error causes the setting of a parity-error flag. If the stop bit is in the low state, a frame-error flag is set. Attention should be paid to the fact that the receiver requires only one stop bit even though the program has designated 1½ or 2 stop bits.

Reception up to the stop bit means reception of a complete character. This character is then transferred to the receiver-data buffer shown in Fig. 2, and the RxD RDY

becomes active. In cases where this character is not led by the CPU and where the next character is transferred to the receiver-data buffer, the preceding character is destroyed and an overrun-error flag is set.

These error flags can be read as the M5L 8251AP status information. The occurrence of an error does not stop USART operations. The error flags are cleared by the ER (D_4 bit) of the command instruction.

The asynchronous-system transfer formats are shown in Figs. 6 and 7.

Synchronous Transmission Mode

In this mode the TxD pin remains in the high state until initial setting by the CPU is completed. After initialization, the state of $\overline{CTS} = L$ and $T_xEN = 1$ causes serial transmission of SYNC characters through the TxD pin. Then, data characters are sent out and shifted by the falling edge of the $\overline{T_xC}$ signal. The transmission rate equals the $\overline{T_xC}$ rate.

Thus, once data-character transfer starts, it must continue through the TxD pin at the same rate as that of $\overline{T_xC}$. Unless data characters are provided from the CPU before the transmitter buffer becomes empty, one or two SYNC characters are automatically output from the TxD pin. In this case, it should be noted that the T_xEMPTY pin enters the high state when there are no data characters left in the M5L8251AP to be transferred, and that the low state is not entered until the USART is provided with the next data character from the CPU. Care should also be taken over the fact that merely setting a command instruction does not effect SYNC-character insertion, because the SYNC character is sent out after loading of the data characters.

In this mode, too, break characters are sent out in succession from the TxD pin when SBRK is designated ($D_3 = 1$) by a command instruction.

Fig. 6 Asynchronous transmission format I (transmission)

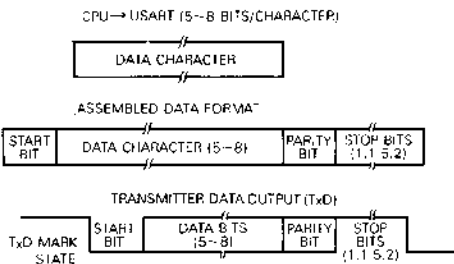

Fig. 7 Asynchronous transmission format II (reception)

Note: When the data character is 5, 6, or 7 bits/character length, the unused bits (for USART → CPU) are set to zero.

PROGRAMMABLE COMMUNICATION INTERFACE

Synchronous Reception Mode

Character synchronization in this mode is carried out internally or externally by initial-setting designation.

Programming in the internal synchronous mode requires that an EH instruction ($D_7 = 1$, enter hunt mode) is included in the first command instruction. Data on the RxD pin is sampled by the rising $\overline{R_xC}$ signal, and the receiver-buffer contents are compared with the SYNC character each time a bit is input. Comparison continues until an agreement is reached. When the M5L 8251AP has been programmed in the bi-sync mode, data received in further succession is compared. The detection of two SYNC characters in succession makes the USART end the hunt mode, setting the SYNDET pin to the high state. This reset operation is prompted by the reading of the status information. When the parity has been programmed, SYNDET is not set in the middle of the last data bit but in the middle of the parity bit.

In the external synchronous mode, the M5L 8251AP gets out of the hunt mode when a high synchronization signal is given to the SYNDET pin. The high signal requires a minimum duration of one $\overline{R_xC}$ cycle. In the asynchronous mode, however, the EH signal does not affect the operation at all.

Parity and overrun errors are checked in the same way as in the asynchronous system. During hunt-mode operations the parity bit is not checked, but parity checking is carried out even when the receiver is disabled.

The CPU can command the receiver to enter the hunt mode, if synchronization is lost. This prevents the SYNC character from erroneously becoming equal to the received data when all the data in the receiver buffer is set to '1'. Attention should be paid to the fact that the SYNDET F/F

is reset each time status information is read irrespective of the synchronous mode's being internal or external. This, however, does not return the M5L 8251AP to the hunt mode. Synchronism detection is carried out even though it is not the hunt mode. The synchronous transfer formats are shown in Figs. 8 and 9.

Command Instruction

This instruction defines actual operations in the communication mode designated by mode setting. Command instructions include transmitter/receiver enable error-reset, internal-reset, modem-control, enter-hunt and break transmission instructions.

The mode is set following the reset operation. A SYNC character is set as required, and the writing of high-level signals on the control/data pin (C/D) that follows it is regarded as a command instruction. When the mode is set all over again from the beginning, the M5L 8251AP can be reset by using inputting via the reset terminal or by internal resetting based on the command instruction.

Note 1: The command error reset (ER), internal reset (IR) and enter-hunt-mode (EH) operations are only effective when the command instruction is loaded, so that these bits need not be returned to '0'.

2: When a break character is sent out by a command, the TxD enters the low state immediately irrespective of whether or not the USART has sent out data.

3: Operations of the USART's receiver section which is always in the enable state cannot be inhibited. The command instruction $R_xE = 0$ does not mean that data reception via the RxD pin is inhibited; it means that the R_xRDY is masked and error flags are inhibited.

8

Fig. 8 Synchronous transmission format I (transmission)

Fig. 9 Synchronous transmission format II (reception)

Note: When the data character is 5, 6, or 7 bits/character length, the unused bits (for USART → CPU) are set to zero.

PROGRAMMABLE COMMUNICATION INTERFACE

Status Information

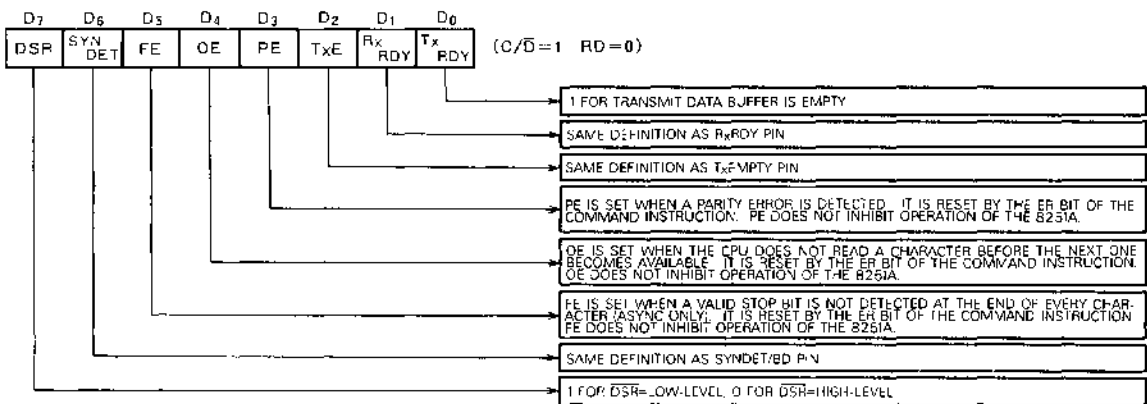

The CPU can always read USART status by setting the C/\bar{D} to '1' and \bar{RD} to '0'.

The status information format is shown in Fig. 10. In this format R_xRDY , T_xEMPTY and $SYNDET$ have the same definitions as those of the pins. This means that these three pieces of status information become '1' when each pin is in the high state. The other status information is defined as follows:

DSR: When the \bar{DSR} pin is in the low state, status information DSR becomes '1'.

- FE: The occurrence of a frame error in the receiver section makes the status information FE '1'.
- OE: The occurrence of an overrun error in the receiver section makes the status information OE '1'.
- PE: The occurrence of a parity error in the receiver section makes this status information PE '1'.
- T_xRDY : This information becomes '1' when the transmit-data buffer is empty. Be careful because this has a different meaning from the T_xRDY pin that enters the high state only when the transmitter buffer is empty, when the \bar{CTS} pin is in the low state, and when T_xEN is '1'.

Fig. 10 Status information

APPLICATION EXAMPLES

Fig. 11 shows an application example for the M5L 8251AP in the asynchronous mode. When the port addresses of the M5L 8251AP are assumed to be 00# and 01# in this figure, initial setting in the asynchronous mode is carried out in the following manner:

```

MVI    A, B6#    Mode setting
OUT    01#
MVI    A, 27#    Command instruction
OUT    01#
    
```

In this case, the following are set by mode setting:

- Asynchronous mode
- 6 bits/character
- Parity enable (even)
- 1½ stop bits
- Baud rate: 16X

Command instructions set the following:

```

RTS = 1 →  $\bar{RTS}$  pin = L
RxE = 1
DTR = 1 →  $\bar{DTR}$  pin = L
TxEN = 1
    
```

When the initial setting is complete, transfer operations are allowed. The \bar{RTS} pin is initially set to the low-level by setting RTS to '1', and this serves as a \bar{CTS} input with

T_xEN being equal to '1'. For this reason the same definition applies to the status and pin of T_xRDY , and '1' is assigned when the transmit-data buffer is empty. Actual transfer of data is carried out in the following way:

```
IN    01#    Status read
```

The IN instruction prompts the CPU to read the USART's status. The result is: if the T_xRDY equals '1' transmitter data is sent from the CPU and written on the M5L 8251AP. Transmitter data is written in the M5L 8251AP in the following manner:

```

MVI    A, 2D#    2D16 is an example of
                  transmitter data.
OUT    00#    USART ← (A)
    
```

Receiver data is read in the following manner:

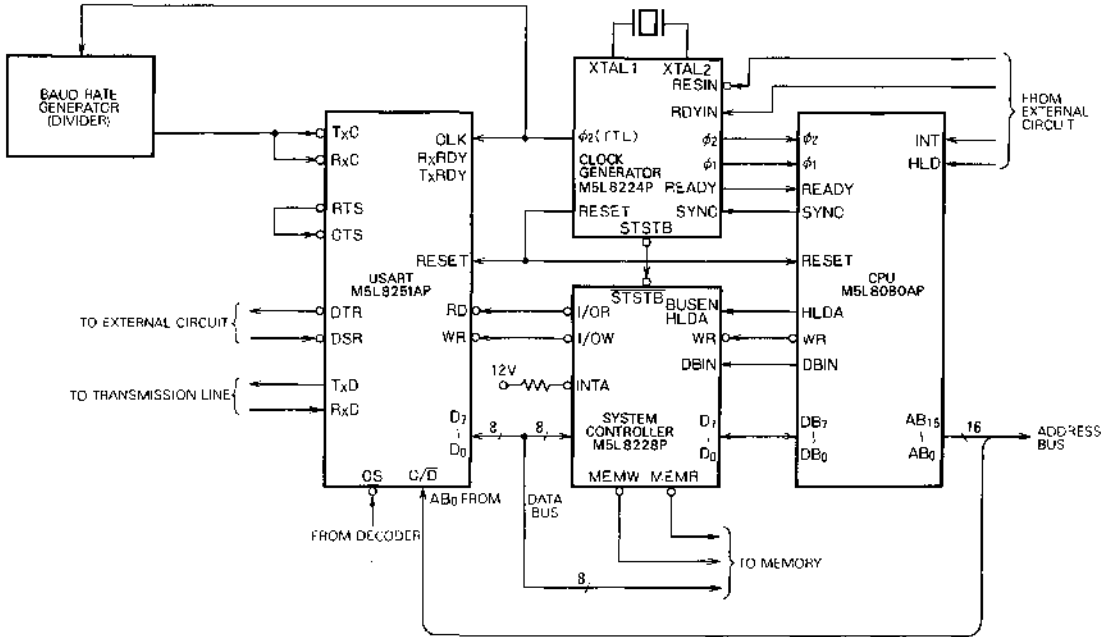

```
IN    00#    (A) ← USART
```

In the above example, the status information is read and as a result, the transmitter data is written and read. Interruption processing by using the T_xRDY and R_xRDY pins is also possible.

Fig. 12 shows the status of the T_xD pin when data written in the USART is transferred from the CPU. When the data shown in Fig. 12 enters the R_xD pin, data sent from the M5L 8251AP to the CPU becomes 2D₁₆ and bits D₆ and D₇ are treated as '0'.

PROGRAMMABLE INTERVAL TIMER

DESCRIPTION

The M5L8253P-5 is a programmable general-purpose timer device developed by using the N-channel silicon-gate ED-MOS process. It offers counter and timer functions in systems using an 8-bit parallel-processing CPU. The use of the M5L8253P frees the CPU from the execution of looped programs, count-operation programs and other simple processing involving many repetitive operations, thus contributing to improved system throughputs. The M5L8253P-5 works on a single power supply, and both its input and output can be connected to a TTL circuit.

FEATURES

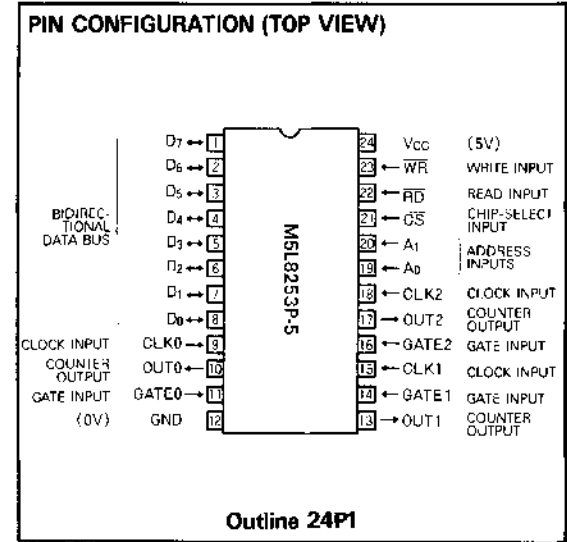

- M5L8253P-5 is suitable for use with MELPS 85
- 3 independent built-in 16-bit down counters
- Clock period: DC~2MHz
- 6 counter modes freely assignable for each counter
- Binary or decimal counts
- Single 5V power supply
- Pin connection and electric characteristics compatible with Intel's 8253

APPLICATIONS

Delayed-time setting, pulse counting and rate generation in microcomputers.

FUNCTION

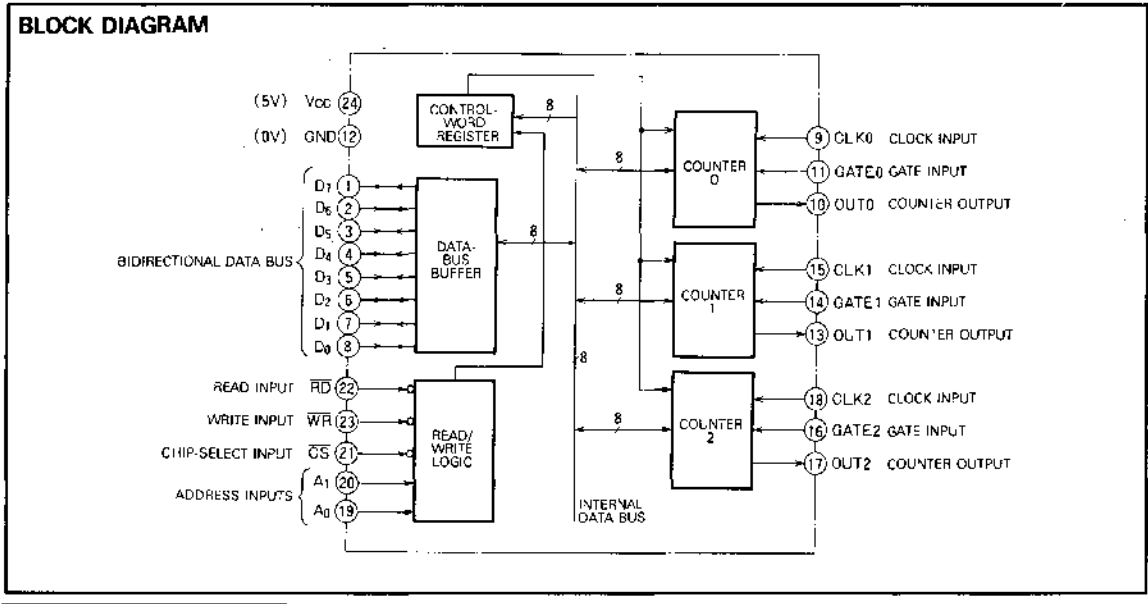

Three independent 16-bit counters allow free programming based on mode-control instructions from the CPU. When roughly classified, there are 6 modes (0~5). Mode 0 is mainly used as an interruption timer and event counter, mode 1 as a digital one-shot, modes 2 and 3 as rate gener-

8

rators, mode 4 for a software triggered strobe, and mode 5 for a hardware triggered strobe.

The count can be monitored and set at any time. The counter operates with either the binary or BCD system.

PROGRAMMABLE INTERVAL TIMER

DESCRIPTION OF FUNCTIONS

Data-Bus Buffer

This 3-state, bidirectional, 8-bit buffer is used to interface the M5L8253P-5 to the system-side data bus. Transmission and reception of all the data including control words for mode designation and values written in, and read from, the counters are carried out through this buffer.

Read/Write Logic

The read/write logic accepts control signals (\overline{RD} , \overline{WR}) from the system and generates control signals for each counter. It is enabled or disabled by the chip-select signal (\overline{CS}); if CS is at the high-level the data-bus buffer enters a floating (high-impedance) state.

Read Input (\overline{RD})

The count of the counter designated by address inputs A_0 and A_1 on the low-level is output to the data bus.

Write Input (\overline{WR})

Data on the data bus is written in the counter or control-word register designated by address inputs A_0 and A_1 on the low-level.

Address Inputs (A_0, A_1)

These are used for selecting one of the 3 internal counters and either of the control-word registers.

Chip-Select Input (\overline{CS})

A low-level on this input enables the M5L8253P-5. Changes in the level of the CS input have no effect on the operation of the counters.

Control-Word Register

This register stores information required to give instructions about operational modes and to select binary or BCD counting. Unlike the counters, it allows no reading, only writing.

Counters 0, 1 and 2

These counters are identical in operation and independent of each other. Each is a 16-bit, presettable, down counter, and has clock-input, gate-input and output pins. The counter can operate in either binary or BCD using the falling edge of each clock. The mode of counter operation and the initial value from which to start counting can be designated by software. The count can be read by input instruction at any time, and there is a "read-on-the-fly" function which enables stable reading by latching each instantaneous count to the registers by a special counter-latch instruction.

Table 1 Basic Functions

\overline{CS}	\overline{RD}	\overline{WR}	A_1	A_0	Function
0	1	0	0	0	Data bus \rightarrow Counter 0
0	1	0	0	1	Data bus \rightarrow Counter 1
0	1	0	1	0	Data bus \rightarrow Counter 2
0	1	0	1	1	Data bus \rightarrow Control-word register
0	0	1	0	0	Data bus \leftarrow Counter 0
0	0	1	0	1	Data bus \leftarrow Counter 1
0	0	1	1	0	Data bus \leftarrow Counter 2
0	0	1	1	1	3-state
1	\times	\times	\times	\times	3-state
0	1	1	\times	\times	3-state

PROGRAMMABLE INTERVAL TIMER

CONTROL WORD AND INITIAL-VALUE LOADING

The function of the M5L8253P-5 depends on the system software. The operational mode of the counters can be specified by writing control words ($A_0, A_1 = 1, 1$) into the control-word registers.

The programmer must write out to the M5L8253P-5 the programmed number of count register bytes (1 or 2) prior to actually using the selected counter.

Table 2 shows control-word format, which consists of 4 fields. Only the counter selected by the D_7 and D_6 bits of the control word is set for operation. Bits D_5 and D_4 are used for specifying operations to read values in the counter and to initialize. Bits $D_3 \sim D_1$ are used for mode designation, and D_0 for specifying binary or BCD counting. When $D_0 = 0$, binary counting is employed, and any number from 0000_{16} to $FFFF_{16}$ can be loaded into the count register. The counter is counted down for each clock. The counting of 0000_{16} causes the transmission of a time-out signal from the count-output pin.

The maximum number of counts is obtained when 0000_{16} is set as the initial value. When $D_0 = 1$, BCD counting is employed, and any number from 0000_{10} to 9999_{10} can be loaded on the counter.

Neither system resetting nor connecting to the power supply sets the control word to any specific value. Thus to bring the counters into operation, the above-mentioned control words for mode designation must be given to each counter, and then 1~2 byte initial counter values must be set. The following is an example of this programming step.

To designate mode 0 for counter 1, with initial value 8253_{16} set by binary count, the following program is used:

```

MVI A, 7016   Control word 7016
OUT n1       n1 is control-word-register address
MVI A, 5316   Low-order 8 bits
OUT n2       n2 is counter 1 address
MVI A, 8216   High-order 8 bits
OUT n2       n2 is counter 1 address
    
```

Thus, the program generally has the following sequence:

- (1) Control-word output to counter i ($i = 0, 1, 2$).
- (2) Initialization of low-order 8 counter bits
- (3) Initialization of high-order 8 counter bits

The three counters can be executed in any sequence. It is possible, for instance, to designate the mode of each counter and then load initial values in a different order. Initialization of the counters designated by RL1 and RL0 must be executed in the order of the low-order 8 bits and then the high-order 8 bits for the counter in question.

Table 2 Control-Word Format

PROGRAMMABLE INTERVAL TIMER

MODE DEFINITION

Mode 0 (Interrupt on Terminal Count)

Mode set and initialization cause the counter output to go low-level (see Fig. 1). When the counter is loaded with an initial value, it will start counting the clock input. When the terminal count is reached, the output will go high and remain high until the selected count register is reloaded with the mode. This mode can be used when the CPU is to be interrupted after a certain period or at the time of counting up.

Fig. 1 shows a setting of 4 as the initial value. If gate input goes low, counting is inhibited for the duration of the low-level period.

Reloading of the initial value during count operation will stop counting by the loading of the first byte and start the new count by the loading of the second byte.

Mode 1 (Programmable One-Shot)

The gate input functions as a trigger input. A gate-input rising edge causes the generation of low-level one-shot output with a predetermined clock length starting from the next clock. Fig. 2 shows an initial setting of 4. While the counter output is at the low-level (during one-shot), loading of a new value does not change the one-shot pulse width, which has already been output. The current count can be read at any time without affecting the width of the one-shot pulse being output. This mode permits retriggering.

Mode 2 (Rate Generator)

Low-level pulses during one clock operation are generated from the counter output at a rate of one per n clock inputs (where n is the value initially set for the counter). When a new value is loaded during the counter operation, it is reflected on the output after the pulses by the current count have been output. In the example shown in Fig. 3, n is given as 4 at the outset and is then changed to 3.

In this mode, the gate input provides a reset function. While it is on the low-level, the output is maintained high; the counter restarts from the initial value, triggered by a rising gate-input edge. This gate input, therefore, makes possible external synchronization of the counter by hardware.

After the mode is set, the counter does not start counting until the rate n is loaded into the count register, with the counter output remaining at the high-level.

Mode 3 (Square Rate Generator)

This is similar to Mode 2 except that it outputs a square wave with the half count of the set rate. When the set value n is odd, the square-wave output will be high for $(n + 1)/2$ clock-input counts and low for $(n - 1)/2$ counts. When a

new rate is reloaded into the count register during its operation, it is immediately reflected on the count directly following the output transition (high-to-low or low-to-high) of the current count. Gate-input operations are exactly the same as in Mode 2. Fig. 4 shows an example of Mode 3 operation.

Mode 4 (Software Triggered Strobe)

After the mode is set, the output will be high. By loading a number on the counter, however, clock-input counts can be started and on the terminal count, the output will go low for one input-clock period and then will go high again. Mode 4 differs from Mode 2 in that pulses are not output repeatedly with the same set count. The pulse output is delayed one clock period in Mode 2, as shown in Fig. 5. When a new value is loaded into the count register during its count operation, it is reflected on the next pulse output without affecting the current count. The count will be inhibited while the gate input is low-level.

Mode 5 (Hardware Triggered Strobe)

This is a variation of Mode 1. The gate input provides a trigger function, and the count is started by its rising edge. On the terminal count, the counter output goes low for one clock period and then goes high. As in Mode 1, retriggering by the gate input is possible. An example of timing in Mode 5 is shown in Fig. 6.

As mentioned above, the gate input plays different roles according to the mode. The functions are summarized in Table 3.

Table 3 Gate Operations

Gate Mode	Low or going low	Rising	High
0	Disables counting		Enables counting
1		(1) Initiates counting (2) Resets output after next clock	
2	(1) Disables counting (2) Sets output high immediately	Initiates counting	Enables counting
3	(1) Disables counting (2) Sets output high immediately	Initiates counting	Enables counting
4	Disables counting		Enables counting
5		Initiates counting

COUNTER MONITORING

Sometimes the counter must be monitored by reading its count or using it as an event counter. The M5L8253P-5 offers the following two methods for count reading:

Read Operation

The count can be read by designating the address of the counter to be monitored and executing a simple I/O read operation. In order to ensure correct reading of the count, it is necessary to cause the clock input to pause by external logic or prevent a change in the count by gate input. An example of a program to read the counter 1 count is shown below. If RL1, RLO = 1, 1 has been specified in the control word, the first IN instruction enables the low-order 8 bits to be read and the second IN instruction enables the high-order 8 bits.

```
IN    n2 . . . . n2 is the counter 1 address
MOV  D, A
IN    n2
MOV  E, A
```

The IN instruction should be executed once or twice by the RL1 and RLO designations in the control-word register.

Read-on-the-Fly Operation

This method makes it possible to read the current count without affecting the count operation at all. A special counter-latch command is first written in the control-word register. This causes latching of all the instantaneous counts to the register, allowing retention of stable counts. An example of a program to execute this operation for counter 2 is given below.

```
MVI  A, 1000XXXX . . . D5 = D4 = 0 designates counter latching
OUT  n1 . . . . n1 is the control-word-register address
IN   n3 . . . . n3 is the counter 2 address
MOV  D, A
IN   n3
MOV  E, A
```

In this example, the IN instruction is executed twice. Due to the internal logic of the M5L8253P-5 it is absolutely essential to complete the entire reading procedure. If two bytes are programmed to be read, then two bytes must be read before any OUT instruction can be executed to the same counter.

PROGRAMMABLE PERIPHERAL INTERFACE

DESCRIPTION

This is a family of general-purpose programmable input/output devices designed for use with the M5L 8085A 8-bit parallel CPU as input/output ports. These devices are fabricated using N-channel silicon-gate ED-MOS technology for a single supply voltage. They are simple input and output interfaces for TTL circuits, having 24 input/output pins which correspond to three 8-bit input/output ports.

FEATURES

- 24 programmable I/O pins
- Single 5V supply voltage
- TTL-compatible $I_{OL} = 2.5\text{mA}$ (max)
- Fully compatible with MELPS 8 microprocessor series
- Direct bit set/reset capability
- Interchangeable with Intel's 8255A in terms of function, electrical characteristics and pin configuration

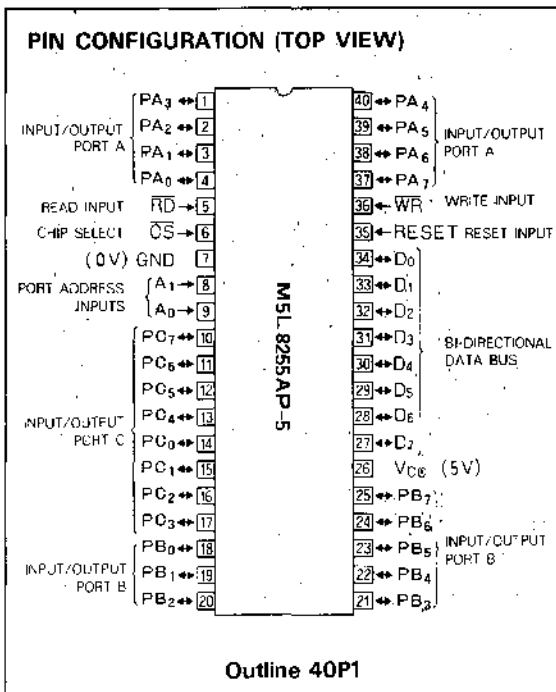

APPLICATION

- Input/output ports for MELPS 8/85 microprocessor

FUNCTION

These PPIs have 24 input/output pins which may be individually programmed in two 12-bit groups A and B with mode control commands from a CPU. They are used in three major modes of operation, mode 0, mode 1 and mode 2.

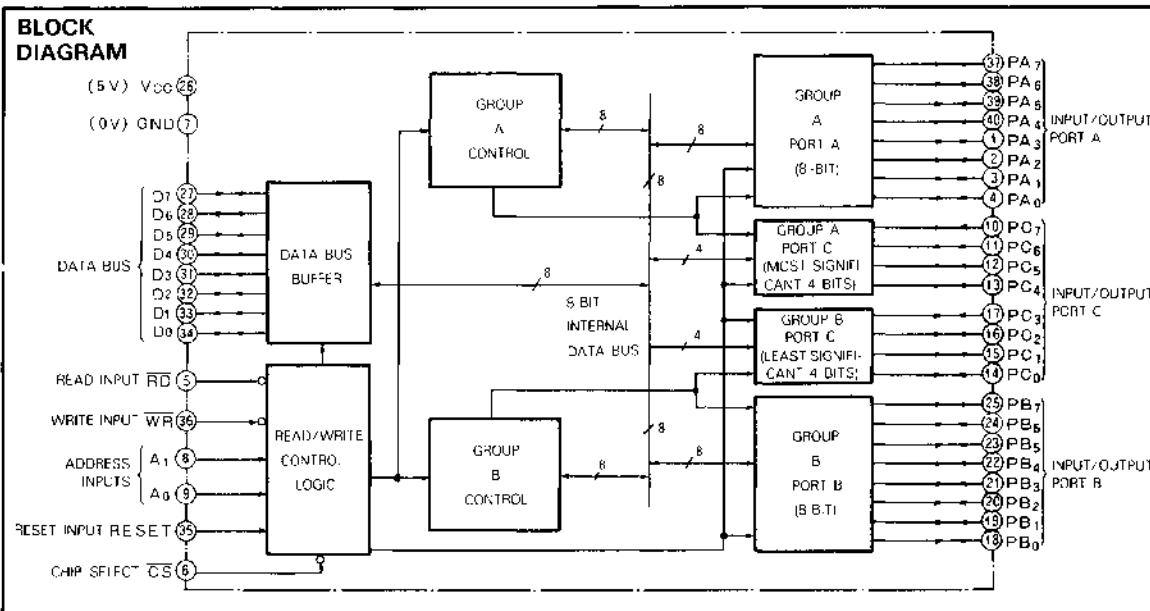

Operating in mode 0, each group of 12 pins may be programmed in sets of 4 to be inputs or outputs. In mode 1, the 24 I/O terminals may be programmed in two 12-bit groups, group A and group B. Each group contains one 8-bit data port, which may be programmed to serve as input

or output, and one 4-bit control port used for handshaking and interrupt control signals. Mode 2 is used with group A only, as one 8-bit bidirectional bus port and one 5-bit control port.

Bit set/reset is controlled by CPU. A high-level reset input (RESET) clears all internal registers, and all ports are set to the input mode (high-impedance state).

8

PROGRAMMABLE PERIPHERAL INTERFACE

FUNCTIONAL DESCRIPTION

Data Bus Buffer

This three-state, bidirectional, eight-bit buffer is used to transfer the data when an input or output instruction is executed by the CPU. Control words and status information are also transferred through the data bus buffer.

Read/Write Control Logic

The function of this block is to control transfers of both data and control words. It accepts the address signals (A_0 , A_1 , \overline{CS}) from the CPU, I/O control bus outputs (\overline{RD} , \overline{WR}) from the system controller, and RESET signals, and then issues commands to both of the control groups in the PPI.

\overline{CS} (Chip-Select) Input

At low-level, the communication between the PPI and the CPU is enabled. While at high-level, the data bus is kept in the high-impedance state, so that commands from the CPU are ignored. Then the previous data is kept at the output port.

\overline{RD} (Read) Input

At low-level, the status or data at the port is transferred to the CPU from the PPI. In essence, it allows the CPU to read data from the PPI.

\overline{WR} (Write) Input

At low-level, the data or control words are transferred from the CPU and written in the PPI.

A_0 , A_1 (Port Address) Input

These input signals are used to select one of the three ports: port A, port B, and port C, or the control register. They are normally connected to the least significant two bits of the address bus.

RESET (Reset) Input

At high-level, all internal registers, including the control register, are cleared. Then all ports are set to the input mode (high-impedance state).

Group A and Group B Control

Accepting commands from the read/write control logic, the control blocks (Group A, Group B) receive 8-bit control words from the internal data bus and issue the proper commands for the associated ports. Control group A is associated with port A and the four high-order bits of port C. Control group B is associated with port B and the four low-order bits of port C. The control register, which stores control words, can only be written into.

Port A, Port B and Port C

The PPI contains three 8-bit ports whose modes and input/output settings are programmed by the system software.

Port A has an output latch/buffer and an input latch. Port B has an I/O latch/buffer and an input buffer. Port C has an output latch/buffer and an input buffer. Port C can

be divided into two 4-bit ports which can be used as ports for control signals for port A and port B.

The basic operations are shown in Table 1.

Table 1 Basic Operations

A_1	A_0	\overline{CS}	\overline{RD}	\overline{WR}	Operation
0	0	0	0	1	Data bus \leftarrow Port A
0	1	0	0	1	Data bus \leftarrow Port B
1	0	0	0	1	Data bus \leftarrow Port C
0	0	0	1	0	Port A \leftrightarrow Data bus
0	1	0	1	0	Port B \leftrightarrow Data bus
1	0	0	1	0	Port C \leftrightarrow Data bus
1	1	0	1	0	Control register \leftarrow Data bus
X	X	1	X	X	Data bus is in high-impedance state.
1	1	0	0	1	Illegal condition

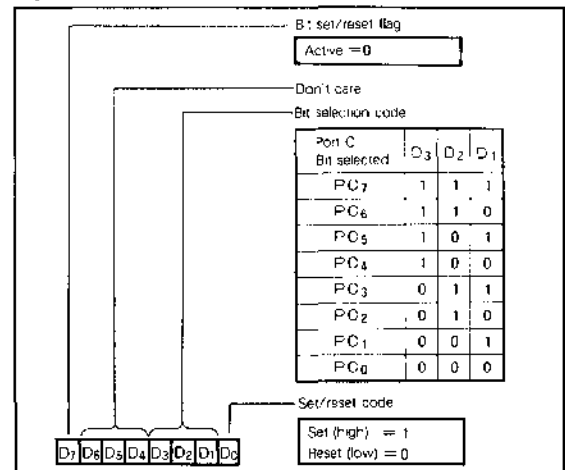

Where, "0" indicates low level

"1" indicates high level

Bit Set/Reset

When port C is used as an output port, any one bit of the eight bits can be set (high) or reset (low) by a control word from the CPU. This bit set/reset can be operated in the same way as the mode set, but the control word format is different. This operation is also used for INTE set/reset in mode 1 and mode 2.

Fig. 1 Control word format for port C set/reset

PROGRAMMABLE PERIPHERAL INTERFACE

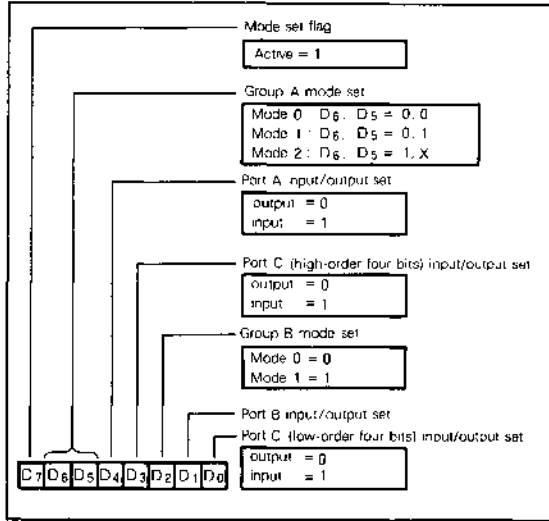

BASIC OPERATING MODES

The PPI can operate in any one of three selected basic modes.

- Mode 0: Basic input/output (group A, group B)
- Mode 1: Strobed input/output (group A, group B)
- Mode 2: Bidirectional bus (group A only)

The mode of both group A and group B can be selected independently. The control word format for mode set is shown in Fig. 2.

Fig. 2 Control word format for mode set.

1. Mode 0 (Basic Input/Output)

This functional configuration provides simple input and output operations for each of the three ports. No "hand-shaking" is required; data is simply written in, or read from, the specified port. Output data from the CPU to the port can be held, but input data from the port to the CPU cannot be held. Any one of the 8-bit ports and 4-bit ports can be used as an input port or an output port. The diagrams following show the basic input/output operating modes.

PROGRAMMABLE PERIPHERAL INTERFACE

2. Mode 1 (Strobed Input/Output)

This function can be set in both group A and B. Both groups are composed of one 8-bit data port and one 4-bit control data port. The 8-bit port can be used as an input port or an output port. The 4-bit port is used for control and status signals affecting the 8-bit data port. The following shows operations in mode 1 for using input ports.

STB (Strobed Input)

A low-level on this input latches the output data from the terminal units into the input register of the port. In short, this is a lock for data latching. The data from the terminal units can be latched by the PPI independent of the control signal from the CPU. This data is not sent to the data bus until the instruction IN is executed.

IBF (Input Buffer Full Flag Output)

A high-level on this output indicates that the data from the terminal units has been latched into the input register. IBF is set to high-level by the falling edge of the \overline{STB} input, and is reset to low-level by the rising edge of the \overline{RD} input.

INTR (Interrupt Request Output)

This can be used to interrupt the CPU when an input device is requesting service. When INTE (interrupt enable flag) of the PPI is high-level, INTR is set to high-level by the rising edge of the \overline{STB} input and is reset to low-level by the falling edge of \overline{RD} input.

INTE_A of group A is controlled by bit setting of PC₄. INTE_B of group B is controlled by bit setting of PC₂.

Mode 1 input state is shown in Fig. 3, and the timing chart is shown in Fig. 4.

Fig. 3 An example of mode 1 input state

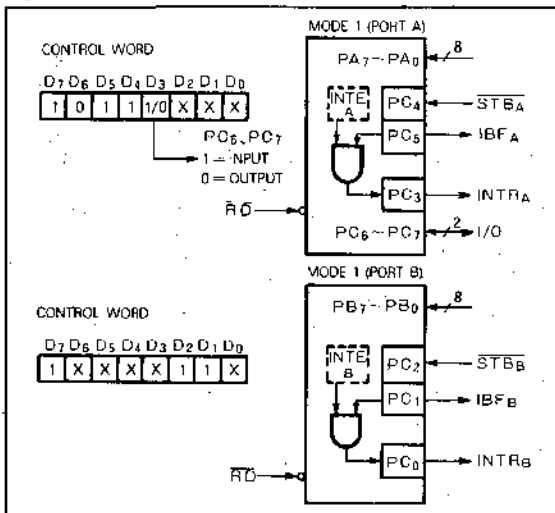

Fig. 4 Timing chart

The following shows operations using mode 1 for output ports.

\overline{OBF} (Output Buffer Full Flag Output)

This is reset to low-level by the rising edge of the \overline{WR} signal and is set to high-level by the falling edge of the \overline{ACK} (acknowledge input). In essence, the PPI indicates to the terminal units by the \overline{OBF} signal that the CPU has sent data to the port.

ACK (Acknowledge Input)

Receiving this signal from a terminal unit can indicate to the PPI that the terminal unit has accepted data from a port.

INTR (Interrupt Request)

When a peripheral unit is accepting data from the CPU, setting INTR to high-level can be used to interrupt the CPU. When INTE (interrupt enable flag) is high and \overline{OBF} is set to high-level by the rising edge of an \overline{ACK} signal, then INTR will also be set to high-level by the rising edge of the \overline{ACK} signal. Also, INTR is reset to low-level by the falling edge of the \overline{WR} signal when the PPI has been receiving data from the CPU.

INTE_A of group A is controlled by bit setting of PC₄.

INTE_B of group B is controlled by bit setting of PC₂.

Mode 1 output state is shown in Fig. 5, and the timing chart is shown in Fig. 6.

Combinations for using port A and port B as input or output in mode 1 are shown in Fig. 7 and Fig. 8.

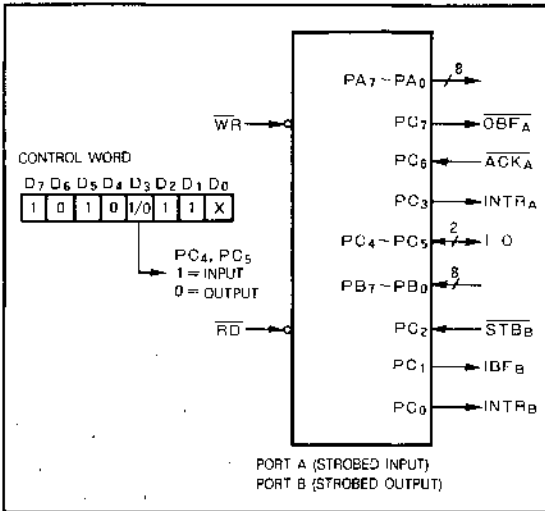

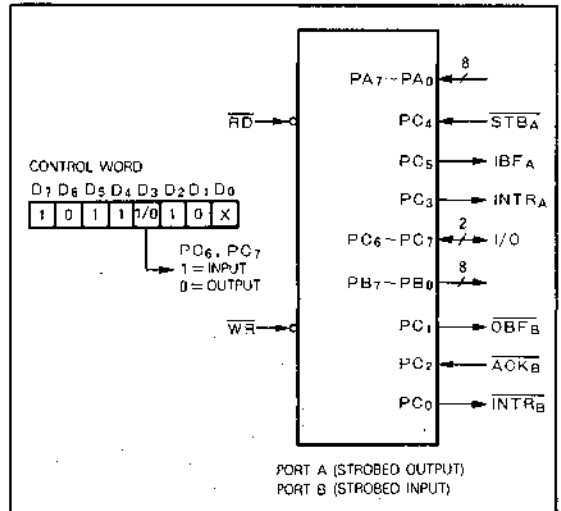

Fig. 8 Mode 1 port A and port B I/O example

8

PROGRAMMABLE PERIPHERAL INTERFACE

3. Mode 2 (Strobed Bidirectional Bus Input/Output)

Mode 2 can provide bidirectional operations, using one 8-bit bus for communicating with terminal units. Mode 2 is only valid with group A and uses one 8-bit bidirectional bus port (port A) and a 5-bit control port (high-order five bits of port C). The bus port (port A) has two internal registers, one for input and the other for output. On the other hand, the control port (port C) is used for communicating control signals and bus-status signals. These control signals are similar to mode 1 and can also be used to control interruption of the CPU. When group A is programmed as mode 2, group B can be programmed independently as mode 0 or mode 1. When group A is in mode 2, the following five control signals can be used.

OBF (Output Buffer Full Flag Output)

The OBF output will go low-level to indicate that the CPU has sent data to the internal register of port A. This signal lets the terminal units know that the data is ready for transfer from the CPU. When this occurs, port A remains in the floating (high-impedance) state.

ACK (Acknowledge Input)

A low-level ACK input will cause the data of the internal register to be transferred to port A. For a high-level ACK input, the output buffer will be in the floating (high-impedance) state.

STB (Strobed Input)

When the STB input is low-level, the data from terminal units will be held in the internal register; and the data will be sent to the system data bus with an RD signal to the PPI.

IBF (Input Buffer Full Flag Output)

When data from terminal units is held on the internal register, IBF will be high level.

INTR (Interrupt Request Output)

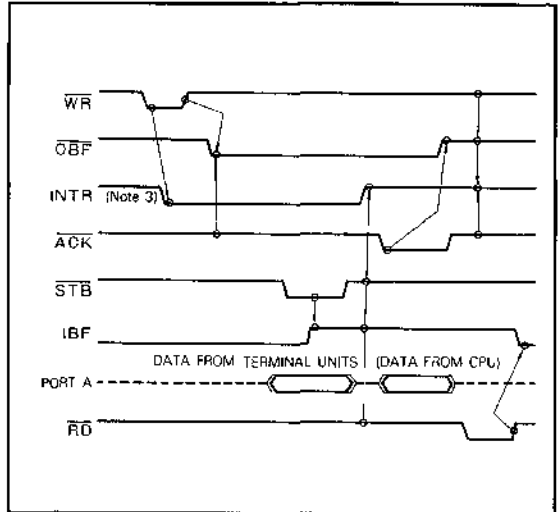

This output is used to interrupt the CPU and its operations the same as in mode 1. There are two interrupt enable flags that correspond to INTE_A for mode 1 output and mode 1 input.

INTE₁ is used in generating INTR signals in combination with OBF and ACK. INTE₁ is controlled by bit setting of PC₆.

INTE₂ is used in generating INTR signals in combination with IBF and STB. INTE₂ is controlled by bit setting of PC₄.

Fig. 9 shows the timing diagram of mode 2, and Fig. 10 is an example of mode 2 operation.

Fig. 9 Mode 2 timing diagram

Note 3: $INTR = IBF \cdot MASK \cdot STB \cdot RD + OBF \cdot MASK \cdot ACK \cdot WR$

Fig. 10 An example of mode 2 operation

PROGRAMMABLE PERIPHERAL INTERFACE

4. Control Signal Read

In mode 1 or mode 2 when using port C as a control port, by CPU execution of an IN instruction, each control signal and bus status from port C can be read.

5. Control Word Tables

Control word formats and operation details for mode 0, mode 1, mode 2 and set/reset control of port C are given in Tables 3, 4, 5 and 6, respectively.

Circuit Examples for Applications

1. Mode 0

An example of a circuit for an application using mode 0 is shown in Fig. 11.

Fig. 11 Circuit example for an application using mode 0.

In this example, the PPI is in mode 0, and the control word should be 10010000 (90₁₆).

```
MVI    A, 90#
OUT    03#
```

The PPI will be initialized by executing the above two instructions.

Then, for example, to read data from port A and to output data to port B and C, the following three instructions can be used.

```
IN     00# CPU A register ← Port A
OUT    01# Port B ← A register
OUT    02# Port C ← A register
```

After setting the mode each port operates as a normal port.

After setting the mode, as shown in Fig. 11, to read data from port A, to output to port B, and to set the first bit of port C "1", the following four instructions can be used.

```
IN     00# CPU A register ← Port A
OUT    01# Port B ← A register
MVI    A, 01# Bit-setting control word for PC0
OUT    03# Outputting to control address
        (CS = "0", A1 = A0 = "1")
```

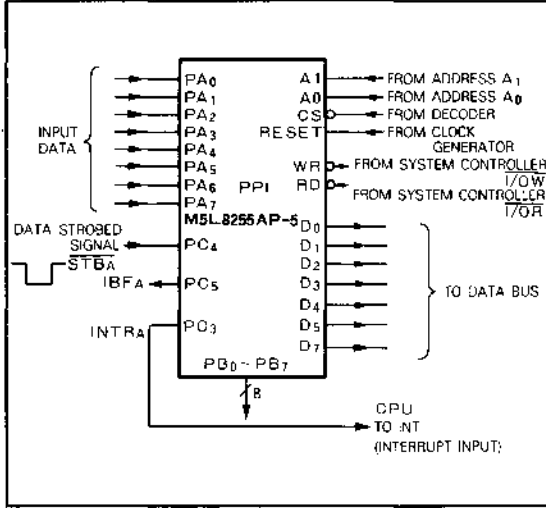

The other bits of port C, in this case, are unknown.

PROGRAMMABLE PERIPHERAL INTERFACE

2. Mode 1

An example of a circuit for an application using mode 1 is shown in Fig. 12.

Fig. 12 A circuit for an application using mode 1

Transferring data from a terminal unit to port A and sending a strobe signal to PC₄ will hold the data in the internal latch of the PPI, and PC₅ (IBF input buffer full flag) is set to "1". If a bit-set of PC₄ has been executed in advance, the CPU can be interrupted by the INTR signal of PC₃ when the input data is latched in the PPI. In this way, port A becomes an interrupting port; and at the same time, port B can select its mode independently.

The actual program for the circuit of Fig. 12 is as follows:

```

MVI A, B0 # Control word is 10110000, port A
             is the mode 1 input and the others
             are output.
OUT 03 #   Outputting to the control address
MVI A, 09 # PC4 bit-set 00001001
OUT 03 #   Outputting to the control address
EI        Interrupt enable
HLT      Halt
    
```

If the data has been set in a terminal unit, and the strobe signal has been input; then the data will be latched in port A and the CPU INT goes high-level. In the case of Fig. 11, this is followed by outputting instruction RST 7 from the system controller as an interrupt command. Then a jump to 0038₁₆ is executed to continue the program as follows:

```

003816 DI
      IN 00 # CPU register A ← Port A
             PC3 interrupt signal becomes
             low-level

RET
    
```

PROGRAMMABLE PERIPHERAL INTERFACE

3. Mode 2

An example of a circuit for an application using mode 2 is shown in Fig. 13.

In Fig. 13, the data bus of the slave system is connected with the corresponding PPI port A bit of the master station. The input port consists of a three-state buffer and gate B which allow the slave CPU to read flag outputs (IBF, OBF) of the PPI as data.

When the following instruction is executed in this example, the action is as described:

I N 0 1 # (reading in from 01₁₆ input port)

The data which is made up of the least significant bit (D₀), the OBF (output buffer full flag output) and the next least significant bit (D₁) of the IBF (input buffer full flag output) will be read into the slave CPU.

When the following instruction is executed, the action is as described:

I N 0 0 # (reading in from 00₁₆ input port)

ACK (PC₆) of the PPI becomes low-level by gate C, and the contents of the port A output latch will be read into the slave CPU.

When the following instruction is executed, the action is as described:

O U T 0 0 # (writing out to 00₁₆ output port)

STB (PC₄) of the PPI becomes low-level by gate D, then the contents of the slave CPU register A will be written into the port A input latch of the PPI.

Actual operations are as follows:

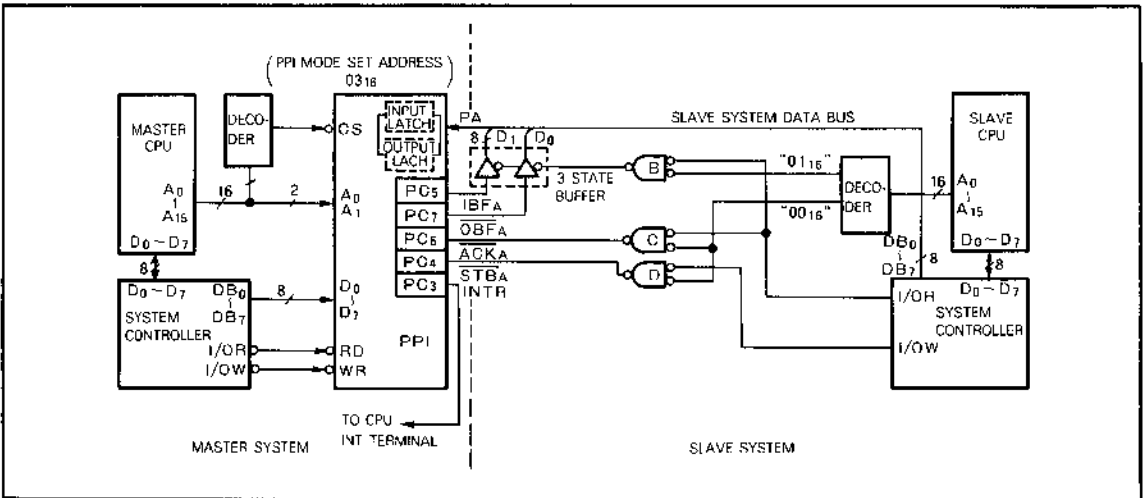

1. PPI is set in mode 2 by the master CPU (03 address).
2. The master CPU writes the data, which is transferred to the slave CPU, into port A of the PPI (in turn, OBF becomes low-level).
3. The slave CPU continues to read the state of flags (OBF and IBF) as data, while OBF is high-level (i.e. no data from the master CPU).

4. When the slave CPU senses that OBF has become low-level, the slave CPU starts to read the data from 00₁₆ (which is the input address for the preceding data) which is in the output latch of port A (in turn, OBF returns to high-level).
5. During this period, the master CPU reads the status flags (reading in from 02 of port C) and checks the states of both the bit 7 (OBF) and bit 5 (IBF). If OBF is low-level, it indicates that the slave CPU has not yet received the data; so the master does not write new data. If OBF is high-level, the master CPU writes the next data.
6. When data is to be transferred to the master CPU, the contents of the slave CPU A register will be transmitted to the port input latch of the PPI. The slave CPU transfers the data to address 00₁₆ (in turn, the IBF becomes high-level).
7. The master CPU transfers data to port C and then checks the status flag. If the input latch contains data from the slave CPU, which is indicated by IBF having a high-level output, the data is read from port A (00₁₆) (in turn, the IBF returns to low-level).
8. The slave CPU reads the status flag from 02₁₆ to determine if IBF has returned to low-level. If it has not, new data will not be written as long as IBF is high-level.
9. In this way, data can be exchanged. Since there are two sets of independent registers, input latch and output latch, used by port A of the PPI, it is not necessary to alternate input/output transfers.

A program which has operating functions as described above, is explained as follows.

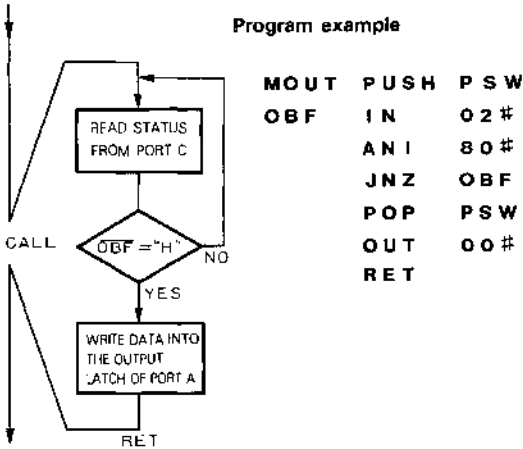

The operation, in mode 2, for group A of the PPI is considered here.

Fig. 13 A circuit for an application using mode 2

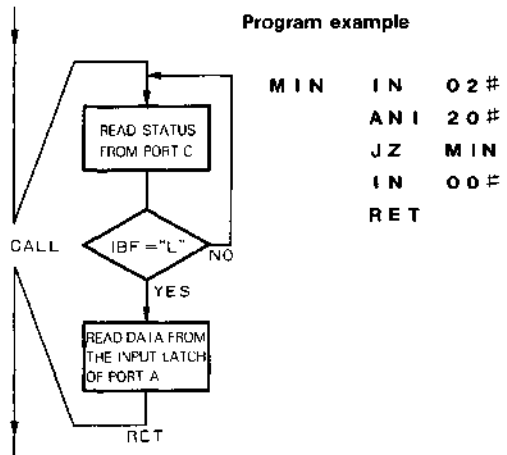

PROGRAMMABLE PERIPHERAL INTERFACE

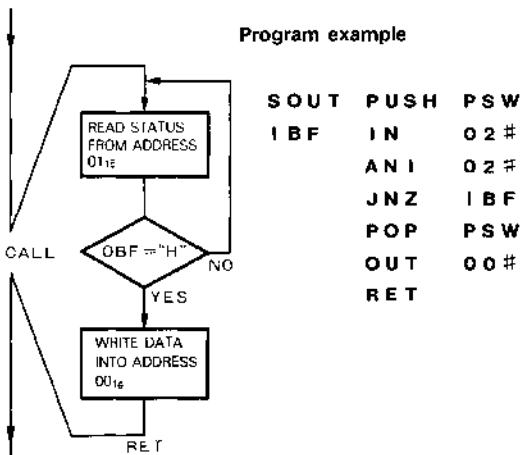

1. Master CPU subroutine for transmitting data to the slave CPU.

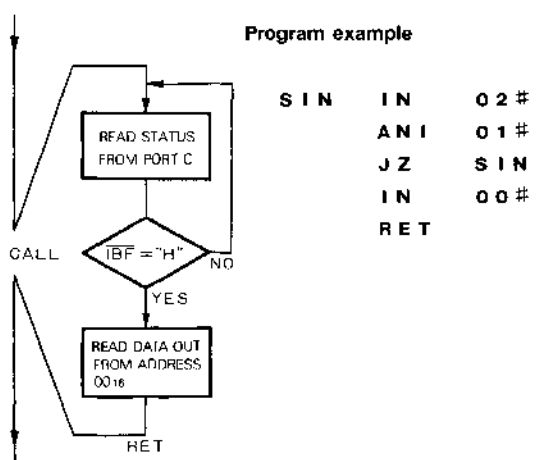

2. Subroutine for receiving data from the slave CPU.

3. Slave CPU subroutine for transmitting data to the master CPU.

4. Subroutine for receiving data from the master CPU.

PROGRAMMABLE PERIPHERAL INTERFACE

4. Address Decoding

Address decoding with multiple PPI units is shown in Figs. 14 and 15. These are functionally equal.

The same address data is output to both the upper and lower 8-bit address bus with the execution of IN and OUT instructions by the CPU.

Fig. 14 PPI address decoding (case 1)

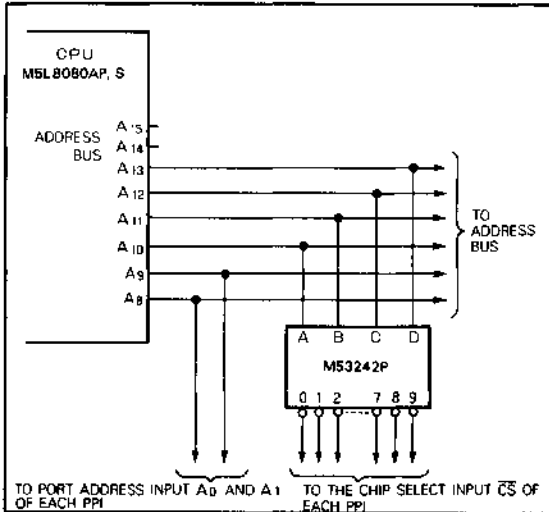

Fig. 15 PPI address decoding (case 2)

5. PPI Initialization

It is advisable to reset the PPI with a system initial reset and to select the mode at the beginning of a system program. The initial state of the PPI used as an output port is shown in Fig. 16.

Fig. 16 PPI initialization

Note 14: Period of reset pulse must be at least 50μs during or after power on. Subsequent reset pulse can be 500ns minimum.

PROGRAMMABLE DMA CONTROLLER

DESCRIPTION

The M5L8257P-5 is a programmable, 4-channel direct memory access (DMA) controller. It is produced using the N-channel silicon-gate ED-MOS process and is specifically designed to simplify data transfer at high speeds for micro-computer systems. The LSI operates on a single 5V power supply.

FEATURES

- 4-channel DMA controller
- Single 5V power supply
- Single TTL clock
- Priority DMA request logic
- Channel-masking function
- Terminal count and Modulo 128 outputs
- Compatible with the MELPS 8 microprocessor series
- Pin connection and electrical characteristics compatible with Intel's type 8257-5 programmable DMA controller

APPLICATIONS

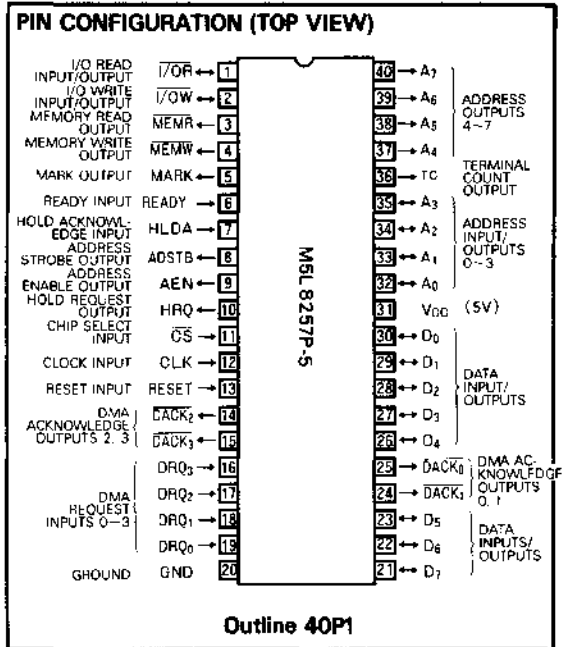

- DMA control of peripheral equipment such as floppy disks and CRT terminals that require high-speed data transfer.

FUNCTION

The M5L8257P-5 controller is used in combination with the M5L8212P 8-bit input/output port in 8-bit micro-computer systems.

It consists of a channel section to acknowledge DMA requests, control logic to exchange commands and data with the CPU, read/write logic, and registers to hold transfer addresses and count the number of bytes to be transferred.

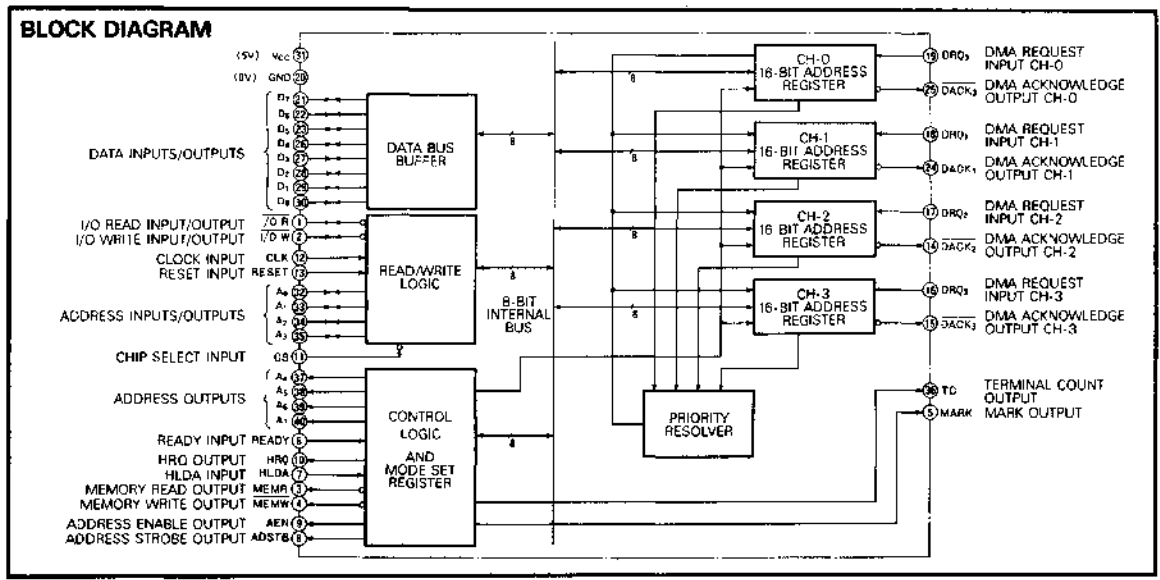

When a DMA request is made to an unmasked channel from the peripherals after setting of the transfer mode, transfer-start address and the number of transferred bytes for the registers, the M5L8257P-5 issues a priority request

Outline 40P1

for the use of the bus to the CPU. On receiving an HLDA signal from the CPU, it sends a DMA acknowledge signal to the channel with the highest priority, starting DMA operation.

During DMA operation, the contents of the high-order 8 bits of the transfer memory address are transmitted to the M5L8212P address-latch device through pins D₀~D₇. The contents of the low-order 8 bits are transmitted through pins A₀~A₇. After address transmission, DMA transfer can be started by dispatching read and write signals to the memories and peripherals.

PROGRAMMABLE DMA CONTROLLER

OPERATION

Data-Bus Buffer

This three-state, bidirectional, 8-bit buffer interfaces the M5L 8257P-5 to the CPU for data transfer. During a DMA cycle the upper 8 bits of the DMA address are output to the M5L 8212P latch device through this buffer.

I/O Read Input/Output ($\overline{I/OR}$)

When the M5L 8257P-5 is in slave-mode operation, this threestate, bidirectional pin serves for inputting and reads the upper/lower bytes of the 8-bit status register or 16-bit DMA address register and the high/low order bytes of the terminal counter.

In the master mode, the pin gives control output and is used to obtain data from a peripheral equipment during the DMA write cycle.

I/O Write Input/Output ($\overline{I/OW}$)

This pin is also of the three-state bidirectional type. When the M5L 8257P-5 is in slave-mode operation, it serves for inputting and loads the contents of the data bus on the upper/lower bytes of the 8-bit status register or 16-bit DMA address register and the upper/lower bytes of the terminal counter.

Clock Input (CLK)

This pin generates internal timing for the M5L 8257P-5 and is connected to the $\phi_{2(TTL)}$ output of the M5L 8224P-5 clock generator.

Reset Input (RESET)

This asynchronous input clears all registers and control lines inside the M5L 8257P-5.

Address Inputs/Outputs ($A_0 \sim A_3$)

The four bits of these input/output pins are bidirectional. When the M5L 8257P-5 is in slave-mode operation, serve to input and address the internal registers. In the case of master operation, they output the low-order 4 bits of the 16-bit memory address.

Chip-Select Input (CS)

This pin is active on a low-level. It enables the IORD and IOWR signals output from the CPU, when the M5L 8257P-5 is in slave-mode operation.

In the master mode, it is disabled to prevent the chip from selecting itself while performing the DMA function.

Address Inputs/Outputs ($A_4 \sim A_7$)

These four address lines are three-state outputs which constitute bits 4 through 7 of the memory address generated by the M5L 8257P-5 during all DMA cycles.

Ready Input (READY)

This asynchronous input is used to extend the memory read and write cycles in the M5L 8257P-5 with wait states if the selected memory requires longer cycles.

Hold Request Output (HRQ)

This output requests control of the system bus. HRQ will normally be applied to the HOLD input on the CPU.

Hold Acknowledge Input (HLDA)

This input from the CPU indicates that the system bus is controlled by the M5L 8257P-5.

Memory Read Output (MEMR)

This active-low three-state output is used to read data from the addressed memory location during DMA read cycles.

Memory Write Output (MEMW)

This active-low three-state output is used to write data into the addressed memory location during DMA write cycles.

Address Strobe Output (ADSTB)

This output strobes the most significant byte of the memory address into the M5L 8212P 8-bit input/output port through the data bus.

Address Enable Output (AEN)

This signal is used to disable the system data bus and system control bus by means of the bus enable pin on the M5L 8228P system controller. It may also be used to inhibit non-DMA devices from responding during DMA cycles.

Terminal Count Output (TC)

This output signal notifies that the present DMA cycle is the last cycle for this data block.

Mark Output (MARK)

This signal notifies that the DMA transfer cycle for each channel is the 128th cycle since the previous MARK output.

DMA Request Inputs (DRQ0~DRQ3)

These independent, asynchronous channel-request inputs are used to secure use of the DMA cycle for the peripherals.

DMA Acknowledge Outputs ($\overline{DACK0} \sim \overline{DACK3}$)

These active-low outputs indicate that the peripheral equipment connected to the channel in question can execute the DMA cycle.

PROGRAMMABLE DMA CONTROLLER

Register Initialization

Two 16-bit registers are provided for each of the 4 channels.

● **DMA Address register**

● **Terminal count register**

The DMA transfer starting address, number of transferred bytes, and DMA mode are written for each channel in 2 steps using the 8-bit data bus. The lower-order and upper-order bytes are automatically indicated by the first-last flipflop for the writing and reading in 2 continuous steps.

The DMA mode (read, write, or verify) is indicated by the upper 2 bits of the terminal count register. The read mode refers to the operation of peripheral devices reading data out of memory. The write mode refers to data from peripheral devices being written into memory. The verify mode sends neither the read nor the write signals and performs a data check at the peripheral device.

In addition to the above-mentioned registers, there is a mode set register and a status register.

● **Mode set register (write only)**

● **Status Register (read only)**

The upper-order 4-bits of the mode set register are used to select the added function, as described in Table 1. The lower-order 4-bits are mask kits for each channel. When set to 1, DMA requests are allowed. When the reset signal is input, all bits of the mode set and status registers are reset and DMA is inhibited for all channels. Therefore, to execute DMA operations, registers must first be initialized. An example of such an initialization is shown below.

MODESET:

- MVI A, ADDL
- OUT 00#: Channel 0 lower-order address
- MVI A, ADDH
- OUT 00#: Channel 0 upper-order address
- MVI A, TCL
- OUT 01#: Channel 0 terminal count lower-order
- OUT 01#: Channel 0 terminal count upper-order
- MVI A, XX
- OUT 08#: Mode set register

As can be seen from the above example, until the contents of the address register and terminal count register become valid, the enable bit of the mode set register must not be set. This prevents memory contents from being destroyed by improper DRQ signals from peripheral devices.

DMA Operation Description

When a DMA request signal is received at the DRQ pin from a peripheral device after register initialization for a channel that is not masked, the M5L8257P-5 outputs a hold request signal to the CPU to begin DMA operation (S₁).

The CPU, upon receipt of the HRQ signal, outputs the HLDA signal which reserves capture of the bus after it has executed the present instruction to place this system in the hold state.

When the M5L8257P receives the HLDA signal, an internal priority determining circuit selects the channel with the highest priority for the beginning of data transfer (S₀).

Upon the next S₁ state, the address signal is sent. The lower-order 8-bits and the upper-order 8-bits are sent by means of the A₀~A₇ and D₀~D₇ pins respectively, latched into the M5L8212P and output at pins A₈~A₁₅. Simultaneous with this, the AEN signal is output to prohibit the selection of a device not capable of DMA.

In the S₂ state, the read, extended write, and DACK signals are output and data transferred from memory or a peripheral device appears on the data bus.

In the S₃ state, the write signal required to write data to the bus is output. At this time if the remaining number of bytes to be transferred from the presently selected channel has reached 0, the terminal count (TC) signal is output. Simultaneously with this, after each 128-byte data transfer a mark signal is output as required. In addition, in this state the READY pin is sampled and, if low, the wait state (S_w) is entered. This is used to perform DMA with slow access memory devices. In the verify mode, READY input is ignored.

8

PROGRAMMABLE DMA CONTROLLER

In the S₄ state, the DRQ and HLDA pins are sampled at the end of a transferred byte as the address signal, control signals, and $\overline{\text{DACK}}$ signal are held to determine if transfer will continue.

As described above, transfer of 1 byte requires a minimum of 4 states for execution. For example, if a 2MHz clock input is used, the maximum transfer rate is 500k byte/s.

Fig. 1 DMA Operation state transition diagram

Memory Mapped I/O

When using memory mapped I/O, it is necessary to change the connections for the control signals.

Fig. 2 Memory mapped I/O

Also, the read mode and write mode specifications for setting the mode of the terminal count are reversed.

PROGRAMMABLE DMA CONTROLLER

Table 1 Internal Registers of the M5L8257P

Mode setting (for write only)	—	1	0	0	0	0	AL	TCS	EW	RP	EN3	EN2	EN1	EN0
Status (for read only)	—	1	0	0	0	0	0	0	0	UP	TC3	TC2	TC1	TC0

A₀~A₁₅ : Addresses of the memories for which DMA will be carried out from now on. In initialization, DMA start addresses must be written.
 C₀~C₁₃ : Terminal counts in this IC (the number of remaining transfer bytes minus 1)
 Rd, Wr : Used for DMA-mode setting by the following convention:

Rd	Wr	Mode to be set
0	0	DMA verify
0	1	DMA read
1	0	DMA write
1	1	Prohibition

AL : Automatic load mode. When this bit has been set, contents of the channel 3 register are written, as are, on the channel 2 register when channel 2 DMA transfer comes to an end. This mode allows quick, automatic chaining operations without intervention of the software.
 EW : Extended write signal mode. When this bit has been set, write signals can be transmitted in advance to memories and peripheral equipment requiring long access time.
 TCS : Terminal count stop. When a DMA transfer process is complete, with terminal-count output, the channel-enable mask of that channel is reset, prohibiting subsequent DMA cycles.
 RP : Rotating priority mode. The setting of this mode allows the priority order to be rotated by each byte transfer.

Channel used for the present data transfer	CH-0	CH-1	CH-2	CH-3
Priority list for the next cycle	1	CH-1	CH-2	CH-3
	2	CH-2	CH-3	CH-0
	3	CH-3	CH-0	CH-1
	4	CH-0	CH-1	CH-2

EN0~EN3 : Channel-enable mask. This mask prohibits or allows the DMA request.
 UP : Update flag. This is set when register contents are transferred in an automatic load mode from channel 3 to channel 2.
 TC0~TC3 : Terminal-count status flags. At the time of terminal-count output, the flag corresponding to the channel is set.
 F/L : First/last flip-flop. This is toggled when program and register-read operations for each channel are finished, and specifies whether the next program or read operation is to be for the upper bytes or the lower bytes. This means that write and read operations for each register must be carried out for a set of lower and higher bytes.

PROGRAMMABLE DMA CONTROLLER

APPLICATION EXAMPLE

PROGRAMMABLE INTERRUPT CONTROLLER

DESCRIPTION

The M5L8259AP is a programmable LSI for interrupt control. It is fabricated using N-channel silicon-gate ED-MOS technology and is designed to be used easily in connection with an M5L8080AP, M5L8085AP or M5L8086S.

FEATURES

- Single 5V power supply
- CALL instruction to the CPU is generated automatically
- Priority, interrupt mask and vectored address for each interrupt request input are programmable
- Up to 64 levels of interrupt requests can be controlled by cascading with M5L8259AP
- Polling functions
- TTL compatible
- Interchangeable with Intel's P8259A in pin configuration and electrical characteristics.

APPLICATIONS

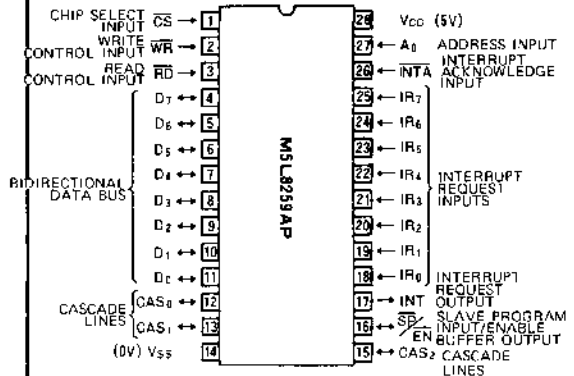

- The M5L8259AP can be used as an interrupt controller for CPUs M5L8080AP, M5L8085AP and M5L8086S

FUNCTIONS

The M5L8259AP is a device specifically designed for use in real time, interrupt driven microcomputer systems. It manages eight levels of request and has built-in features for expandability to other M5L8259AP's.

The priority and interrupt mask can be changed or re-configured at any time by the main program.

PIN CONFIGURATION (TOP VIEW)

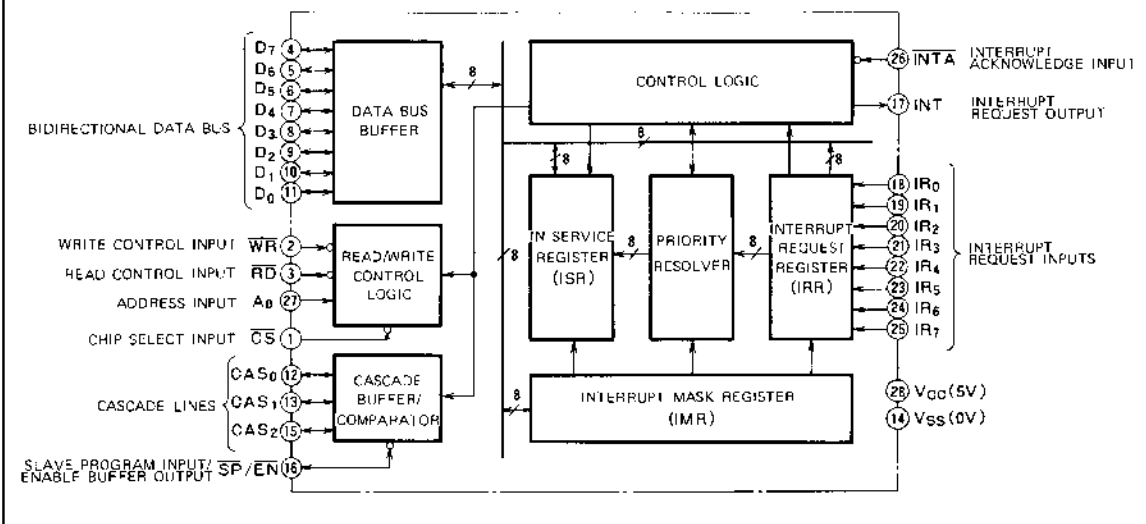

Outline 28P4

When an interrupt is generated because of an interrupt request at 1 of the pins, the M5L8259AP based on the mask and priority will output an INT to the CPU. After that, when an \overline{INTA} signal is received from the CPU or the system controller, a CALL instruction and a programmed vector address is released onto the data bus.

8

BLOCK DIAGRAM

PROGRAMMABLE INTERRUPT CONTROLLER

PIN DESCRIPTION

Symbol	Pin name	Input or output	Functional significance
\overline{CS}	Chip select input	Input	This input is active at low-level, but may be at high-level during interrupt request input and interrupt processing.
\overline{WR}	Write control input	Input	Command write control input from the CPU.
\overline{RD}	Read control input	Input	Data read control input for the CPU.
$D_7 \sim D_0$	Bidirectional data bus	Input/output	Data and commands are transmitted through this bidirectional data bus to and from the CPU.
$CAS_2 \sim CAS_0$	Cascade lines	Input/output	These pins are outputs for a master and inputs for a slave. And these pins of the master will be able to address each individual slave. The master will enable the corresponding slave to release the device routine address during bytes 2 and 3 of \overline{INTA} .
$\overline{SP/EN}$	Slave program input/Enable buffer output	Input/output	SP: In normal mode, a master is designated when $\overline{SP/EN}=1$ and a slave is designated when $\overline{SP/EN}=0$. EN: In the buffered mode, whenever the M5L8259AP's data bus output is enabled, its $\overline{SP/EN}$ pin will go low.
INT	Interrupt request output	Output	This pin goes high whenever a valid interrupt is asserted.
$IR_7 \sim IR_0$	Interrupt request input	Input	The asynchronous interrupt inputs are active at high-level. The interrupt mask and priority of each interrupt input can be changed at any time. When using edge triggered mode, the rising edge (low to high) of the interrupt request and the high-level must be held until the first \overline{INTA} . For level triggered mode, the high-level must be held until the first \overline{INTA} .
\overline{INTA}	Interrupt acknowledge input	Input	When an interrupt acknowledge (\overline{INTA}) from the CPU is received, the M5L8259AP releases a CALL instruction or vectored address onto the data bus.
A_0	A_0 address input	Input	This pin is normally connected to one of the address lines and acts in conjunction with the \overline{CS} , \overline{WR} and \overline{RD} when writing commands or reading status registers.

OPERATION

The M5L8259AP is interfaced with a standard system bus as shown in Fig. 1 and operates as an interrupt controller.

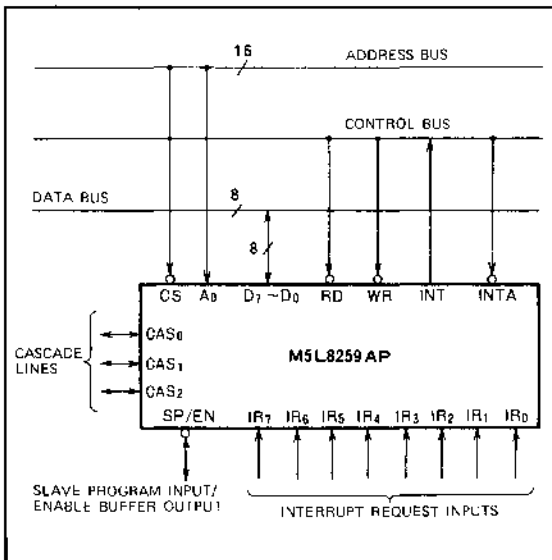

Fig. 1 The M5L8259AP interfaces to standard system bus.

Table 1 M5L8259AP basic operation

A_0	D_4	D_3	\overline{RD}	\overline{WR}	\overline{CS}	Input operation (read)
0			0	1	0	IRR, ISR or interrupting level → data bus
1			0	1	0	IMR → Data bus
						Output operation (write)
0	0	0	1	0	0	Data bus → OCW2
0	0	1	1	0	0	Data bus → OCW3
0	1	X	1	0	0	Data bus → ICW1
1	X	X	1	0	0	Data bus → OCW1, ICW2, ICW3, ICW4
						Disable function
X	X	X	1	1	0	Data bus → High impedance
X	X	X	X	X	1	Data bus → High impedance

PROGRAMMABLE INTERRUPT CONTROLLER

Interrupt Sequence

1. When the CPU is an M5L8080AP or M5L8085AP:
 - (1) When one or more of the interrupt request inputs are raised high, the corresponding IRR bit(s) for the high-level inputs will be set.
 - (2) Mask state and priority levels are considered and, if appropriate, the M5L8259AP sends an INT signal to the CPU.
 - (3) The acknowledgement of the CPU to the INT signal, the CPU issues an \overline{INTA} pulse to the M5L8259AP.
 - (4) The ISR bit corresponding to the interrupt request input is set upon receiving an \overline{INTA} from the CPU, and the corresponding IRR bit is reset. A CALL instruction is released onto the data bus.
 - (5) A CALL is a 3-byte instruction, so additional \overline{INTA} pulses are issued to the M5L8259AP from the CPU.
 - (6) These two \overline{INTA} pulses allow the M5L8259AP to release the program address onto the data bus. The low-order 8-bit vectored address is released at the second \overline{INTA} pulse and the high-order 8-bit vectored address is released at the third \overline{INTA} pulse.
 - (7) This completes the 3-byte CALL instruction and the interrupt routine will be serviced. The ISR bit is reset at the end of the third \overline{INTA} pulse in the AEOI mode. In the other modes the ISR bit is not reset until an EOI command is issued.
2. When the CPU is an M5L8086S:
 - (1) When one or more of the interrupt request inputs are raised high, the corresponding IRR bit(s) for the high-level inputs will be set.
 - (2) Mask state and priority levels are considered and if appropriated, the M5L8259AP sends an INT signal to the CPU.
 - (3) As an acknowledgement to the INT signal, the CPU issues an \overline{INTA} pulse to the M5L8259AP.
 - (4) The ISR bit corresponding to the interrupt request input is set upon receiving the first \overline{INTA} pulse from the CPU, and the corresponding IRR bit is reset. The M5L8259AP does not drive the data bus, and the data bus goes to high-impedance state.
 - (5) When the second \overline{INTA} pulse is issued from the CPU an 8-bit pointer is released onto the data bus.
 - (6) This completes the interrupt cycle and the interrupt routine will be serviced. The ISR bit is reset at the end of the second \overline{INTA} pulse in the AEOI mode. In the other modes the ISR bit is not reset until an EOI command is issued from the CPU.

The interrupt request input must be held at high-level until the first \overline{INTA} pulse is issued. If it is allowed to re-

turn to low-level before the first \overline{INTA} pulse is issued, an interrupt request in IR₇ is executed. However, in this case the ISR bit is not set.

Interrupt sequence outputs

1. When the CPU is a M5L8080AP or M5L8085AP:

A CALL instruction is released onto the data bus when the first \overline{INTA} pulse is issued. The low-order 8 bits of the vectored address are released when the second \overline{INTA} pulse is issued, and the high-order 8 bits are released when the third \overline{INTA} pulse is issued. The format of these three outputs is shown in Table 2.

Table 2 Formats of interrupt CALL instruction and vectored address

First \overline{INTA} pulse (CALL instruction)

D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀
1	1	0	0	1	1	0	1

Second \overline{INTA} pulse (low-order 8-bit of vectored address)

IR	Interval = 4							
	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀

PROGRAMMABLE INTERRUPT CONTROLLER

2. When the CPU is a M5L8086S:

The data bus goes to a high-impedance state when the first \overline{INTA} pulse is issued. Then the pointer $T_7 \sim T_0$ is released when the next \overline{INTA} pulse is issued. The content of the pointer $T_7 \sim T_0$ is shown in Table 3. The $T_2 \sim T_0$ are a binary code corresponding to the interrupt request level, $A_{10} \sim A_5$ are unused and ADI mode control is ignored.

Table 3 Contents of interrupt pointer

Second \overline{INTA} pulse (8-bit pointer)

	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀
IR ₇	T ₇	T ₆	T ₅	T ₄	T ₃	1	1	1
IR ₆	T ₇	T ₆	T ₅	T ₄	T ₃	1	1	0

IR ₁	T ₇	T ₆	T ₅	T ₄	T ₃	0	0	1
IR ₀	T ₇	T ₆	T ₅	T ₄	T ₃	0	0	0

Interrupt Request Register (IRR), In-service Register (ISR)

As interrupt requests are received at inputs IR₇~IR₀, the corresponding bits of IRR are set and as an interrupt request is serviced the corresponding bit of ISR is set. The IRR is used to store all the interrupt levels which are requesting service, and the ISR is used to store all the interrupt levels which are being serviced. The status of these two registers can be read. These two registers are connected through the priority resolver.

An interrupt request received by IR_n is acknowledged on the leading edge when in the edge triggered mode or it is acknowledged on the level when in the level triggered mode. After that an INT signal is released and the interrupt request signal is latched in the corresponding IRR bit if the high-level is held until the first \overline{INTA} pulse is issued. It is important to remember that the interrupt request signal must be held at high-level until the first \overline{INTA} pulse is issued.

The interrupt request latching in the IRR causes a signal to be sent to the priority resolver unless it is masked out. When the priority resolver receives the signals it selects the highest priority interrupt request latched in IRR. The ISR is set when the first \overline{INTA} pulse is issued while the corresponding bit of IRR is reset and the other bits of IRR are unaffected.

The bit of ISR that was set is not reset during the interrupt routine, but is reset at the end of the routine by the EOI command (end of interrupt) or by the last \overline{INTA} pulse in AEIOI mode.

Priority Resolver

The priority resolver examines all of the interrupt requests set in IRR to determine and selects the highest priority. The ISR bit corresponding to the selected (highest priority) request is set by the \overline{INTA} pulse.

Interrupt Mask Register (IMR)

The contents of the interrupt mask register are used to mask out (disable) interrupt requests of selected interrupt request pins. Each terminal is independently masked so that masking a high priority interrupt does not influence the lower or higher priority interrupts. Therefore the contents of IMR selectively enable reading.

Interrupt Request Output (INT)

The interrupt request output connects directly to the interrupt input of the CPU. The output level is compatible with the input level required for the CPUs.

Interrupt Acknowledge Input (\overline{INTA})

The CALL instruction and vectored address are released onto the data bus by the \overline{INTA} pulse.

Data Bus Buffer

The data bus buffer is a 3-state bidirectional data bus buffer that is used to interface with the system bus. Write commands to the M5L8259AP, CALL instructions, vectored addresses, status information, etc. are transferred through the data bus buffer.

Read/Write Control Logic

The read/write control logic is used to control functions such as receiving commands from the CPU and supplying status information to the data bus.

Chip Select (\overline{CS})

The M5L8259AP is selected (enabled) when \overline{CS} is at low-level, but during interrupt request input or interrupt processing it may be high-level.

Write Control Input (\overline{WR})

When \overline{WR} goes to low-level the M5L8259AP can then write.

Read Control Input (\overline{RD})

When \overline{RD} goes low status information in the internal register of the M5L8259AP can be read through the data bus.

Address Input (A_0)

The address input is normally connected with one of the address lines and is used along with \overline{WR} and \overline{RD} to control write commands and reading status information.

Cascade Buffer/Comparator

The cascade buffer/comparator stores or compares identification codes. The three cascade lines are output when the M5L8259AP is a master or input when it is a slave. The identification code on the cascade lines select it as master or slave.

PROGRAMMABLE INTERRUPT CONTROLLER

PROGRAMMING THE M5L8259AP

The M5L8259AP is programmed through the Initialization Command Word (ICW) and the operational command word (OCW). The following explains the functions of these two commands.

Initialization Command Words (ICWs)

The initialization command word is used for the initial setting of the M5L8259AP. There are 4 commands in this group and the following explains the details of these four commands.

ICW1

The meaning of the bits of ICW1 is explained in Fig. 3 along with the functions. ICW1 contains vectored address bits $A_7 \sim A_5$, a flag indicating whether interrupt input is edge triggered or level triggered, CALL address interval, whether a single M5L8259AP or the cascade mode is used, and whether ICW4 is required or not.

Whenever a command is issued with $A_0=0$ and $D_4=1$, this is interpreted as ICW1 and the following will automatically occur.

- (a) The interrupt mask register (IMR) is cleared.
- (b) The interrupt request input IR_7 is assigned the lowest priority.
- (c) The identification code for slave mode is set to 7.
- (d) The special mask mode is cleared and the status read is set to the interrupt request register (IRR).
- (e) When $IC4=0$ all bits in ICW4 are set to zero.

ICW2

ICW2 contains vectored address bits $A_{15} \sim A_8$ or interrupt type $T_7 \sim T_3$, and the format is shown in Fig. 3.

ICW3

When $SNGL=1$ it indicates that only a single M5L8259AP is used in the system, in which case ICW3 is not valid. When $SNGL=0$, ICW3 is valid and indicates cascade connections with other M5L8259AP devices. In the master mode, a "1" is set for each slave.

When the CPU is an M5L8080AP or M5L8085AP the CALL instruction is released from the master at the first \overline{INTA} pulse and the vectored address is released onto the data bus from the slave at the second and third \overline{INTA} pulses.

When the CPU is a M5L8086S the master and slave are in high-impedance at the same time and the pointer is released onto the data bus from the slave at the next \overline{INTA} pulse.

The master mode is specified when $\overline{SP/EM}$ pin is high-level or $BUF=1$ and $M/S=1$ in ICW4, and slave mode is specified when $\overline{SP/EM}$ pin is low-level or $BUF=1$ and $M/S=0$ in ICW4. In the slave mode, three bits $ID_2 \sim ID_0$ identify the slave. And then when the slave code released on the cascade lines from the master, matches the assigned ID code, the vectored address is released by it onto the data bus at the next \overline{INTA} pulse.

ICW4

Only when $IC4=1$ in ICW1 is ICW4 valid. Otherwise all bits are set to zero. When ICW4 is valid it specifies special fully nested mode, buffer mode master/slave, automatic EOI and microprocessor mode. The format of ICW4 is shown in Fig. 3.

PROGRAMMABLE INTERRUPT CONTROLLER

Fig. 3 Initialization command word format

PROGRAMMABLE INTERRUPT CONTROLLER

Operation Command Words (OCWs)

The operation command words are used to change the contents of IMR, the priority of interrupt request inputs and the special mask. After the ICW are programmed into the M5L8259AP, the device is ready to accept interrupt requests. There are three types of OCWs; explanation of each follows, and the format of OCWs is shown in Fig. 4.

OCW1

The meaning of the bits of OCW1 are explained in Fig. 4

along with their functions. Each bit of IMR can be independently changed (set or reset) by OCW1.

OCW2

The OCW2 is used for issuing EOI commands to the M5L8259AP and for changing the priority of the interrupt request inputs.

OCW3

The OCW3 is used for specifying special mask mode, poll mode and status register read.

Fig. 4 Operation command word format

PROGRAMMABLE INTERRUPT CONTROLLER

FUNCTION OF COMMAND

Interrupt masks

The mask register contains a mask for each individual interrupt request. These interrupt masks can be changed by programming using OCW1.

Special mask mode

When an interrupt request is acknowledged and the ISR bit corresponding to the interrupt request is not reset by EOI command (which means an interrupt service routine is executing) lower priority interrupt requests are ignored.

In special mask mode interrupt requests received at interrupt request inputs which are masked by OCW1 are disabled, but interrupts at all levels that are not masked are possible. This means that in the mask mode all level of interrupts are possible or individual inputs can be selectively programmed so all interrupts at the selected inputs are disabled. The masks are stored in IMR and special mask is set/reset by executing OCW3.

Buffered mode

The buffered mode will structure the M5L8259AP to send an enable signal on $\overline{SP/EN}$ to enable the data bus buffer, when the data bus requires the data bus buffer or when cascading mode is used. In this mode, when data bus output of the M5L8259AP is enabled, the $\overline{SP/EN}$ output becomes active. This allows the M5L8259AP to be programmed whether it is a master or a slave by software. The buffered mode is set/reset by executing ICW4.

Fully nested mode

The fully nested mode is the mode when no mode is specified and is the usual operational mode. In this mode, the priority of interrupt request terminals is fixed from the lowest IR_7 to the highest IR_0 . When an interrupt request is acknowledged the CALL instruction and vectored address are released onto the data bus. At the same time the ISR bit corresponding to the accepted interrupt request is set. This ISR bit remains set until it is reset by the input of an EOI command or until the trailing edge of last \overline{INTA} pulse in AEIOI mode. While an interrupt service routine is being executed, interrupt requests of same or lower priority are disabled while the bit of ISR remains set. The priorities can be changed by OCW2.

Special fully nested mode

The special fully nested mode will be used when cascading is used and this mode will be programmed to the master by ICW4. The special fully nested mode is the same as the fully nested mode with the following two exceptions.

1. When an interrupt from a certain slave is being serviced, this slave is not locked out from the master priority logic. Higher priority interrupts within the slave will be recognized by the master and the master will initiate an interrupt request to the CPU. In general in the

normal fully nested mode, a serviced slave is locked out from the master's priority, and so higher priority interrupts from the same slave are not serviced.

2. When an interrupt from a certain slave is being serviced the software must check ISR to determine if there are additional interrupts requests to be serviced. If the ISR bit is 0 the EOI command may be sent to the master too. But if it is not 0 the EOI command should not be sent to the master.

Poll mode

The poll mode is useful when the internal enable flip-flop of the microprocessor is reset, and interrupt input is disabled. Service to the device is achieved by a programmer initiative using a poll command. In the poll mode the M5L8259AP at the next \overline{RD} pulse puts 8 bits on the data bus which indicates whether there is an interrupt request and reads the priority level. The format of the information on the data bus is as shown below.

When $I=0$ (no interrupt request), $W_2 \sim W_0$ is 111. The poll is valid from \overline{WR} to \overline{RD} and interrupt is frozen. This mode can be used for processing common service routines for interrupts from more than one line and does not require any \overline{INTA} sequence. Poll command is issued by setting $P=1$ in OCW3.

End of interrupt (EOI) and specific EOI (SEOI)

An EOI command is required by the M5L8259AP to reset the ISR bit. So an EOI command must be issued to the M5L8259AP before returning from an interrupt service routine.

When AEIOI is selected in ICW4, the ISR bit can be reset at the trailing edge of the last \overline{INTA} pulse. When AEIOI is not selected the ISR bit is reset by the EOI command issued to the M5L8259AP before returning from an interrupt service routine. When programmed in the cascade mode the EOI command must be issued to the master once and to corresponding slave once.

There are two forms of EOI command, specific EOI and non-specific EOI. When the M5L8259AP is used in the fully nested mode, the ISR bit being serviced is reset by the EOI command. When the non-specific EOI is issued the M5L8259AP will automatically reset the highest ISR bit of those that are set. Other ISR bits are reset by a specific EOI and the bit to be reset is specified in the EOI by the program. The SEOI is useful in modes other than free nested

PROGRAMMABLE INTERRUPT CONTROLLER

mode. When the M5L8259AP is in special mask mode ISR bits masked in IMR are not reset by EOI. EOI and SEOI are selected when OCW2 is executed.

Automatic EOI (AEOI)

In the AEOI mode the M5L8259AP executes non-specific EOI command automatically at the trailing edge of the last \overline{INTA} pulse. The AEOI mode is not required within a single M5L8259AP, but it is useful when a nested multilevel interrupt structure is expected. When AEOI=1 in ICW4, the M5L8259AP is put in AEOI mode continuously until re-programmed in ICW4.

Automatic rotation

The automatic rotation mode is used in applications where many interrupt requests of the same level are expected such as multichannel communication systems. In this mode when an interrupt request is serviced, that request is assigned the lowest priority so that if there are other interrupt requests they will have higher priorities. This means that the next request on the interrupt request being serviced must wait until the other interrupt requests are serviced (worst case is waiting for all 7 of the other controllers to be serviced). The priority and serving status are rotated as shown in Fig. 5.

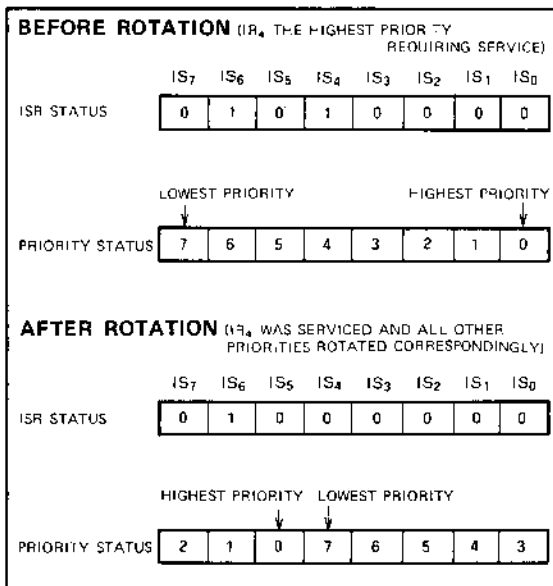

Fig. 5 An example of priority rotation

Automatic rotation mode is selected when R=1, EOI=1, SL=0 in OCW2. The internal priority status is changed by EOI or AEOI commands. The rotation priority A flip-flop is set by R=1, EOI=0 and SL=0 which is useful when the M5L8259AP is used in the AEOI mode.

Specific rotation

Specific rotation gives the user versatile capabilities in interrupt controlled operations. It serves in those applications in which a specific device's interrupt priority must be altered. As opposed to automatic rotation which automatically sets priorities, specific rotation is completely user controlled. That is, the user selects the interrupt level that is to receive lowest or highest priority. Priority changes can be executed during an EOI command.

Level triggered mode/Edge triggered mode

Selection of level or edge triggered mode of the M5L8259AP is made by ICW1. When using edge triggered mode not only is a transition from low to high required, but the high-level must be held until the first \overline{INTA} . If the high-level is not held until the first \overline{INTA} , the interrupt request will be treated as if it were input on IR₇, except that the ISR bit is not set. When level triggered mode is used the functions are the same as edge triggered mode except that the transition from low to high is not required to trigger the interrupt request.

In the level triggered mode and using AEOI mode together, if the high-level is held too long the interrupt will occur immediately. To avoid this situation interrupts should be kept disabled until the end of the service routine or until the IR input returns low. In the edge triggered mode this type of mistake is not possible because the interrupt request is edge triggered.

Reading the M5L8259AP internal status

The contents of IRR and ISR can be read by the CPU with status read. When an OCW3 is issued to the M5L8259AP and an \overline{RD} pulse issued the contents of IRR or ISR can be released onto the data bus. A special command is not required to read the contents of IMR. The contents of IMR can be released onto the data bus by issuing an \overline{RD} pulse when A₀=1. There is no need to issue a read register command every time the IRR or ISR is to be read. Once a read register command is received by the M5L8259AP, it remains valid until it is changed. Remember that the programmer must issue a poll command every time to check whether there is an interrupt request and read the priority level. Polling overrides status read when P=1, RR=1 in OCW3.

PROGRAMMABLE INTERRUPT CONTROLLER

Cascading

The M5L8259AP can be interconnected in a system of one master with up to eight slaves to handle up to 64 priority levels. A system of three units that can be used with the M5L8080AP or M5L8085AP is shown in Fig. 6.

The master can select a slave by outputting its identification code through the three cascade lines. The INT output of each slave is connected to the master interrupt request inputs. When an interrupt request of one of the slaves is to be serviced the master outputs the identification

code of the slave through the cascade lines, so the slave will release the vectored address on the next \overline{INTA} pulse.

The cascade lines of the master are normally low, and will contain the slave identification code from the trailing edge of the first \overline{INTA} pulse to the leading edge of the last \overline{INTA} pulse. The master and slave can be programmed to work in different modes. ICWs, and EOI commands must be issued twice: once for the master and once for the corresponding slave. Each \overline{CS} of the M5L8259AP requires an address decoder.

- Note 1 M5L8086S mode
 2 M5L8080AP/M5L8085AP mode
 3 M5L8086S mode is in high-impedance state, pointer is released during the next \overline{INTA} .
 When in single M5L8080AP/M5L8085AP mode, data is released by all \overline{INTA} s. When master, CALL instruction is released during the first \overline{INTA} , high impedance state during the second and third \overline{INTA} . When slave, high impedance state during the first \overline{INTA} , vectored address is released during the second and third \overline{INTA} .

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

DESCRIPTION

The M5L8279P-5 is a programmable keyboard and display interface device that is designed to be used in combination with an 8-bit microprocessor such as the Mitsubishi MELPS 8 CPUs. This device is fabricated with N-channel silicon-gate technology and is packed in a 40-pin DIL package. It needs only single 5V power supply.

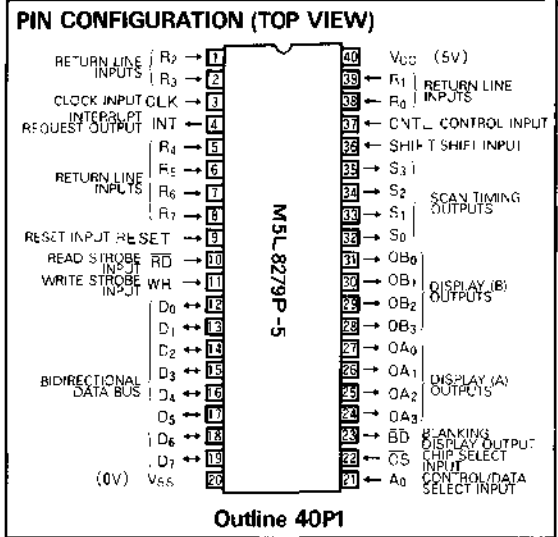

FEATURES

Parameter	M5L 8279P-5
Output enable time after read (max)	200ns
Output enable time after address (max)	250ns
Clock cycle time (min)	320ns

- Single 5V power supply
- Keyboard mode
- Sensor mode
- Strobed entry mode
- Internally provided key bounce protection circuit
- Programmable debounce time
- 2-key/N-key rollover
- 8-character keyboard FIFO
- Internally contained 16 × 8-bit display RAM
- Programmable right and left entry
- Interchangeable with Intel's 8279/8279-5 in pin configuration and electrical characteristics

APPLICATIONS

- Microcomputer I/O device
- 64 contact key input device for such items as electronic cash registers
- Dual 8- or single 16-alphanumeric display

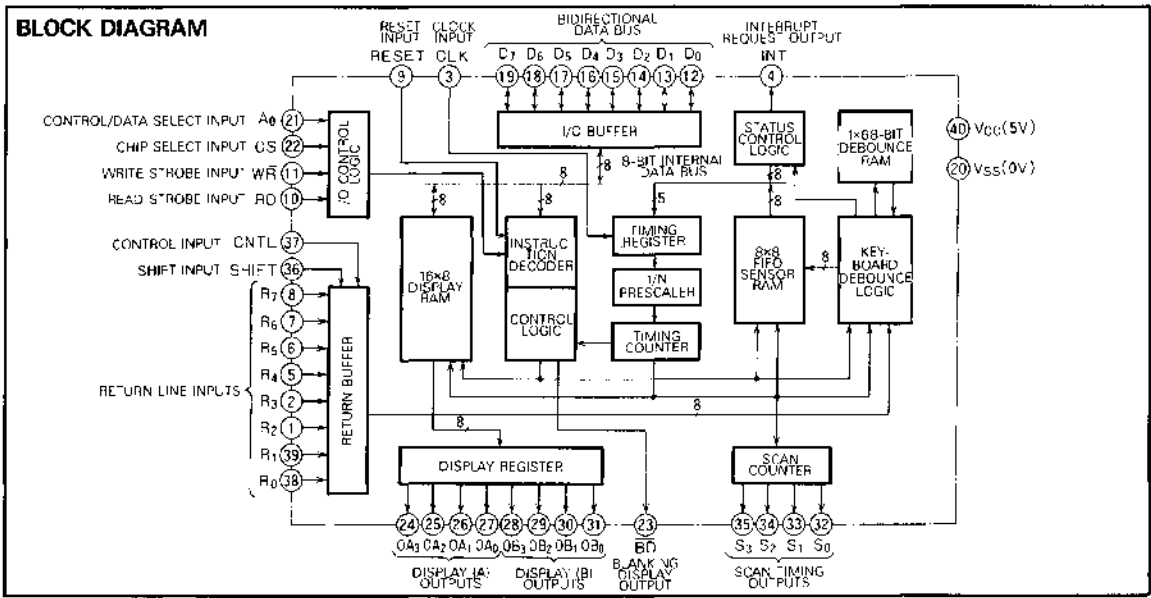

FUNCTION

The total chip, consisting of a keyboard interface and a display interface, can be programmed by eight 8-bit commands.

The keyboard portion is provided with a 64-bit key debounce buffer and an 8 × 8-bit FIFO. It operates in any one of the scanned keyboard mode, scanned sensor mode or strobed entry mode.

The display portion is provided with a 16 × 8-bit display RAM that can be organized into a dual 16 × 4 configuration. Also, an 8-digit display configuration is possible by means of programming.

8

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

PIN DISCRIPTON

Pin	Name	Input or output	Functions
D ₀ ~D ₇	Bidirectional data bus	In/out	All data and commands between the CPU and the chip are transferred through these lines
CLK	Clock input	In	Clock signal from the system which is used to generate internal timing.
RESET	Reset input	In	Resets the chip when this signal is high. After the reset it assumes 8-digit, left entry, encode display, and 2-key rollover mode, and the preset value of the clock becomes 31. The display RAM, however, is not cleared.
CS	Chip select input	In	Chip select is enabled when this signal is low.
A ₀	Control/data select input	In	When this signal is high, it indicates that the signals in and out are either command (in) or status (out). When low, it indicates they are data (in/out).
RD	Read strobe input	In	Functions to control data transfer to the data bus
WR	Write strobe input	In	Functions to control command/data transfer from the data bus
INT	Interrupt request output	Out	When there is any data in the FIFO during the keyboard mode or the strobed mode, this signal turns high-level so as to request interrupt to the CPU. It turns low each time data is read, but if any data remains in the FIFO it will turn high again and request interrupt to the CPU.
S ₀ ~S ₃	Scan timing outputs	Out	These signals are used to scan the key switch, the sensor matrix, or the display digit. They can be either decoded or encoded, but it requires an external decoder in the encode mode. Signals S ₀ ~S ₃ are all turned to low-level when RESET is high.
R ₀ ~R ₇	Return line inputs	In	These are the return lines which are connected with the scan lines through the keys or sensor switches, and are used for 8-bit input in the strobed entry mode. They are provided with internal pullups to maintain them high until a switch closure pulls one low. They become active at low-level.
SHIFT	Shift input	In	In the keyboard mode, the shift input becomes the second highest bit of the key input information and is stored in the FIFO. This input is ignored in the other modes. It is constantly kept at high level by an internal pull resistor.
CNTL	Control input	In	In the keyboard mode, the control input becomes the most significant bit of the key input information and is stored in the FIFO. The signal is active at high-level. In the strobed entry mode, it becomes the strobe signal and stores the return input data in the FIFO at the rising edge of the input. It affects nothing internal in the sensor mode. It is constantly kept at high-level by an internal pullup resistor.
OA ₀ ~OA ₃ OB ₀ ~OB ₃	Display (A) and (B) outputs	Out	These output ports can be used either as a dual 4-bit port or a single 8-bit port depending on an application, and the contents of the display RAM are output synchronizing with the scan timing signals. These two 4-bit ports may be blanked independently. Blanking may be activated with either high- or low-level signal by means of clear command.
BD	Blanking display output	Out	This signal is used in preventing overlapped display during digit switching. It also may be brought to low-level by display blanking command.

OPERATION

Of the three operating modes, the keyboard mode is the most common, and allows programmed 2-key lockout and N-key rollover. Encoded timing signals corresponding with key input are stored in the FIFO through the key-debounce logic, and the debouncing time of the key is also programmable. In the sensor mode, the contents of the 8 × 8 key contacts are constantly stored in the FIFO/sensor RAM, generating an interrupt signal to the CPU each time there is a change in the contents. In the strobed entry mode, the CNTL input signal is used as a strobe for storing the 8 return line inputs to the FIFO/sensor RAM.

The display portion is provided with a 16 × 8-bit display RAM that can be organized into a dual 16 × 4-bit configu-

ration. Also, an 8-digit display configuration is possible by means of programming. Input to the register can be performed by either left or right entry modes. In the auto increment mode, read and write can be carried out after designating the starting address only.

Both the keyboard and display sections are scanned by common scan timing signals that are derived from the basic clock pulse. This frequency-dividing ratio is changeable by means of programming. There are decode and encode modes for the scanning mode; timing signals that are decoded from the lower 2 bits of the scan counter are output in the decode mode, while the 4-bit binary output from the scan counter is decoded externally in the encode mode.

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

COMMAND DESCRIPTION

There are eight commands provided for programming the operating modes of the M5L8279P. These commands are sent on the data bus with the signal \overline{CS} in low-level and the signal A_0 in high-level and are stored in the M5L8279P at the rising edge of the signal \overline{WR} .

1. Mode Set Command

DD (Display mode set command)

- 0 0 8–8-bit character display—left entry
- 0 1 16–8-bit character display—left entry¹
- 1 0 8–8-bit character display—right entry
- 1 1 16–8-bit character display—right entry

KKK (Keyboard mode set command)

- 0 0 0 Encoded display keyboard mode — 2-key lockout¹
- 0 0 1 Decoded display keyboard mode — 2-key lockout
- 0 1 0 Encoded display keyboard mode — N-key rollover
- 0 1 1 Decoded display keyboard mode — N-key rollover
- 1 0 0 Encoded display, sensor mode
- 1 0 1 Decoded display, sensor mode
- 1 1 0 Encoded display, strobed entry mode
- 1 1 1 Decoded display, strobed entry mode

Note 1 : Default after reset.

2. Program Clock Command

The external clock is divided by the prescaler value P P P P P designated by this command to obtain the basic internal frequency.

When the internal clock is set to 100kHz, it will give a 5.1ms keyboard scan time and a 10.3ms debounce time. The prescale value that can be specified by P P P P P is from 2 to 31. In case P P P P P is 00000 or 00001, the prescale is set to 2. Default after a reset pulse is 31, but the prescale value is not cleared by the clear command.

3. Read FIFO Command

This command is used to specify that the following data readout ($CS \cdot \overline{A_0} \cdot RD$) is from the FIFO. As long as data is to be read from the FIFO, no additional commands are necessary.

AI and AAA are used only in the sensor mode. AAA designates the address of the FIFO to be read, and AI is the auto-increment flag. Turning AI to "1" makes the address automatically incremented after the second read operation. This auto-increment bit does not affect the auto-increment of the display RAM.

4. Read Display RAM Command

This command is used to specify that the following data readout ($CS \cdot \overline{A_0} \cdot RD$) is from the display RAM. As long as data is to be read from the display RAM, no additional commands are necessary.

The data AAAA is the value with which the display RAM read/write counter is set, and it specifies the address of the display RAM to be read or written next.

AI is the auto-increment flag. Turning AI to "1" makes the address automatically incremented after the second read/write operation. This auto-increment bit does not affect the auto-increment of FIFO readout in the sensor mode.

5. Write Display RAM Command

With this command, following display RAM read/write addressing is achieved without changing the data readout source (FIFO or display RAM). Meaning of AI and AAAA are identical with read display RAM command.

6. Display Write Inhibit/Blanking Command

The IW is a write inhibit bit to the display RAM that corresponds with the output A or B. Inhibit is activated by turning the IW "1".

The BL is used in blanking the out A or B. Blanking is activated by turning the BL "1". Setting both BL flags makes the signal \overline{BD} low so that it can be used in 8-bit display mode.

Resetting the flags makes all IW and BL turn "0".

7. Clear command

C_D: Clears the display RAM.

C _D	C _D	C _D	
0	X	X	No specific performance
1	0	X	Entire contents of the display RAM are turned "0".
1	1	0	The contents of the display RAM are turned 20H (00100000 = 0A ₃ 0A ₂ 0A ₁ 0A ₀ 0B ₃ 0B ₂ 0B ₁ 0B ₀).
1	1	1	Entire contents of the display RAM are turned "1".

8

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

C_F: Clears the status word and resets the interrupt signal (INT).

C_A: Clears the display RAM and the status word and resets the interrupt signal (INT).

Clearing condition of the display RAM is determined by the lower 2 bits of the C_D.

Clearing the display RAM needs a whole display scan cycle and causes the display-unavailable status (DU) in the status word to be "1". The display RAM is not accessible for the duration of a scan cycle (scan time for 16 digits), even if the display mode was in 8-digit display mode or a decoded mode.

As both C_F and C_A function to reset the internal key-debounce counter, the key input under counting is ignored, and the internal FIFO counter is reset to make the interrupt signal low-level.

C_A resets the internal timing counter, forcing S₀~S₃ to start from S₃S₂S₁S₀ = 0000 after the execution of the command.

8. End Interrupt/Error Mode Set Command

In the sensor matrix mode, an interrupt signal is generated at the beginning of the next key scan time to inhibit further writing to the FIFO when there is a change in the sensor switch, but execution of this command makes the interrupt signal released so as to allow writing to the FIFO.

When E is kept in "0", depression of any sensor makes the second highest bit of the status word "1". When E is kept in "1", the status is kept "0" all the time.

When E is programmed to "1" in the N-key rollover mode, the execution of this command makes the chip operate in special error mode, during which time depression of more than two keys in a key scan time causes an error and sets the second highest bit of the status word "1".

Status word

NNN: Indicates the number of characters in the FIFO during the keyboard and strobed entry modes.

F: Indicates that the FIFO is filled up with 8 characters.

The number of characters existing in the FIFO (0~8 characters) can be known by means of the bits NNN and F (FNNN = 0000~FNNN = 1000).

U: Underrun error flag
 This flag is set when a master CPU tries to read an empty FIFO.

O: Overrun error flag
 This flag is set when another character is strobed into a full FIFO.

The bits U and O cannot be cleared by status read. They will be cleared by the clear command.

S/E: Sensor closure/multiple error flag
 When "111EXXXX" is executed by turning E = 0, the bit S/E in the status word is set when there is at least one sensor closure.

When "111EXXXX" is executed by turning E = 1 (special error mode), the bit S/E is set when there are more than two key depressions made in a key scan time.

DU: Display unavailable
 This flag is set during a whole display scan cycle when a clear display command is executed, and announces that the display RAM is not accessible.

Note: It is necessary to execute the clear command (C_F=1) to reset the underrun, overrun, and special error flags.

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

CPU INTERFACE

1. Command Write

A command is written on the rising edge of the signal \overline{WR} with \overline{CS} low and A_0 high.

2. Data Write

Data is written to the display RAM on the rising edge of the signal \overline{WR} with \overline{CS} and A_0 low.

The address of the display RAM is also incremented on the rising edge of the signal \overline{WR} if AI is set for the display RAM.

3. Status Read

The status word is read when \overline{CS} and \overline{RD} are low and A_0 is high. The status word appears on the data bus as long as the signal \overline{RD} is low.

4. Data Read

Data is read from either the FIFO or the display RAM with $\overline{CS} = \overline{RD} = 0$ and $A_0 = 1$. The source of the data (FIFO or display RAM) is decided by the latest command (read display or read FIFO). The data read appears on the data bus as long as the signal \overline{RD} is low.

The trailing edge of the signal \overline{RD} increments the address of the FIFO or the display RAM when AI is set. After the reset, data will be read from the FIFO, however.

\overline{CS}	A_0	\overline{RD}	\overline{WR}	Operation
0	1	1	0	Command write
0	0	1	0	Data write
0	1	0	1	Status read
0	0	0	1	Data read
1	X	X	X	No operation

KEYBOARD INTERFACE

Keyboard interface is done by the scan timing signals ($S_0 \sim S_3$), the return line inputs ($R_0 \sim R_7$), the SHIFT and the CNTRL inputs.

In the decoded mode, the low order of two bits of the internal scan counter are decoded and come out on the timing pins ($S_0 \sim S_3$). In the encoded mode, the four binary bits of the scan counter are directly output on the timing pins, thus a 3-to-8 decoder must be employed to generate keyboard scan timing.

The return line inputs ($R_0 \sim R_7$), the SHIFT and the CNTRL inputs are pulled up high by internal pullup transistors until a switch closure pulls one low.

The internal key debounce logic works for a 64-key matrix that is obtained by combining the return line inputs with the scan timing.

For the keyboard interface, M5L8279P-5 has four distinctive modes that allow various kinds of applications. In the following explanation, a "key scan cycle" is the time needed to scan a 64-key matrix, and a "key debounce cycle" needs a duration of two "key scan" cycles. (In the decoded mode 32 keys, unlike 64 keys in the encoded mode, can be employed for a maximum key matrix due to the limit of timing signals. However, both the key scan cycle and the key debounce cycle are the same as in the encoded mode.)

1. 2-Key Lockout (Scanned Keyboard mode)

The detection of a new key closure resets the internal debounce counter and starts counting. At the end of a key debounce cycle, the key is checked and entered into the FIFO if it is still down. An entry in the FIFO sets the IRQ output high. If any other keys are depressed in a key debounce cycle, the internal key debounce counter is reset each time it encounters a new key. Thus only a single-key depression within a key debounce duration is accepted, but all keys are ignored when more than two keys are depressed at the same time.

Example 1: Accepting two successive key depressions

Note 2 : ↑ : Debounce counter reset;
 ↓ : Key input

Example 2: Overlapped depression of three keys

Note 3 : Only key 2 is acceptable.

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

2. N-Key Rollover (Scanned Keyboard Mode)

Each key depression is treated independently from all others so as to allow overlapped key depression. Detection of a new key depression makes the internal key debounce counter reset and start to count in a same manner as in the case of 2-key rollover. But, in N-key rollover, other key closures are entirely ignored within a key debounce cycle so that depression of any other keys would not reset the key debounce counter. In this way, overlapped key depression is allowed so as to enable the following key input:

The scanned key input signal does not always reflect the actual key depressing action, as the key matrix is scanned by the timing signal.

With N-key rollover, there is a mode provided with which error is caused when there are more than two key inputs in a key scan cycle, which can be programmed by using the end interrupt/error mode set command. In this mode (special error mode), recognition of the above error sets the IRQ signal to "1" and sets the bit S/E in the status word.

In case two key entries are made separately in more than a debounce cycle, there would be no problem, as key depression is clearly identified. And no problem exists for 2-key lockout, as the both keys are recognized invalid.

Example of error

3. Sensor Matrix Mode

The key debounce logic is disabled in this mode. As the image of the sensor switch is kept in the FIFO, any change in this status is reported to the CPU by means of the interrupt signal INT. Although a debounce circuit is not used in this mode, it has an advantage in that the CPU is able to know how long and when the sensor was depressed.

In the sensor matrix mode with the bit E = 0 of the end interrupt/error mode set command, the second most significant bit of the status word (S/E bit) is set to "1" when any sensor switch is depressed.

4. Strobe Mode

The data is entered into the FIFO from the return lines (R₀~R₇) at the rising edge of a CNTL pulse. The INT goes high while any data exists in the FIFO, in the same manner as in the keyboard mode. The key debounce circuit will not operate.

Formats of data entered into the FIFO in each of the above modes are described in the following:

Keyboard matrix

Sensor matrix mode

Strobe mode

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

DISPLAY INTERFACE

The display interface is done by eight display outputs (OA₀~OA₃, OB₀~OB₃), a blanking signal (\overline{BD}), and scan timing outputs (S₀~S₃).

The relation between the data bus and the display outputs is as shown below:

Clearing the display RAM is achieved by the reset signal (θ -pin) but requires the execution of the clear command.

The timing diagrams for both the encoded and decoded modes are shown below.

For the encoded mode, a 3-to-8 or 4-to-16 decoder is required, according to whether eight or sixteen digit display used.

(1) Encoded mode

(2) Decoded mode

Note 4 : Here P_w is 640μs if the internal clock frequency is set to 100kHz

Timing relations of S, \overline{BD} , and display outputs (OA₀~OA₃, OB₀~OB₃) are shown below:

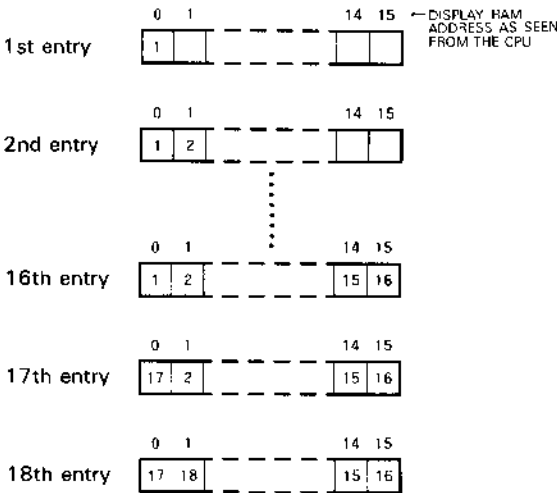

Note 5 Values of the output data shown in the slanted line areas are decided upon the clear command executed last to become the value of the display RAM after the reset. The values in the slanted areas after reset will go low. In the same manner, the values OA₀~OA₃, OB₀~OB₃ are dependent on the clear command executed last. When the both A and B are blanked, the signal \overline{BD} will be in low-level.

PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE

KEY ENTRY METHODS

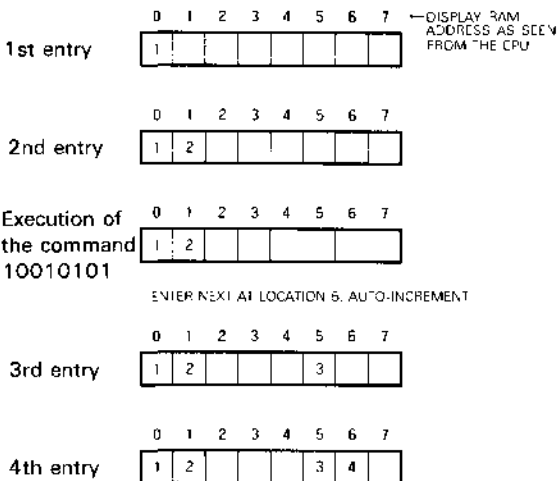

1. Left Entry

Address 0 in the display RAM corresponds to the leftmost position ($S_3S_2S_1S_0 = 0000$) of a display and address 15 (or address 7 in 8-character display) to the rightmost position ($S_3S_2S_1S_0 = 111$ or $S_2S_1S_0 = 111$). The 17th (9th) character is entered back into the leftmost position.

LEFT ENTRY

Auto-increment mode

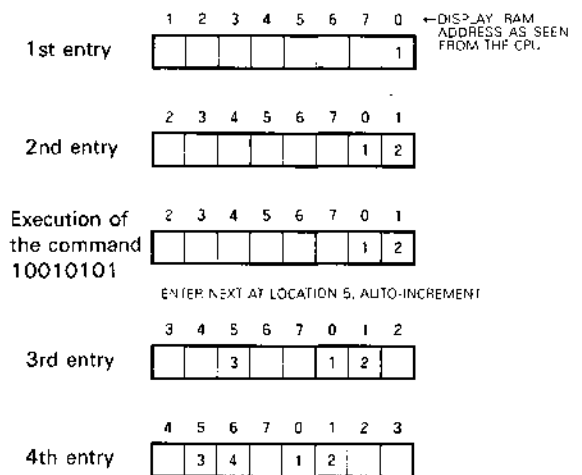

2. Right Entry

The first data is entered in the rightmost position ($S_3S_2S_1S_0 = 0000$ in 16-character display) of a display. From the next entry, the display is shifted left one character and the new data is placed in the rightmost position. A display position and a register address as viewed from the CPU change each each time and do not correspond.

Auto-increment mode

APPLICATION EXAMPLE

Note 8 When using an 8-bit character display of more than 9 digits for the decoder display, it is necessary to provide a separate decoder (for example 4-to-10 decoder, 4-to-16 decoder) and key scan 3-to-8 decoder. Only S₀, S₁ and S₂ may be used as inputs to the key scan 3-to-8 decoder.

9 Don't drive the keyboard decoder with the MSB of the scan line.

FLOPPY DISK FORMATTER/CONTROLLER

DESCRIPTION

The M5W1791-02P is a floppy disk formatter/controller device which accommodates single and double density formats. The device is designed for use with microprocessors or microcomputers. The device is fabricated with the N-channel silicon gate ED-MOS technology and is packaged in a 40-pin DIL package.

FEATURES

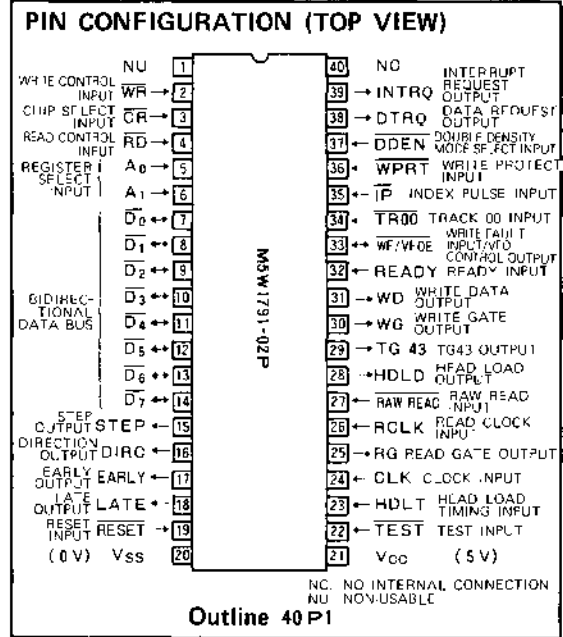

- Single 5V power supply
- Accommodate single and double density formats
 IBM 3740 single density format
 IBM system 34 double density format
- Selectable sector length (128,256,512 or 1024 bytes/sector)
- Side select compare
- Single/multiple sector read or write with automatic sector search
- Selectable track to track stepping time
- Write precompensation
- DMA or programmed data transfers
- Window extension
- Interchangeable with Western Digital's FD1791-02 in function except for V_{DD} power supply and pin configuration

APPLICATIONS

- Single or double density floppy disk drive formatter/controller
- 8-inch or mini floppy disk interface

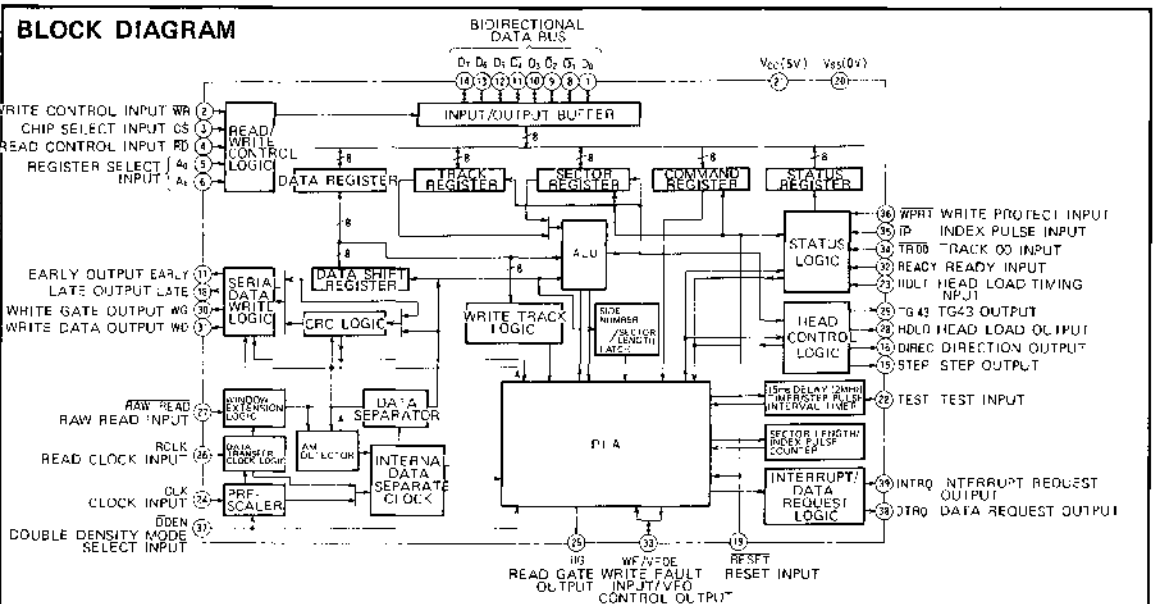

FUNCTION

The M5W1791-02P is a floppy disk formatter/controller that can be used with most microprocessor or microcom-

puter systems. The hardware of the M5W1791-02P consists of a floppy disk interface, a CPU interface and a PLA control logic. The total chip can be programmed by eleven 8-bit commands. The floppy disk interface portion performs the communication with the floppy disk drive under control of the PLA control logic. The CPU interface portion has five registers — command, data, status, track and sector register — and communicates with the CPU through the data bus. These functions are also controlled by the PLA.

8

FLOPPY DISK FORMATTER/CONTROLLER

PIN DESCRIPTION

Pin	Name	Input or output	Functions																				
NU	Non usable terminal		NU (pin 1) is internally connected to the back gate bias generator, so it must remain open.																				
NC	No internal connection		NC (pin 40) is not internally connected.																				
RESET	Reset input	Input	Reset input (Active low). The device is reset by this signal and automatically loads 0316 into the command register. The not-ready-status bit is also reset by this signal. When reset input is made to be high, the device executes restore command unless READY is active and the device loads 0116 to the sector register.																				
WR	Write control input	Input	Write signal from a master CPU (Active low).																				
CS	Chip select input	Input	Chip select (Active low).																				
RD	Read control input	Input	Read signal from a master CPU (Active low).																				
A ₀ , A ₁	Register select input	Input	Register select inputs. These inputs select the register under the control of the RD and WR. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>A₁</th> <th>A₀</th> <th>RD</th> <th>WR</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>STATUS REGISTER</td> <td>COMMAND REGISTER</td> </tr> <tr> <td>0</td> <td>1</td> <td>TRACK REGISTER</td> <td>TRACK REGISTER</td> </tr> <tr> <td>1</td> <td>0</td> <td>SECTOR REGISTER</td> <td>SECTOR REGISTER</td> </tr> <tr> <td>1</td> <td>1</td> <td>DATA REGISTER</td> <td>DATA REGISTER</td> </tr> </tbody> </table>	A ₁	A ₀	RD	WR	0	0	STATUS REGISTER	COMMAND REGISTER	0	1	TRACK REGISTER	TRACK REGISTER	1	0	SECTOR REGISTER	SECTOR REGISTER	1	1	DATA REGISTER	DATA REGISTER
A ₁	A ₀	RD	WR																				
0	0	STATUS REGISTER	COMMAND REGISTER																				
0	1	TRACK REGISTER	TRACK REGISTER																				
1	0	SECTOR REGISTER	SECTOR REGISTER																				
1	1	DATA REGISTER	DATA REGISTER																				
D ₀ ~D ₇	Bidirectional data bus	In/Out	Three state, inverted bidirectional data bus.																				
CLK	Clock input	Input	Clock input to generate internal timing, 2MHz for 8-inch drives, 1MHz for mini drives.																				
DTRQ	Data request output	Output	DTRQ is an open drain output, so pull up to V _{CC} by the 10k resistor. In the disk read mode, DTRQ indicates that data is assembled in the data register. In the disk write mode, it indicates that the data register is empty. DTRQ is reset by the read data or write data operation.																				
INTRQ	Interrupt request output	Output	INTRQ is also an open drain output, so pull up to V _{CC} by the 10k resistor. INTRQ becomes active at the completion of any command and is reset when the CPU reads the status or writes the command.																				
STEP	Step output	Output	Step pulse output (Active high)																				
DIRC	Direction output	Output	Direction output. High level means the head is stepping in and low level means the head is stepping out.																				
EARLY	Early output	Output	This signal is used for write precompensation. It indicates that the write data pulse should be shifted early.																				
LATE	Late output	Output	This signal is also used for write precompensation. It indicates that the write data pulse should be shifted late.																				
TEST	Test input	Input	This input is only used for test purposes, so user must tie it to V _{CC} or leave it open unless using voice coil actuated motors.																				
HOLT	Head load timing input	Input	When the device finds high level on this input, the device assumes that the head is engaged on the media. Active high.																				
RG	Read gate output	Output	This signal shows the external data separator that the synchfield is detected.																				

FLOPPY DISK FORMATTER/CONTROLLER

Pin	Name	Input or output	Functions
RCLK	Read clock input	Input	This signal is internally used for the data window. Phasing relation to raw read data is specified but polarity (RCLK high or low) is not important.
RAW READ	Raw read input	Input	This input signal from the drive shall be low for each recorded flux transit on
HOLD	Head load output	Output	This output signal controls the loading of the head of the drive. The head must be loaded on the media by this high-level output.
TG43	TG 43 output	Output	This output is valid only during disk read/write operation and it shows the position of the head. High level on this output indicates that the head is positioned between track 44 to 76
WG	Write gate output	Output	This signal becomes active before disk write operations are to occur.
WD	Write data output	Output	This signal consists of data bits and clock bits. It becomes active for every flux transition. Active high.
READY	Ready input	Input	This signal shows the device the drive is ready. In the disk read/write operation except for TYPE 1 command operation, low-level input terminates current operation and the device generates the INTRQ. In the TYPE 1 command operation, this signal is neglected. Not ready bit in the status register is the inverted form of this input.
WF/VFOE	Write fault input/ VFO enable output	In/Out	This is a bidirectional signal. It becomes write fault input when WG is active. In the disk write operation, low level signal on this input terminates the write operation and makes INTRQ active. This signal also appears in the status register as the write fault bit. When WG is inactive, this signal works as VFO enable output. $\overline{\text{VFOE}}$ output is also an open drain type, so pull it up to V_{CC} and never input active write fault signal while WG is inactive.
TR00	Track 00 input	Input	This signal indicates that the head is located on the track 00 to the device. Active low.
IP	Index pulse input	Input	This input indicates to the device that an index hole of the diskette has been encountered.
WPRT	Write protect input	Input	Low level signal on this input informs the device that the drive is in the write protected state. Before disk write operations, this signal is sampled and an active low signal will terminate the current command and set INTRQ. The write protect status bit in the status register is also set.
DDEN	Double density mode select input	Input	This input determines the device operation mode. When DDEN=0, double density mode is selected. When DDEN=1, single density mode is selected.

$t_{PLH} (\text{DIR-STP})$	Propagation time from direction to step	T_{DJR}	(Note 5)	12			μs

- Note: 1: The pulse of RAW READ may be any width if pulse's entirety within RCLK. When the pulse occurs in the RCLK window, RAW READ pulse width must be less than 300 ns for MFM mode and 600 ns for FM mode at CLK=2MHz. Times double for 1MHz.
 2: 100 ns pulse width is recommended for the RAW READ pulse in MFM mode.
 3: RAW READ cycle time $T_{C(RRH)}$ and WD cycle time $T_{C(WD)}$ is normally 2 μs in MFM and 4 μs in FM. Times double when CLK=1MHz.
 4: The polarity of RCLK during Raw READ is not important.
 5: When VFOF=1, RCLK must be low level.
 6: Times double when CLK=1MHz.

MELPS 86 MICROPROCESSORS

16-BIT PARALLEL MICROPROCESSOR

DESCRIPTION

The M5L8086S is a 16-bit parallel microprocessor fabricated using high-speed N-channel silicon-gate ED-MOS technology. It requires a single 5V power supply and has a maximum basic clock rate of 5MHz.

The M5L8086S is upward compatible, both in hardware and software, with the M5L8080AP, S and M5L8085AP, S therefore it can replace either of these devices. It has higher performance because of additional and more powerful operation and addressing functions and instructions.

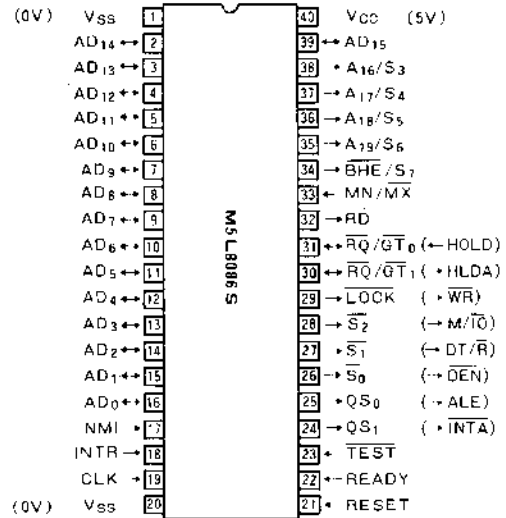

FEATURES

- Direct addressing: 1M byte
- Instruction set upward compatible with that of M5L-8080AP, S
- Enlarged powerful addressing: 24 modes
- On chip 16-bit registers: 14 registers
- Arithmetic operations include multiplication and division, signed or unsigned and 8-bit or 16-bit operands.
- Basic clock rate: 5MHz (max.)
- Multi-CPU functions
- Single 5V power supply
- Interchangeable with the Intel 8086 in pin configuration and electrical characteristics

APPLICATIONS

Central processing unit for 16-bit microcomputer and control units

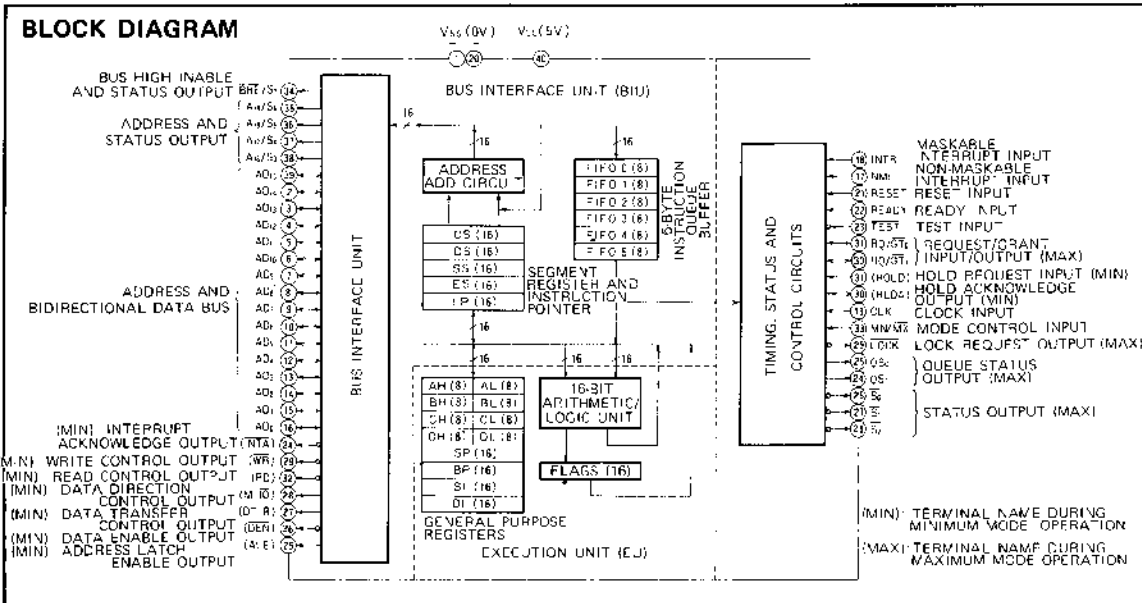

PIN CONFIGURATION (TOP VIEW)

() Terminal name during minimum mode operation
Outline 40 S I

FUNCTIONS

The M5L8086S has a minimum and maximum mode, which allows the composition to be selected to match the scale of the system in which it is used. The internal function consists of execution unit (EU) and bus interface unit (BIU). The BIU controls the 6-byte instruction queue, while generating addresses, and decodes instructions to be executed by the EU. Each unit operates asynchronously and can

16-BIT PARALLEL MICROPROCESSOR

access the instruction queue.

The pipeline architecture increased the throughput of the system. The ability to select 8-bit bytes or 16-bit words by using terminals A_0 and \overline{BHE} , allows more efficient use of memory. This along with a large direct addressable memory (up to 1 M bytes) makes it practical to process large complicated programs. Two kinds of external interrupt in-

put are provided. The INTR is a maskable interrupt input for the normal interrupt applications, while the NMI is a nonmaskable interrupt for the use of a higher priority interrupt such as power down. In addition to external interrupts, internal interrupts can be initiated by software with the overflow and so on.

PIN DESCRIPTIONS

Pins which have the same functions in minimum or maximum mode

Pin	Name	Input or Output	Functional description															
$AD_0 \sim AD_{15}$	Address and data bus	Input/output	$AD_0 \sim AD_{15}$ is used as both an address bus ($A_0 \sim A_{15}$) and a data bus ($D_0 \sim D_{15}$). Though time sharing it outputs addresses during T_1 state and outputs data during T_2, T_3, T_w, T_4 states.															
A_{19}/S_6 / A_{16}/S_3	Address and status	Output	The high-order 4 bits ($A_{16} \sim A_{19}$) and status ($S_3 \sim S_6$) are output using time sharing techniques. The address bits are output during T_1 state and data are output during T_2, T_3, T_w, T_4 states. The status bits S_3 and S_4 determine which segment register is used in the bus cycle as follows: <table style="margin-left: 20px;"> <tr> <td>S_4</td> <td>S_3</td> <td></td> </tr> <tr> <td>0</td> <td>0</td> <td>extra segment</td> </tr> <tr> <td>0</td> <td>1</td> <td>stack segment</td> </tr> <tr> <td>1</td> <td>0</td> <td>code segment or none</td> </tr> <tr> <td>1</td> <td>1</td> <td>data segment</td> </tr> </table> while S_5 shows the interrupt enable flag and starts the beginning of a clock cycle. Status bit S_6 is always 0.	S_4	S_3		0	0	extra segment	0	1	stack segment	1	0	code segment or none	1	1	data segment
S_4	S_3																	
0	0	extra segment																
0	1	stack segment																
1	0	code segment or none																
1	1	data segment																
\overline{BHE}/S_7	Bus high enable and status	Output	Bus high enable (\overline{BHE}) and status are output using time sharing techniques. Bus high enable is output during T_1 state and status is output during T_2, T_3, T_w, T_4 states. \overline{BHE} along with A_0 is used to select byte or word unit processing. The selection is as shown below: <table style="margin-left: 20px;"> <tr> <td>\overline{BHE}</td> <td>A_0</td> <td></td> </tr> <tr> <td>0</td> <td>0</td> <td>word processing (16 bits)</td> </tr> <tr> <td>0</td> <td>1</td> <td>high-order byte processing (8 bits)</td> </tr> <tr> <td>1</td> <td>0</td> <td>low-order byte processing (8 bits)</td> </tr> <tr> <td>1</td> <td>1</td> <td>undefined</td> </tr> </table> This pin goes to low-level during the first clock cycle of an interrupt acknowledge cycle. S_7 is a spare status bit.	\overline{BHE}	A_0		0	0	word processing (16 bits)	0	1	high-order byte processing (8 bits)	1	0	low-order byte processing (8 bits)	1	1	undefined
\overline{BHE}	A_0																	
0	0	word processing (16 bits)																
0	1	high-order byte processing (8 bits)																
1	0	low-order byte processing (8 bits)																
1	1	undefined																
\overline{RD}	Read control	Output	An active "L" signal indicates read timing from memory or an I/O port.															
READY	Ready	Input	Signal indicating data transfer to or from memory and I/O device. When the READY signal is at low level the CPU waits for the signal to go high level. When the signal is at high level the CPU ends the read or write.															
INTR	Maskable interrupt request	Input	This signal is sampled at the final clock cycle of each instruction for its level. Enable can be masked by software to inhibit interrupts. An interrupt vector of 256 types can be made using an M5L8259A.															
TEST	Test	Input	The CPU samples this pin while in the wait state. As the result of executing a WAIT instruction this pin is at high level. If the pin is still at high level when sampled the CPU continues to idle until it goes to low level and when that happens the CPU will resume operation.															
NMI	Non-maskable interrupt request	Input	This signal is sampled during the final clock cycle of an instruction execution cycle. It is used for urgent interrupts such as power down. A type 2 interrupt is generated by this signal.															
RESET	Reset	Input	This signal is used to initialize the CPU. When used it must be maintained at high level for 4 clock cycles to be effective.															
CLK	Clock	Input	This signal is used for internal clocking. It is normally attached to the clock output of a M5L8284P or similar device.															

16-BIT PARALLEL MICROPROCESSOR

Pin Description During Minimum Mode

Pin	Name	Input or output	Function description
$\overline{M}/\overline{IO}$	Data direction control	Output	This pin indicates whether the CPU is accessing memory or an I/O device at the time.
\overline{WR}	Write control	Output	This signal is used for timing when writing data to external memory or I/O device.
\overline{INTA}	Interrupt acknowledge	Output	This pin is used as the read strobe for the interrupt vector on the data bus during the interrupt acknowledge cycle.
\overline{ALE}	Address latch enable	Output	This signal is the output strobe from the CPU for write address. This is output using time sharing techniques to an external latch.
$\overline{DT}/\overline{R}$	Data transfer control	Output	This signal indicates the direction of data transfer between the data bus buffer and an external device.
\overline{DEN}	Data enable	Output	This signal enables the external data bus buffer.
\overline{HOLD}	Hold request	Input	When a hold request is received by the CPU it will enter the hold state and surrender control of the data bus at the end of the current instruction execution cycle.
\overline{HLDA}	Hold acknowledge	Output	This signal shows that the CPU bus accepted a hold request from a peripheral device and that control of the data bus has been surrendered to the peripheral device.

$t_{PLH}(\phi-\overline{DT})$	Propagation time, clock to data S/R control (Note 4)	TCLGLH	CL = 30pF			85	ns

- Note 4. Signal of M5L8284P is shown for reference.
5. Setup time required to be recognized at next clock.
6. Applies only to T₃ and wait states.
7. Applies only to T₃ status.

16-BIT PARALLEL MICROPROCESSOR

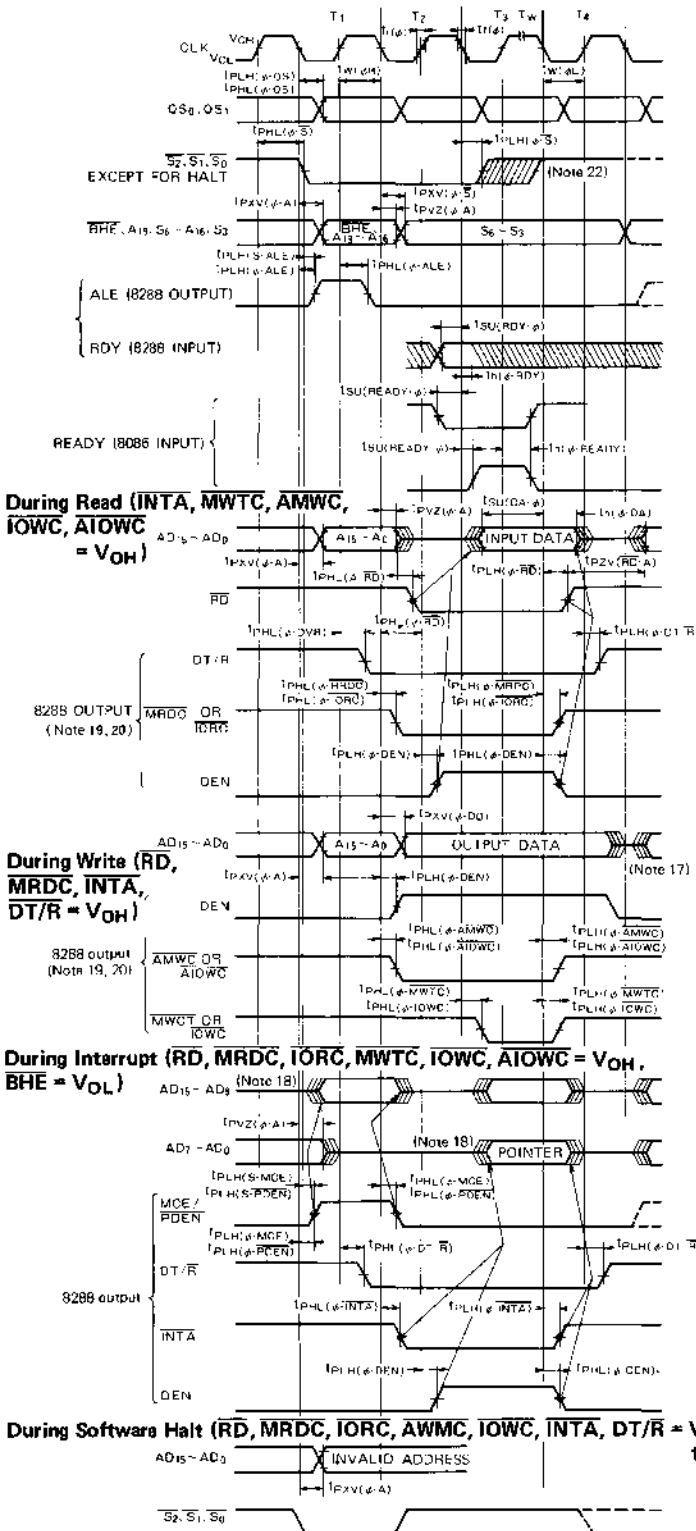

TIMING DIAGRAM (During Minimum Mode)

- Note 8: the center line indicates floating (high-impedance) state
- 9: Input signal is entered within the range of $V_{OH} \sim V_{OH}$ unless otherwise noted.
- 10: When the T_w state is entered the RDY signal is sampled near the end of T_2 , T_3 and T_w .
- 11: Only when the M5L8086S enters a hold acknowledge cycle does the local bus go to a floating state after a write cycle.
- 12: An interrupt cycle requires 2 clock cycles. The AD bus goes to a floating state during the second cycle of an interrupt.
- 13: Signals of the M5L8284P are shown for reference.
- 14: All timing signals are tested at 1.5V unless otherwise noted.

16-BIT PARALLEL MICROPROCESSOR

TIMING DIAGRAM (During Maximum Mode)

- Note 15: Input signals are entered within the range $V_{OL} \sim V_{OH}$ unless otherwise noted.
- 16: When the T_w state is entered the RDY signal is sampled near the end of T_1 , T_3 and T_w .
- 17: Only when the M5L8086S enters a hold acceptance cycle does the local bus go to a floating state after a write cycle. An interrupt cycle requires 2 cycles. The AD bus goes to a floating state during the second cycle of an interrupt.
- 18: Signals of the M5L8284P and M5L8286 are shown for reference.
- 19: The M5L8288 sends a command and a control signal soon after the CEN signal.
- 20: All timing signals are tested at 1.5V unless otherwise noted.
- 21: Status is invalid just before T_4 state.

16-BIT PARALLEL MICROPROCESSOR

TIMING DIAGRAM

Asynchronous Signal Recognition Timing

Note 23: Setup time required for being recognized in the next cycle.

Bus Lock Signal Timing (For Maximum Mode Only)

Request/Grant Sequence Timing (For Maximum Mode Only)

Hold Acknowledge Timing (For Minimum Mode Only)

- Note 24: S_7, S_6 and S_5 are changed to floating from the states of (1, 1, 1) at this edge
- 25: AD bus, \overline{RD} and \overline{LOCK} are changed to floating at this edge.
- 26: S_7, S_6 and S_5 of the other master are changed to floating from the states of (1, 1, 1) at this edge
- 27: AD bus, \overline{RD} and \overline{LOCK} of the other master are changed to floating at this edge
- 28: Bus is changed to floating at this edge.

Note 29: The number of clock and bus cycles depend on the number of times an instruction is repeated.
 The numbers shown are the number per loop and to determine the number of cycles the listed figures must be multiplied by the number of times the instruction is repeated.

Note 30: The preceding tables are summaries of details of the instructions of the M5L8086S. Basic instructions with variation are shown in brackets "[]" in the mnemonic column followed by the variations.

Instructions are from 1 to 6 bytes in length. Details of the first byte are given in the left half of the instruction code column, the second byte in the right half, the third byte below the first, the fourth byte below the second, the fifth byte below the third and the sixth byte below the fourth.

The hexadecimal column shows the value of the first byte of an instruction. When it has a single value the single value is shown. When it has a range of values, the range is shown.

SYMBOLS USED AND THEIR MEANING

Symbol	Contents	Symbol	Contents
Acc	Accumulator (AX, AL or AH)	LABEL	Label name
ADDR	Memory address	V	Inclusive OR
DATA	Immediate data (data which is part of the instruction)	∨	Exclusive OR
DISP	Displacement	∧	Logical AND
d	When d = 0 source is REG, destination is EA (R/M); When d = 1 source is EA (R/M), destination is REG	-	Subtraction
EA	Effective address	+	Addition
EA1, EA2	First effective address, second effective address	*	Multiplication
Port	I/O port	÷	Division
R1, R2	First register, second register	←	Direction of data transfer
SR	Segment register code	↔	Exchange of data
SEG	Segment register (CS, DS, SS and ES)	()	Contents of register or memory
W	When 0: byte processing When 1: word processing	V1:V2	Pair of register or data treated as one unit
L	Suffix indicating low-order 8 bits	×	Does not affect the flag or instruction
-H	Suffix indicating high-order 8 bits	⊙	Flag may be changed by the instruction
DEST	Transfer address (Destination address)	△	Flag is undefined after execution of the instruction
		FR	Flag register

ADDRESSING MODE AND REGISTER

1. Instruction Format

	SS	8
	DS	
Displacement + base register + index register BP + DI + D8 or D16 BX + SI + D8 or D16 BP + SI + D8 or D16 BX + DI + D8 or D16	SS	11
	DS	
	SS	12
	DS	

Note 32: When the segment override prefix is used, the segment register used (column 2) is changed to the segment register specified by $0001SR1110$ and 2 clock cycles must be added to the time (column 3) above.

3. Flag Register

Table 3 Flag code and name

- OF : overflow flag When an arithmetic overflow occurs, when 2 operands are exclusive ORed up to the high-order bit and the high-order bit is 1, OF is set.
 - DF : direction flag
 - IF : interrupt enable flag
 - TF : trap flag
 - SF : sign flag When the high-order bit is 1, SF is set.
 - ZF : zero flag When the result is zero, ZF is set.
 - AF : auxiliary flag When there is a borrow from the low-order 4 bits, AF is set.
 - PF : parity flag When the number of 1's in the low-order 8 bits is even, PF is set.
 - CF : carry flag When a carry is generated from the high-order bit, CF is set.
- OF, SF, ZF, AF, PF and CF are set/reset after the operation is completed

Note 33: Special symbols used only in the "Instruction set matrix" and the "Group Instruction Code List".

EA ← effective address (including register mode), REG ← register

- b : byte operation
- w : word operation
- : this code should not be used because the result and function are undefined
- a : accumulator
- d : direct address
- ea : calculation of EA
- ear : processing results of EA and REG are transferred to EA
- ear : (EA) ← (SR)
- i : immediate data
- ia : immediate data and accumulator
- id : indirect address
- is : immediate data in sign extended form
- l : segment is included in the jump
- m : memory
- rea : processing results of REG and EA are transferred to REG
- si : sign of 8 byte displacement is extended
- srea : (SR) ← (EA)
- v : variable
- z : z-bit
- ← : shows direction of transfer.

Note 34: The length of instructions varies from 1 byte (8 bits) to 6 bytes. The "Instruction Set Matrix" is ordered by the hexadecimal value of the first byte of the instruction. The instruction and its operands (an instruction may have no operand) are listed in mnemonic or symbolic form.

The group instructions (those instructions with different functions depending on bit D₃, D₄, D₅ in the second word of the instruction) are shown in the "Group Instruction Code List".

MITSUBISHI BIPOLAR DIGITAL ICs M5L8282P/M5L8283P

OCTAL LATCH

DESCRIPTION

The M5L8282P and M5L8283P are semiconductor integrated circuits consisting of sets of eight 3-state latches for use with various types of microprocessors.

FEATURES

- 3-state, high-fanout output
..... ($I_{OL} = 32\text{mA}$, $I_{OH} = -5\text{mA}$)
- Pin and electrical compatibility with the Intel 8282 and 8283

APPLICATION

Data latches for various microcomputer systems

FUNCTION

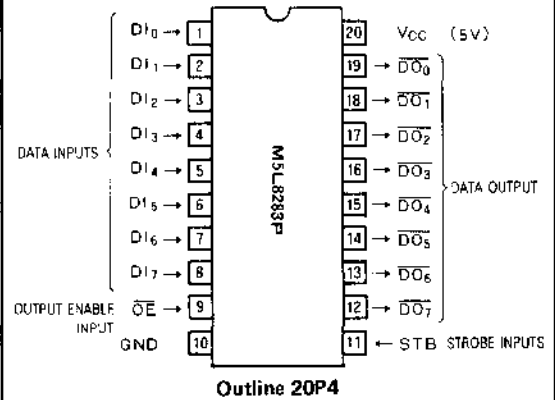

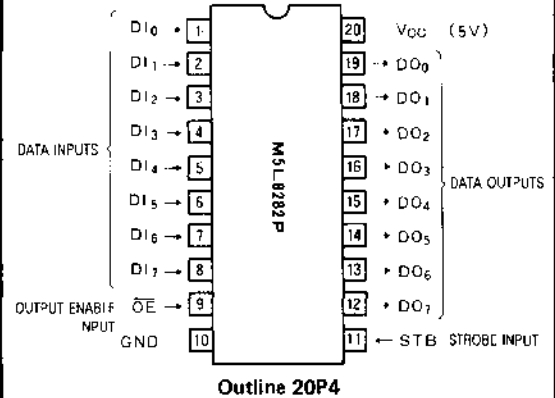

The M5L8282P and M5L8283P are latches with non-inverted and inverted outputs, respectively.

When the strobe input STB is high, the data inputs $DI_0 \sim DI_7$ are passed through the data outputs $\overline{DO}_0 \sim \overline{DO}_7$ (M5L8282P) or to the data outputs $DO_0 \sim DO_7$ (M5L8283P), changes in the $DI_0 \sim DI_7$ signals being reflected in the data outputs.

If the STB is changed from high to low, the data $DI_0 \sim DI_7$ just before the change is latched. If the DI data is changed while STB is low, this change is not reflected in the data outputs.

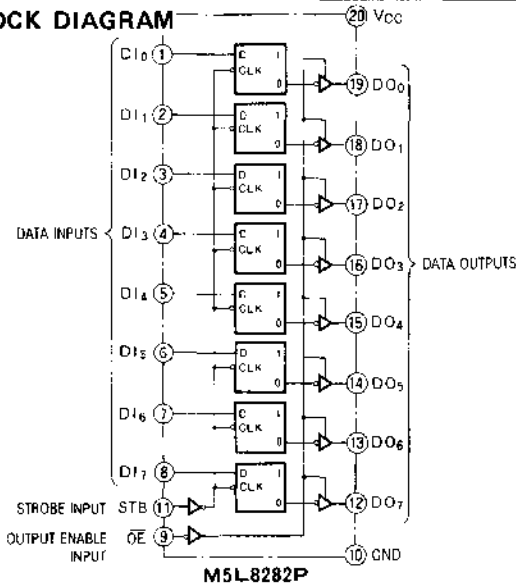

When OE is made high, all the data outputs go into the high-impedance state, the data latched prior to \overline{OE} going high being held.

PRECAUTIONS FOR USE

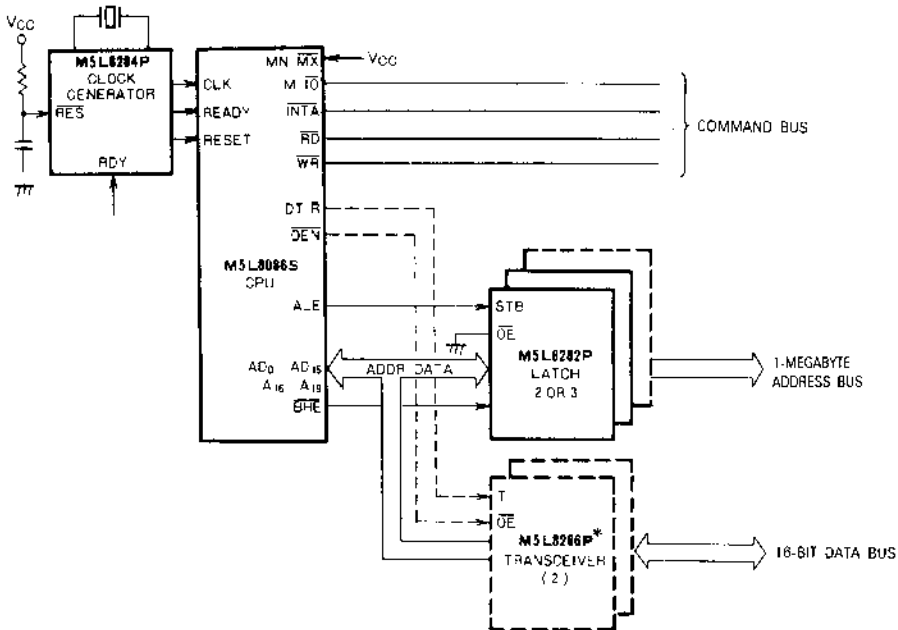

Care should be taken to accommodate the glitch that is generated when STB goes from low to high with the output low for the M5L8283P.

APPLICATION EXAMPLES

(1) Use in the maximum mode

(2) Use in the minimum mode

* : Option
 Required when the number of devices
 driving the bus increases

MITSUBISHI BIPOLAR DIGITAL ICs

M5L8284P

CLOCK GENERATOR AND DRIVER FOR 8086, 8088, 8089 PROCESSORS

DESCRIPTION

The M5L8284P is a semiconductor integrated circuit consisting of a clock generator for use with the 8086 and 8088 16-bit microprocessors.

It has a synchronous delay circuit and synchronous reset circuit capable of controlling two Multibus (Intel trade mark) circuits.

FEATURES

- Stable, crystal controlled output frequency
- Synchronous operation of several M5L8284Ps is possible
- External clock input
- By means of an external capacitor and resistance a power-on reset signal can be generated
- Pin and electrical compatibility with the Intel 8284

APPLICATION

Clock driver and generators for the 8086 or 8088.

FUNCTION

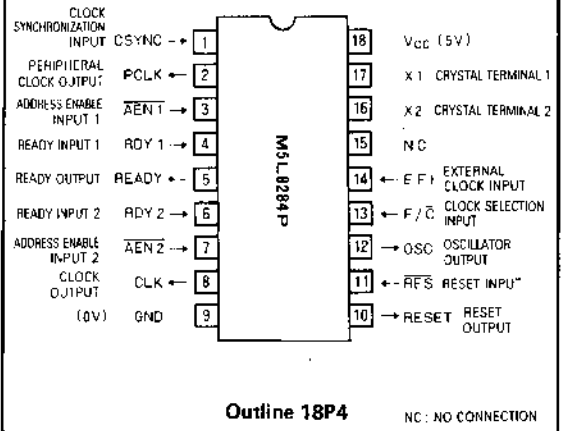

The M5L8284P is a clock generator/driver for the 8086, 8088 or 8089 processors.

Internally the crystal oscillator signal is divided by three to provide the clock output CLK, and by two to provide the peripheral clock output PCLK. In addition, a reset circuit and ready circuit are provided to ensure synchronization to the CLK signal.

The reset input \overline{RES} is used to generate the reset output \overline{RESET} as the CPU reset signal synced to the CLK signal. A Schmitt trigger circuit is used at the input side.

Thus, a reset signal can be output at power on by connecting a capacitor and resistor to the \overline{RES} input.

PIN CONFIGURATION (TOP VIEW)

The clock selection input F/\overline{C} can be used to select the crystal oscillator circuit output or an external clock input as the input for the divide by three circuit.

By using these pins, the M5L8284P output can be used to drive multiple M5L8284P devices.

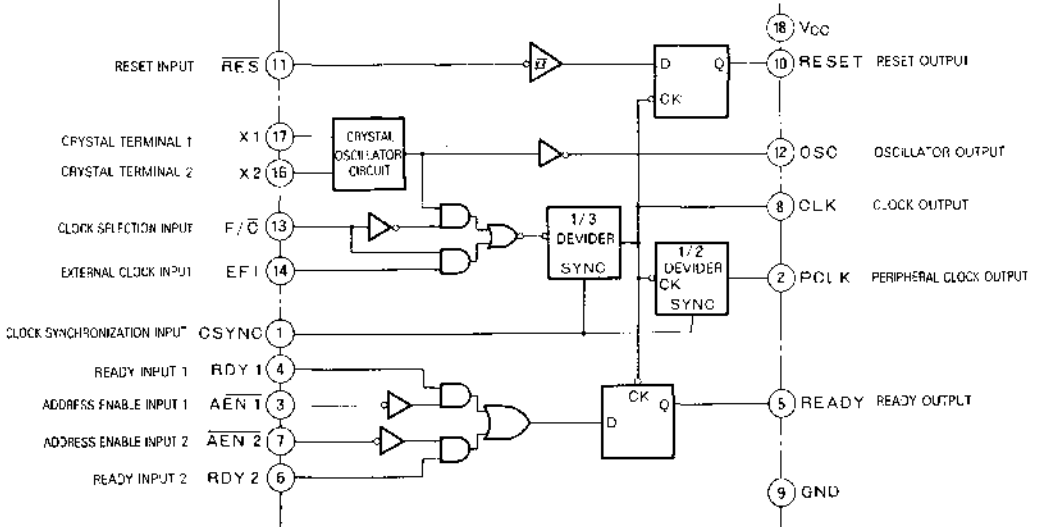

The clock synchronization input CSYNC is used to operate multiple M5L8284Ps in synchronous.

The ready inputs RDY1 and RDY2 are used to generate the ready output READY. These ready inputs are valid when the address enable inputs $\overline{AEN1}$ or $\overline{AEN2}$ respectively are low.

The PCLK, RESET, and READY signals operate internally synchronized to the CLK signal.

9

BLOCK DIAGRAM

CLOCK GENERATOR AND DRIVER FOR 8086, 8088, 8089 PROCESSORS

PIN DESCRIPTIONS

Pin	Name	Input or output	Function
$\overline{\text{AEN1}}$, $\overline{\text{AEN2}}$	Address enable input	Input	When $\overline{\text{AEN1}}$ and $\overline{\text{AEN2}}$ are made low, RDY1 and RDY2 are made effective respectively. By using these two inputs separately, the CPU can be used to access two Multibusses. When not used as a multimaster, $\overline{\text{AEN}}$ should be set to low. These inputs are active low.
RDY1, RDY2	Bus ready input	Input	These inputs are connected to the signal indicating the completion of data reception from a system bus device or a signal output indicating that data is valid. RDY1 and RDY2 are effective when $\overline{\text{AEN1}}$ and $\overline{\text{AEN2}}$ are low respectively. These inputs are active high.
READY	Ready output	Output	The state of RDY appears at this output in synchronization with the CLK output. This is done to synchronize the READY output to the M5L8284P internal CLK because the RDY input changes in an asynchronous fashion with respect to CLK. This pin is normally connected to the CPU ready input and cleared after the required CPU hold time, t_{H1} .
X ₁ , X ₂	Crystal element terminals	Input	These pins are used to make connections to the crystal. The crystal should have a frequency such that the period is three times the CPU cycle time. The crystal should be chosen in the range 12~25MHz and have as low as possible a series resistance. Care should be taken not to ground these pins.
F/C	Clock selection input	Input	When this input is set to low, the CLK and PCLK outputs are driven from the crystal oscillator output and when it is set to high, they are driven from the EFI input.
EFI	External clock input	Input	When F/C is high, the signal input at this pin is used to drive CLK and PCLK. The input is a rectangular TTL level signal of frequency such that the period is three times the CPU cycle time.
CLK	Clock output	Output	This output is connected to the CPU and the clock inputs of the surrounding ICs connected to the local bus. The output waveform is 1/3 the frequency of the crystal connected to X ₁ and X ₂ or the EFI input frequency and has a duty cycle of 1/3. Since for V _{CC} = 5V, V _{OH} ≥ 4.5V, this output can be directly connected to the CPU clock input.
PCLK	Peripheral clock output	Output	This output is used as the clock signal for peripheral devices. The output waveform is a 50% duty cycle TTL level rectangular waveform having a frequency of 1/2 the CLK output frequency.
OSC	Oscillator output	Output	This output is a TTL level crystal oscillator circuit output. The frequency is the same as that of the crystal connected to X ₁ and X ₂ but care should be taken as the frequency will be unstable if these pins are left open.
$\overline{\text{RES}}$	Reset input	Input	This active low input is used to generate the reset output signal for the CPU. The input uses a Schmitt trigger circuit so that by connecting a capacitor and resistance, the CPU power-up reset can be generated.
RESET	Reset output	Output	Connected to the CPU RESET input. The $\overline{\text{RES}}$ is synchronized to the CLK signal. This output is active high.
CSYNC	Clock synchronization input	Input	For using multiple M5L8284P devices, this input is used as a clock synchronization input. When CSYNC is made high, the internal counter of the M5L8284P is reset and when it is made low it begins operation. CSYNC must be synchronized with EFI. Refer to the Section on using this device.

M5L8284P

CLOCK GENERATOR AND DRIVER FOR 8086, 8088, 8089 PROCESSORS

LOAD CIRCUIT

TIMING DIAGRAM (Reference level = 1.5V)

APPLICATION NOTES

(1) Connecting the crystal

The crystal frequency should be chosen such that the period is three times the cycle time of the 8086 or 8088 and when connecting it care should be taken that it is located as close as possible to the M5L8284P.

To ensure stable oscillations, a ceramic capacitor should be placed in series with the crystal at pin X_2 . Suitable values of capacitance for 15MHz, 12MHz, and 22MHz, are 12~15pF, 24pF, and 8pF respectively.

(2) External clock connections

The maximum frequency of the external clock is 25MHz and while there is no lower limit on the frequency it should be set at least three times the CPU minimum clock frequency.

(3) Synchronizing using the CSYNC input

• When the EFI input is used

CLOCK GENERATOR AND DRIVER FOR 8086, 8088, 8089 PROCESSORS

• When the EFI input is not used

Since the 8086, 8088 and 8089 require a reset pulse over $50\mu s$ after V_{CC} reaches 4.5V upon power up, the capacitor value should be determined by the graph shown below. Note that the time for V_{CC} to reach 4.5V has not been considered so that it is necessary to use a value of C larger than in the power supply used.

$$V_C(t) = V \left(1 - e^{-\frac{t}{RC}} \right)$$

$$V = 4.5V$$

$$t = 50\mu s$$

$$V_C(t) = 1.05V$$

$$RC = 190 \times 10^{-6}$$

(4) Power-on reset circuit

PRECAUTIONS FOR USE

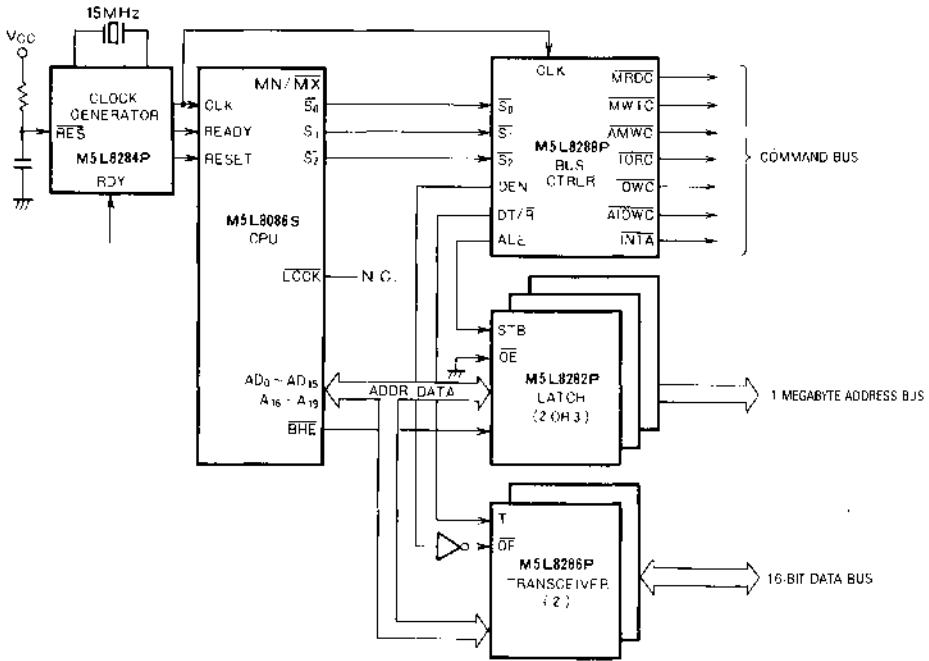

If noise is allowed to enter the XTAL1 and XTAL2 or V_{CC} pins, the oscillator frequency will be pulled off the parallel resonant frequency and the stray capacitance between XTAL1 and XTAL2 may cause the circuit to go into relaxation oscillation. To prevent this, care should be given to the following points.

- (1) The crystal should be one with a small parallel capacitance.
- (2) A capacitor of value 0.01 to $0.1\mu F$ with good high frequency characteristics should be connected between V_{CC} and the ground. This capacitor should be mounted as close as possible to the IC.

 BUS INCREASES

MITSUBISHI BIPOLAR DIGITAL ICs M5L8286P/M5L8287P

OCTAL BUS TRANSCEIVER

DESCRIPTION

The M5L8286P and M5L8287P are semiconductor integrated circuits consisting of a set of eight 3-state output bus transceivers for use with a variety of microprocessor systems.

FEATURES

- 3-state, high-fanout outputs ($I_{OL} = 16\text{mA}$, $I_{OH} = -1\text{mA}$ for the A outputs and $I_{OL} = 32\text{mA}$, $I_{OH} = -5\text{mA}$ for the B outputs)
- Electrical and pin compatibility with the Intel 8286 and 8287

APPLICATION

Two-way bus transceivers for microcomputer systems

FUNCTION

The M5L8286P and M5L8287P are two-way bus transceivers with non-inverted and inverted outputs respectively.

When the output enable input \overline{OE} is high, the local bus data pins $A_0 \sim A_7$ and system data pins $B_0 \sim B_7$ are both placed in the high-impedance state.

When the output enable input \overline{OE} is low, the input and output states are controlled by the transmit input T.

When T is high, $A_0 \sim A_7$ are input pins and $B_0 \sim B_7$ are output pins. When T is low, $B_0 \sim B_7$ are input pins and $A_0 \sim A_7$ are output pins.

APPLICATION EXAMPLE

M5L8288P

BUS CONTROLLER FOR 8086, 8088, 8089 PROCESSORS

DESCRIPTION

The M5L8288P is a semiconductor integrated circuit consisting of a bus controller and bus driver for the 8086 and 8088, 16-bit microprocessors. By using the status signals from the CPU a Multibus (Intel trademark) control signal is generated.

FEATURES

- High-fanout outputs
Command output $I_{OL}=32\text{mA}$, $I_{OH}=-5\text{mA}$
Control output $I_{OL}=16\text{mA}$, $I_{OH}=-1\text{mA}$
- Advanced command outputs (A $\overline{I}O\overline{W}C$ and $\overline{A}M\overline{W}C$ outputs)
- Pin and electrical compatibility with the Intel 8288

APPLICATION

Bus controller and bus driver for maximum mode operation of the 8086 and 8088

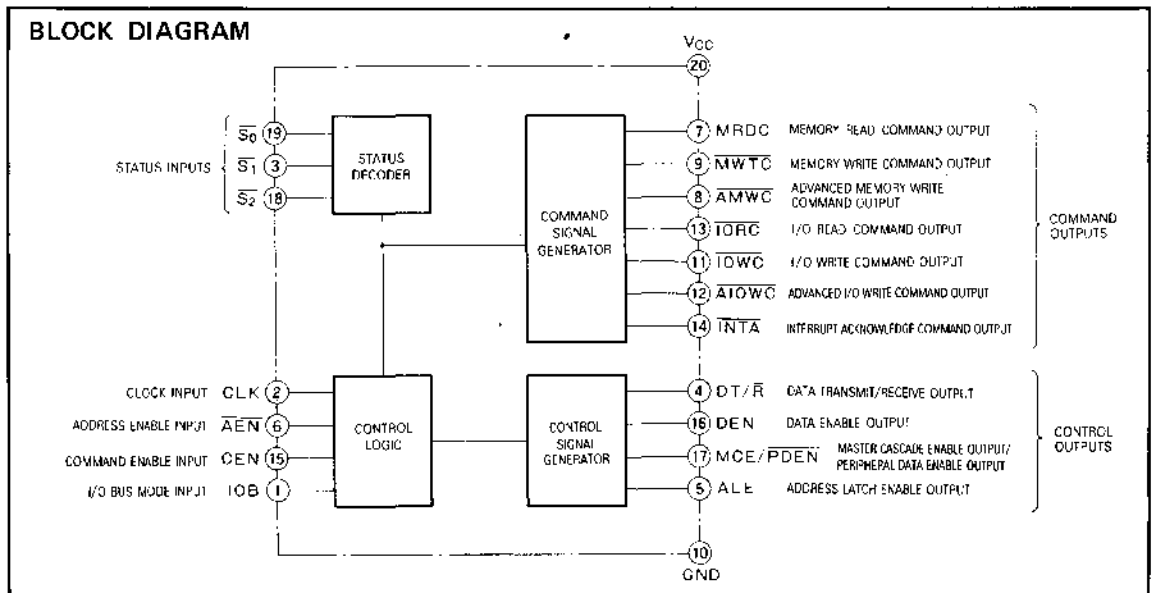

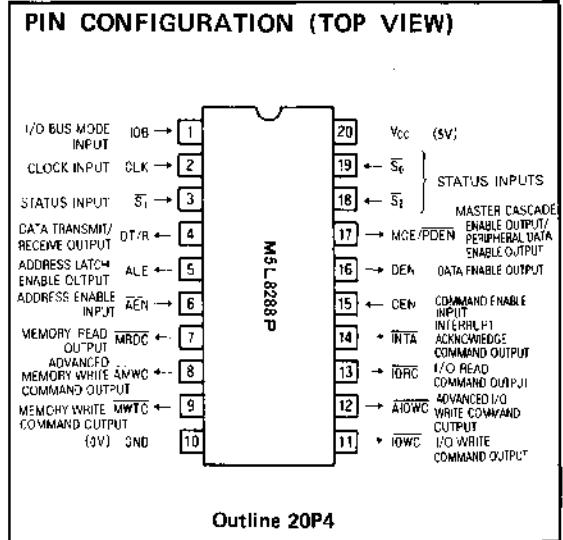

FUNCTION

The M5L8288P is a bus controller and driver for maximum mode operation of the 8086 and 8088 processors.

The command signals and control signals are decoded by means of the $\overline{S}_0 \sim \overline{S}_2$ outputs from the CPU and the control signals for I/O devices and memory are output.

The device can be used in the Multimaster mode in which several CPUs acting as masters are connected to one data bus. An input pin for the control signal \overline{AEN} from an 8289 bus arbiter is provided.

By using the M5L8288P as a bus controller, a high-performance 16-bit microcomputer system can be configured.

BUS CONTROLLER FOR 8086, 8088, 8089 PROCESSORS

PIN DESCRIPTIONS

Pin	Name	Input or output	Functions
$\overline{S_0}, \overline{S_1}, \overline{S_2}$	Status input	Input	These are connected to the CPU status output $\overline{S_0} \sim \overline{S_2}$. The M5L8288P uses these signals to generate the proper timing command signals and control signals. All pins are provided with internal pull-up resistors.
CLK	Clock input	Input	Used to connect the clock generator M5L8284P clock output CLK. All outputs of the M5L8288P change in synchronization with the clock input.
ALE	Address latch enable output	Output	Provides the strobe signal output for the address latches. This pin is connected to the STB pin of the M5L8282P or M5L8283P and used to latch the address from the CPU. When using any other address latch, the following conditions must be satisfied: 1. The enable input must be active high. 2. Data reading is always performed while the enable input is high. 3. The latching operation is performed as the enable input goes from high to low.
DEN	Data enable	Output	Provides the data enable signal for the local bus or a data transceiver on the system bus. Operates in active high mode.
DT \overline{R}	Data transmit/receive control output	Output	Controls the flow of data between CPU and memory or peripheral I/O devices. When this pin is high, the CPU can write data to the peripheral devices. When it is low, it can read data from the peripheral devices. It is connected to the transmit input T of the M5L8286P or M5L8287P bus transceivers.
\overline{AEN}	Address enable input	Input	When the \overline{IOB} input is low and the \overline{AEN} input is set to high, all command outputs are put in the high-impedance state. When the \overline{IOB} input is high, there is no effect on the \overline{IORC} , \overline{IOWC} , \overline{AMWC} , and \overline{INTA} outputs, the command output other than these four going into the high impedance state. None of the command outputs will go low until at least 115ns after \overline{AEN} transits from high to low.
\overline{CEN}	Command enable input	Input	When this pin is set to low, all command outputs and DEN are prohibited by the \overline{FDEN} control output (not high-impedance state). When set to high, the above outputs are enabled.
\overline{IOB}	Input/output bus mode input	Input	When this pin is set to high, the M5L8288P functions in the I/O bus mode, and when set to low it functions in the system bus mode. (The I/O bus mode and system bus mode are described in the functional description).
\overline{AOWC}	Advanced I/O write command output	Output	The \overline{AOWC} issues an I/O Write Command earlier in the machine cycle to give I/O devices an early indication of a write instruction. Its timing is the same as a read command signal. Active low.
\overline{IOWC}	I/O write command output	Output	Instructs an I/O device to read the data on the data bus. Active low.
\overline{IORC}	I/O read command output	Output	Instructs an I/O device to drive its data onto the data bus. Active low.
\overline{AMWC}	Advanced write command output	Output	The \overline{AMWC} issues a memory write command earlier in the machine cycle to give memory devices an early indication of a write instruction. Its timing is the same as a read command signal. Active low.
\overline{MWTC}	Memory write command output	Output	Provides a write instruction to memory for the current data on the bus. Active low.
\overline{MRDC}	Memory read command output	Output	Provides an output instruction to memory for the present data on the bus. Active low.
\overline{INTA}	Interrupt acknowledge command output	Output	This output informs an interrupting device that it has accepted the interrupt, outputting a vector address output instruction to the data bus. \overline{IORC} operates in the same manner for interrupt cycles. Active low.

BUS CONTROLLER FOR 8086, 8088, 8089 PROCESSORS

Pin	Name	Input or output	Functions
MCE / PDEN	Master cascade Enable output/ Peripheral data Enable output	Output	This output pin has two functions. 1. When the IOB input is set to low The MCE function is enabled. The signal acts as the enable signal which allows a slave PIC (M5L8259API) to read the cascade address output to the bus by the master PIC during an interrupt sequence. Active high. 2. When the IOB input is set to high. The PDEN function is enabled. This output provides the enable signal to the data bus transceiver connected to the I/O interface bus when an instruction occurs (IORC, IOWC, AIOWC, INTA). Operates the same way as DEN with respect to the system bus.

FUNCTIONAL DESCRIPTION

The state of the command outputs and control outputs are determined by the CPU status outputs $\overline{S_0} \sim \overline{S_2}$. The table

summarizes the states of the outputs $\overline{S_0} \sim \overline{S_2}$ and their corresponding valid command output names.

STATUS INPUTS AND COMMAND OUTPUTS RELATIONSHIPS

$\overline{S_2}$	$\overline{S_1}$	$\overline{S_0}$	8086, 8088 status	Valid command output name
L	L	L	Interrupt acknowledge	INTA
L	L	H	Data read from an I/O port	IORC
L	H	L	Data write to an I/O port	IOWC, AIOWC
L	H	H	Halt	—
H	L	L	Instruction fetch	MRDC
H	L	H	Read data from memory	VRDC
H	H	L	Write data to memory	MWTC, AMWC
H	H	H	Passive state	—

Depending upon whether the M5L8288P is in the I/O bus mode or system bus mode, the command output sequence will vary.

1. I/O bus mode operation

When IOB is high, the M5L8288P function in the I/O bus mode.

In the I/O Bus mode all I/O command lines (IORC, IOWC, AIOWC, INTA) are always enabled (i.e., not dependent on AEN). When an I/O command is initiated by the processor, the 8288 immediately activates the command lines using PDEN and DT/R to control the I/O bus transceiver. The I/O command lines should not be used to control the system bus in this configuration because no arbitration is present. This mode allows one 8288 Bus Controller to handle two external busses. No waiting is involved when the CPU wants to gain access to the I/O bus. Normal memory access requires a "Bus Ready" signal (AEN LOW) before it will proceed. It is advantageous to use the IOB mode if I/O or peripherals dedicated to one processor exist in a multi-processor system.

2. System bus mode operation

When IOB is set to low, the M5L8288P enters the system bus mode. In this mode no command is issued until 115 ns after the AEN Line is activated (LOW). This mode assumes bus arbitration logic will inform the bus controller (on the AEN line) when the bus is free for use. Both memory and I/O commands wait for bus arbitration. This mode is used when only one bus exists. Here, both I/O and memory are shared by more than one processor.

3. AMWC and AIOWC outputs

With respect to the normal write control signals MWTC and IOWC, the advanced-write command signals AMWC and AIOWC transit low one clock cycle earlier and remain low for two clock cycles.

These signals are used with peripheral devices or static RAM devices which require a long write pulse, so that the CPU does not go into an unnecessarily wait cycle.

BUS CONTROLLER FOR 8086, 8088, 8089 PROCESSORS

ABSOLUTE MAXIMUM RATINGS ($T_a=0\sim 75^\circ\text{C}$, unless otherwise noted)

Symbol	Parameter	Conditions	Limits	Unit

APPLICATION EXAMPLE

SPEECH SYNTHESIS LSI_s (PARCOR SYSTEM)

MITSUBISHI LSIs M58817AP

SPEECH SYNTHESIZER

DESCRIPTION

The M58817AP is a p-channel MOS speech synthesizer making use of the LPC (PARCOR) method.

By using the device with one type M58818-XXXX device, approximately 100 seconds (maximum) of speech output can be achieved.

The M58819S EPROM is also available for use with the M58817AP.

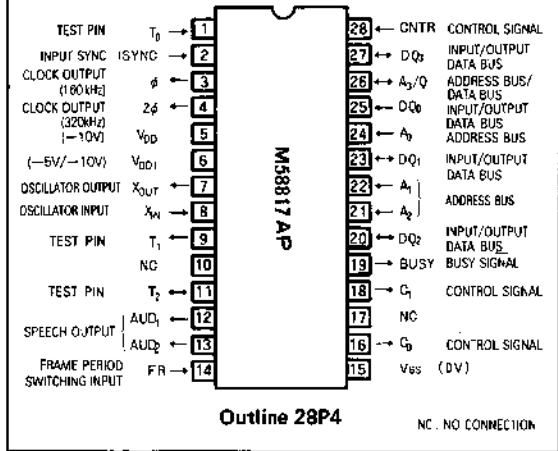

FEATURES

- Single -10V power supply
- May be used with 5V microcomputers by use of a dual -5V/-10V supply
- Selectable characteristic parameter compression density
Low audio quality: 1.96K-bit/s (max)
High audio quality: 3.92K-bit/s (max)
- Male and female voices or sound effects mixed
- Usable with up to 16 phrase ROMs
- Direct speaker drive is possible
- By use of just one masked ROM up to 100 seconds of speech output is possible

APPLICATIONS

Clocks, educational equipment, toys, electronic cash registers.

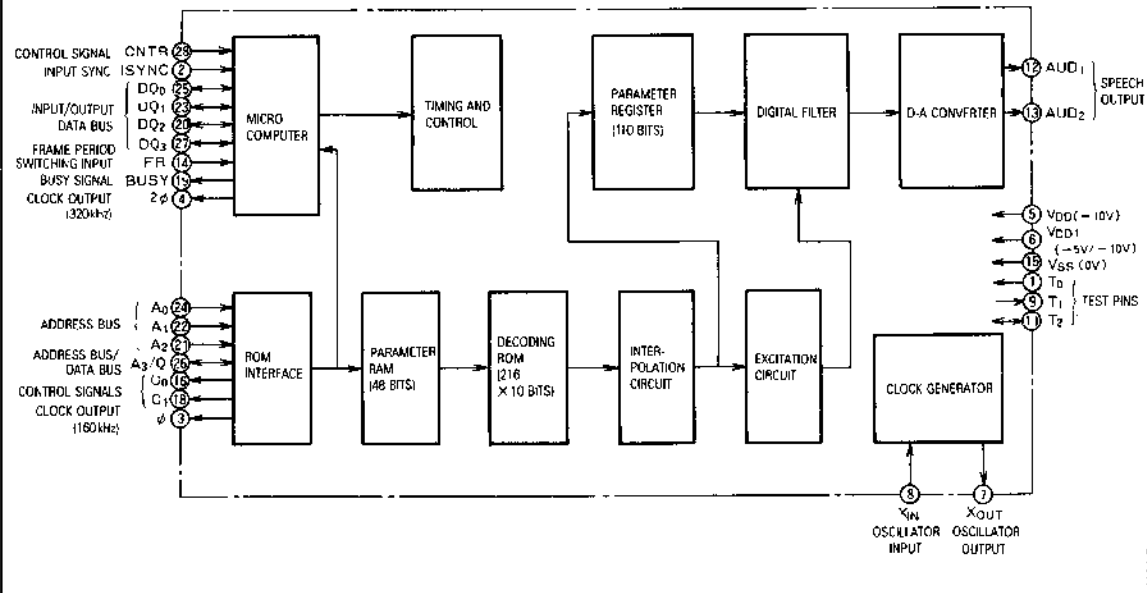

PIN CONFIGURATION (TOP VIEW)

FUNCTION

The M58817AP is an LPC (PARCOR) speech synthesizer consisting of a microcomputer interface, parameter storage RAM, decoding ROM, interpolation logic, parameter register, excitation circuit, ROM interface, lattice-type digital filter (pipeline multiplier, adder, stack and registers, etc.), D-A converter, timing logic circuitry, and clock oscillator.

BLOCK DIAGRAM

10

SPEECH SYNTHESIZER

BASIC FUNCTION BLOCKS

Function	Operational description
Microcomputer interface	Signal exchange with an external controller
Timing logic	Internal timing control
ROM interface	Data exchange with ROM
Parameter storage RAM (48 bits)	Temporary storage of one frame of voice parameters (K-parameter, pitch and amplitude)
Decoding ROM (216 x 10 bits)	Decoding of non-linearly coded parameters stored in RAM
Interpolation logic	Linear interpolation of K parameters, pitch and amplitude every 3.125ms
Excitation circuit	Consists of a white noise and pulse generator used to generate voiced and unvoiced sounds
Parameter register (110 bits)	A register used to temporarily store linearly interpolated data
Digital lattice filter	A 14-bit 10-stage lattice filter used to control the spectral shape, producing linearly approximated data.
D-A converter	8-bit (including sign) D-A converter
Clock generator	Generates a clock by means of an externally connected ceramic element

FUNCTIONAL DESCRIPTION

The M58817AP can be controlled by an external system by means of eight instructions.

- Addressing instruction:** Used to set phrase ROM addresses
- Indirect addressing instruction:** Used to indirectly set phrase ROM addresses
- Bit read instruction:** Used to shift into a 4-bit shift buffer 1-bit of contents from the phrase ROM
- Data transmission instruction:** Outputs the contents of the 4-bit shift buffer
- Test instruction:** Test whether speech generation has been completed
- Male speaker instruction:** Start instruction for voice generation (male)
- Female speaker instruction:** Start instruction for voice generation (female)
- Stop instruction:** Stop the speech generating

Operation begins with the setting of the phrase ROM address counter to the address specified by an addressing instruction or indirect addressing instruction.

Next, upon generation of a male speech or female speech instruction from the controller, the synthesizer enters the speech start-mode and accesses the phrase ROM every 25ms to receive one frame of voice characteristic parameters. In response to demands from the synthesizer, parameters are sent to the synthesizer in bit-serial form. For this transmis-

PIN DISCIPTION

Pin	Name	Input or output	Function
ISYNC	Input sync	Input	Use as a sync signal for commands and data from an external controller
ϕ	Clock output	Output	160kHz clock output
2 ϕ	Clock output	Output	320kHz clock output
X IN	Oscillator input	Input	Used to set the frequency of the internal clock generator by means of an external RC circuit or IF-type ceramic filter connected between X-out and this pin.
X OUT	Oscillator output	Output	Output of the internal clock generator (540kHz)
T ₀ ~T ₂	Test pin	Input/output	Test pin
AUD ₁ AUD ₂	Speech output	Output	Speech output
FR	Frame period switching signal	Input	Used to set the frame length, 25ms when open and 12.5ms when grounded
C ₀ C ₁	Control signals	Output	Control of external ROM
BUSY	Busy signal	Output	Used to verify the presence of voice output, high during voice output
DQ ₀ ~ DQ ₃	Input data bus	Input/output	Two-way bus used to manage commands and data from an external controller
A ₀ ~ A ₂	Address bus	Output	Used for external memory addresses
A ₃ /Q	Address bus/data bus	Input/output	Used to accept addresses and data from external memory
GNTR	Control signal	Input	Used for external control. When high, the external controller effects a command using the sync signal and the signals DQ ₀ through DQ ₃ .

sion, the phrase ROM address counter is automatically incremented with the 8-bit ROM words converted to serial format.

The transmitted parameters are then expanded and interpolated by the synthesizer, whereupon PARCOR voice generation is performed with a cycle time of 125 μ s (8kHz rate), and D-A conversion to analog speech is performed to generate the output speech signal.

At the last frame of speech parameters stored in the phrase ROM, an end-code is written to signify the end of the parameter stream. When this code is detected, speech generation is halted.

To indicate whether speech generation is in progress, a test instruction may be generated or the synthesizer busy signal may be used (high for speech generation).

When a bit read instruction is generated, the 1-bit contents of the address specified by the phrase ROM address counter is sent to the synthesizer's 4-bit shift

SPEECH SYNTHESIZER

buffer, shifting in serial fashion. The address counter is automatically incremented.

The data transmission instruction causes the synthesizer's 4-bit shift buffer contents to be transmitted in parallel. Thus, by using the bit read and data transmission instructions any arbitrary address contents from the phrase ROM may be read.

The STOP instruction can be used to halt speech generation.

TABLE 1. INSTRUCTION CODES

Instruction	Data bus line DQ				Transmission direction		IDB
	DQ ₃	DQ ₂	DQ ₁	DQ ₀	Controller C	Synthesizer S	
Stop	0	0	0	—			CIR ₀
Address setting	0	0	1	—			CIR ₁
Data transmission	0	1	0	—			CIR ₂
Female speaker	0	1	1	—			CIR ₃
Bit read	1	0	0	—	C	← S	CIR ₄
Male speaker	1	0	1	—			CIR ₅
Indirect address	1	1	0	—			CIR ₆
Test	1	1	1	—			CIR ₇

Note: 1 & 0 refer to high- and low-level signals
 "—" indicates a non-defined level I_{DD}
 refers to the data bus lines

Addressing is performed by sending address setting instructions to the data bus line DQ, and as shown in Table 2, is achieved in the order from lower bits to higher bits in groups of 4 bits. After the address has been set, for direct addressing the bit read instruction is used while for indirect addressing an indirect address instruction is sent to the data bus line.

TABLE 2. ADDRESS SETTING

Data bus line DQ				Transmission direction		IDB
DQ ₃	DQ ₂	DQ ₁	DQ ₀	Controller C	Synthesizer S	
a ₃	a ₂	a ₁	a ₀			CAD ₀
a ₇	a ₆	a ₅	a ₄			CAD ₁
a ₁₁	a ₁₀	a ₉	a ₈	C	← S	CAD ₂
a ₁₅	a ₁₄	a ₁₃	a ₁₂			CAD ₃
—	—	a ₁₇	a ₁₆			CAD ₄

Note that a₀ and a₁₇ refer to the least significant and most significant bits respectively

When data transmission instructions are sent, the data from the synthesizer's 4-bit shift buffer is sent to the external controller.

TABLE 3. DATA TRANSMISSION

Data bus line DQ				Transmission direction		IDB
DQ ₃	DQ ₂	DQ ₁	DQ ₀	Controller C	Synthesizer S	
S ₃	S ₂	S ₁	S ₀	C ←	— S	SRD

S₀: Least significant bit
 S₃: Most significant bit

When a test instruction is generated, a signal is output via the external controller data bus line DQ₀.

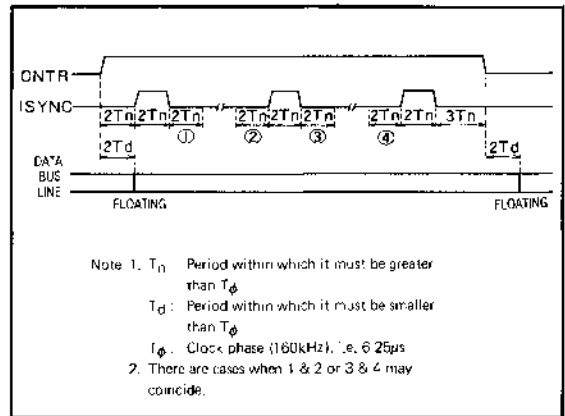

TABLE 4. TEST INSTRUCTION

Data bus line DQ				Transmission direction		IDB
DQ ₃	DQ ₂	DQ ₁	DQ ₀	Controller C	Synthesizer S	
—	—	—	(SM)	C ←	— S	STK

SM = 0: Non-speech generating mode
 1: Speech generation
 —: Non-defined state

INSTRUCTION EXECUTION TIME

It is necessary to satisfy the timing conditions for all eight instructions as shown in Fig. 1.

10

When the CNTR signal is set to high, using the ISYNC signal and the data bus line, synthesizer instructions may be specified to control data transmission and reception. When the CNTR signal is made low, the synthesizer cannot be controlled by the controller, the data bus line being floated.

Fig. 2~9 show the bus line timing relationships and execution times for the eight types of instructions.

In the diagrams codes surrounded by a rectangle represent instructions and the times in which they are generated.

INSTRUCTION SET
DEFINITION OF SYMBOLS

- DQ: Interface data bus line
- DQ_i (i = 0~3): i-th bit of DQ
- a: 18-bit data used for addressing
- a_k (k = 0~17): k-th bit of a
- A: 18-bit phrase ROM address
- A_k (k = 0~17): k-th bit of A
- S: 4-bit shift buffer
- S_i (i = 0~3): i-th bit of S
- R {A}: Contents of ROM at the address specified at A
- R_j (A): (j = 0~7): Value of the i-th bit of R (A)

USING THE INSTRUCTION SET
1. Direct and Indirect Addressing Instruction
(1) Direct addressing

Instruction code:

DQ ₃	DQ ₂	DQ ₁	DQ ₀
0	0	1	—
a ₃	a ₂	a ₁	a ₀
0	0	1	—
a ₇	a ₆	a ₅	a ₄
0	0	1	—
a ₁₁	a ₁₀	a ₉	a ₈
0	0	1	—
a ₁₅	a ₁₄	a ₁₃	a ₁₂
—	—	a ₁₇	a ₁₆
1	0	0	—

10

As shown above data is input to the synthesizer from top to bottom in sequence from the external controller.

SPEECH SYNTHESIZER

Function equations: $(A) \leftarrow a$

Instruction Description

This instruction directly sets the phrase ROM address.

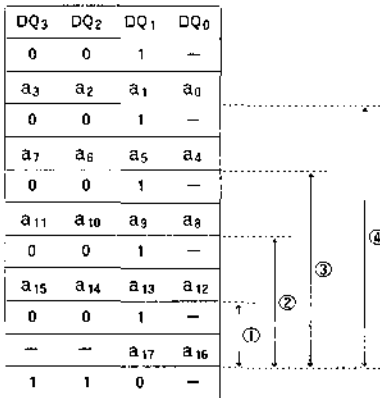

By using this instruction, the 1st bit, i.e. $R_0(A) = R_0(a)$ of the 8-bit contents of the phrase ROM at the specified address is specified. Note that the upper order bits $a_{14} \sim a_{17}$ are specified by the phrase ROM chip select data.

When the contents of the address counter previous to this instruction are known and it is not necessary to change the upper order bits $a_{14} \sim a_{17}$, the appropriate setting step from 1 to 4 may be eliminated.

After outputting of data a_{16} and a_{17} , this instruction requires a minimum time of $24T_{\phi}$ during which bit read instructions must be output as dummies. T_{ϕ} is the clock period.

1. Indirect Address

Instruction Code:

As shown above data is input to the synthesizer starting from the top sequentially.

Function equations:

- First, $(A) \leftarrow a$, where $(A_E) = a$
- Next, $(A_j) \leftarrow R_j(a) \equiv R_j((A_E))$ where $j = 0 \sim 7$
- $(A_{8+j}) \leftarrow R_j(a+1) \equiv R_j((A_E)+1)$ where $j = 0 \sim 5$
- $(A_j) = a_j$ where $j = 14 \sim 17$

Note that the above excludes the case for which $a_0 \sim a_{13}$ of (A_E) are all ones.

Instruction Description

This instruction indirectly specifies the phrase ROM address.

By using this instruction, the first bit, i.e. $R_0(A) = R_0(a)$, of the 8-bit phrase ROM contents at the specified address is specified.

First, this instruction sets the address counter A to the address data a. This address is used as (A_E) . Next, the ROM

output $R_0(A_E) \sim R_7(A_E)$ at the specified address (A_E) is sent to the address counter $A_0 \sim A_7$, and the ROM output $R_0(A_E+1) \sim R_5(A_E+1)$ at the next address from $a(A_E)$, $(A_E)+1$ is sent to the address counter $A_8 \sim A_{13}$. The upper order 4-bits $A_{14} \sim A_{17}$ of (A_E) do not change, however. The value of the set address data a must not be the individual phrase ROM last address.

If the contents of the address counter prior to this instruction are known and there is no necessity to change higher order address bits, the appropriate step 1 through 4 may be eliminated.

After outputting the data a_{16} and a_{17} , this instruction requires a minimum of $74T_{\phi}$.

2. Bit Read Instruction

Instruction code:

DQ3	DQ2	DQ1	DQ0
1	0	0	—

Function equations:

- First $(S_0) \leftarrow (S_1)$
- $(S_1) \leftarrow (S_2)$
- $(S_2) \leftarrow (S_3)$
- $(S_3) \leftarrow R_j(A)$ where $j = 0 \sim 7$ and $j = 0$ immediately after the instruction.
- Next, $j \leftarrow j + 1$ where $j \leftarrow 0$ if $j = 8$
- $(A) \leftarrow (A) + 1$

Instruction Description

This instruction shifts into the 4-bit shift buffer S the contents of the phrase ROM. In addition, it acts to initialize the ROM after direct addressing.

By using this instruction, the 1st bit of the 8-bit contents of ROM specified by the address counter A is sent to the 4-bit shift buffer S. Immediately after execution, $R_0(A)$ is sent, and when this instruction is executed continuously, the address counter is automatically incremented in the sequence $R_0(A)$, $R_1(A)$... $R_7(A)$, $R_0(A+1)$, thereby performing a serial conversion on the ROM data automatically. In addition, the address counter A is incremented by bits allowing all 16 chips to be addressed.

SPEECH SYNTHESIZER

3. Data Transmission Instruction

Instruction code:

DQ ₃	DQ ₂	DQ ₁	DQ ₀
0	1	0	-

Function equations:

$$(DQ_0) \leftarrow (S_0)$$

$$(DQ_1) \leftarrow (S_1)$$

$$(DQ_2) \leftarrow (S_2)$$

$$(DQ_3) \leftarrow (S_3)$$

Instruction Description

This instruction outputs to the interface data bus line DQ the 4-bit contents of the shift buffer S.

By using this instruction, the 4-bit data contents of the phrase ROM can be read externally.

4. Test Instruction

Instruction code:

DQ ₃	DQ ₂	DQ ₁	DQ ₀
1	1	1	-

Function equations: $(DQ_0) \leftarrow (SM)$

SM=1 for speech generation and 0 for non-generation speech, with DQ₁~DQ₃ non-defined.

Instruction Description

This instruction is used to test whether speech generation is being performed and output the result at DQ₀.

Use of this instruction allows the speech mode (SM) status to be output as a DC level at the busy pin as well. SM and BUSY are of the same polarity, 1 for periods of speech generation and 0 for non-generation periods.

5. Speech Instruction

Instruction code:

DQ ₃	DQ ₂	DQ ₁	DQ ₀
1	0	1	-
0	1	1	-

Male speaker
 Female speaker

Function equations:

- (1) Speech synthesizer $\leftarrow R_j ((A))$
 $j = 0 \sim 7$ and $j = 0$ directly after an addressing instruction
- (2) $j \leftarrow j + 1$, however $j \leftarrow 0$ if $j = 8$
 $(A) \leftarrow (A) + 1$
 (1) and (2) are repeated.

Instruction Description

These instructions are used to begin and execute speech generation by the speech generating equipment.

Using these instructions, speech characteristic parameters stored in the phrase ROM are sent to the synthesizer continuously at a rate of one frame every 25ms, the synthesizer processing them with a cycle time of 125 μ s. The results of this process are D/A converted every 125 μ s to create the AUD1 and AUD2 speech outputs. At each of AUD1 and AUD2 pins, an analog speech signal is output corresponding to the appropriate sign codes, one being positive and the other negative.

Use of these instructions automatically increments the 18-bit phrase ROM address counter A, and performs a serialization of ROM data.

As the last voice parameter frame in the phrase ROM, an end code is used so that the synthesizer, sending this end code is reset, ending the speech synthesis process cycle and setting the speech mode SM to 0.

Thus, with the exception of phrase ROM memory capacity, speech of any arbitrary length may be generated.

10

6. Stop Instruction
Instruction code:

DQ ₃	DQ ₂	DQ ₁	DQ ₀
0	0	0	—

INSTRUCTION FUNCTION

This instruction stops the speech output of the synthesizer.

Instruction Description

This instruction stops the speech generated by the synthesizer.

By using this instruction, speech generation is halted, and the speech mode SM is reset to 0.

The phrase ROM program counter is not modified.

Upon power up, it is always required to generate a stop instruction.

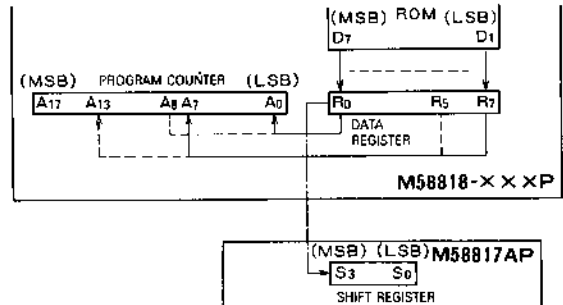

Example

This example generates female speech by sending the ROM program counter to the first address 0013F₁₆.

DQ ₃	DQ ₂	DQ ₁	DQ ₀	
0	0	1	0	Addressing instruction
1	1	1	1	F
0	0	1	0	Addressing instruction
0	0	1	1	3
0	0	1	0	Addressing instruction
0	0	0	1	1
0	0	1	0	Addressing instruction
0	0	0	0	0
0	0	1	0	Addressing instruction
0	0	0	0	0
1	0	0	0	Bit read instruction
0	1	1	0	Female speaker instruction

Data is transferred to the synthesizer (M58817AP) from the controller as shown above. Refer to the Timing Diagram for input timing.

Data Transfer Using the Bit Read Instruction and Indirect Addressing Instruction

Note ——— Bit read instruction
 ——— Indirect addressing instruction

(1) Using the bit read instruction

If a bit read instruction is output by the synthesizer, the upper order bit of the address specified by the program counter is transferred to the upper order bit (DQ₃) of the synthesizer register. By repetitively sending this instruction, the previously sent bits are shifted towards the lower order bits in the register. Thus, to observe data stored in ROM using the bit read instruction, the data must be stored after doing bit conversion in groups of 4 bits.

(2) Using the indirect addressing instruction

As can be seen in the Figure, the upper order and lower order bits for the contents of ROM and those of the program counter are reversed, requiring care when performing ROM storage operations.

SPEECH SYNTHESIZER

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit
VDD	Supply voltage	With respect to VSS	0.3 ~ -15	V
VI	Input voltage		0.3 ~ -15	V

APPLICATION EXAMPLES

(1) Use with M58818-XXXX

(2) Use with an EPROM

MITSUBISHI LSIs
M58818-XXXP

128K-BIT PHRASE ROM

DESCRIPTION

The M58818-XXXP is a p-channel MOS phrase ROM having a capacity of 16K bytes (131072 bits), intended for use in storage of speech parameters and other data. The device includes also an 18-bit address counter/register, an 8-bit output sense amplifier/buffer, address control circuitry, and read control circuitry.

Used in conjunction with the M58817AP speech synthesizer, up to 100 seconds of speech output can be obtained.

FEATURES

- Single -10V power supply
- Stores parameters for up to 100 seconds of speech output
- Large memory capacity (128K bits)
- Built-in 18-bit address counter/register

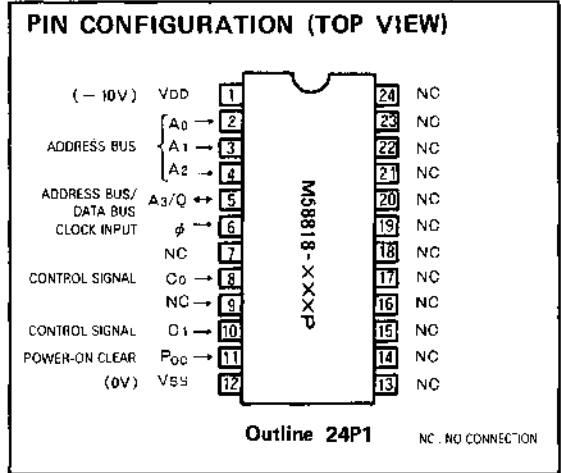

APPLICATIONS

Clocks, educational equipment, toys, electronic cash registers.

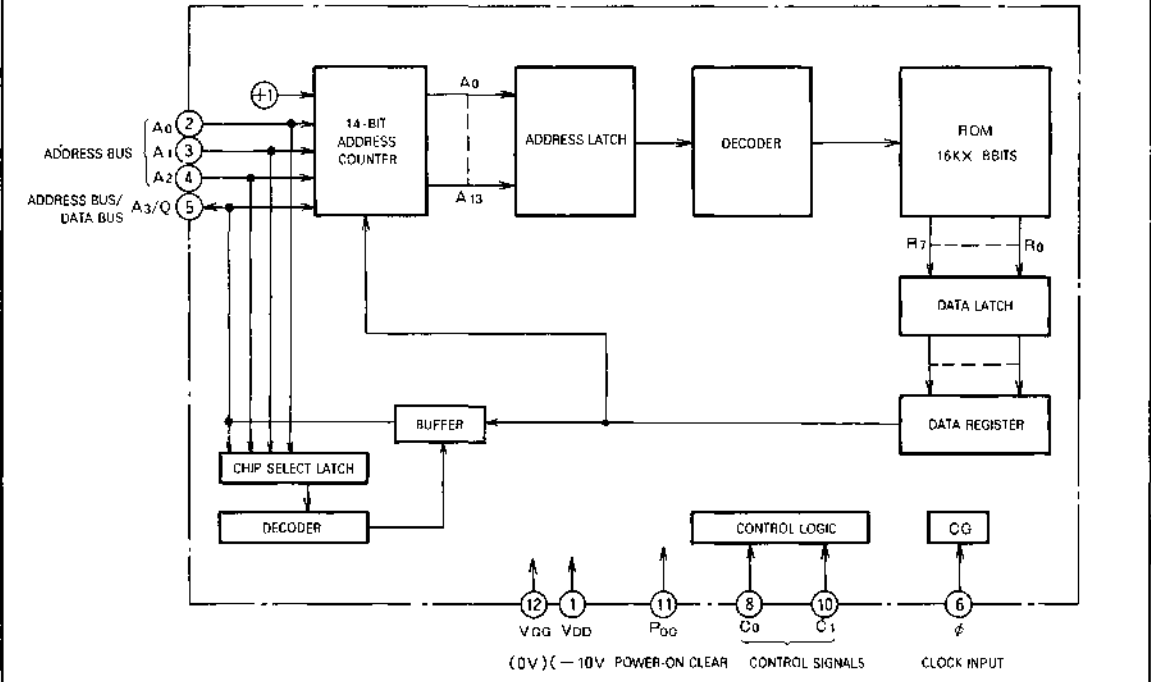

FUNCTION

The M58818-XXXP is a 16K x 8-bit masked ROM consisting of a 14-bit address counter, address latch, chip select latch, data register, and control logic circuitry.

Addressing is done by means of pins A₀ through A₃ in five steps.

BLOCK DIAGRAM

10

128K-BIT PHRASE ROM

BASIC FUNCTIONAL BLOCKS

Function	Operational description
Address counter	For continuous addressing of ROM data for output, this 14-bit pure binary address counter is automatically incremented by 1
Data register	This 8 bit register is used for temporary storage of ROM data
Control logic	Provides internal control by means of the control signals C ₀ and C ₁
Data memory	16K x 8 bit masked ROM

PIN DESCRIPTION

Pin	Name	Input or output	Function
A ₀ —A ₂	Address bus	Input	Input pins for the external input of address into the address counter and chip select latch. This data must be input in five steps
A ₃ /Q	Address bus/data bus	Input/output	In the address and chip select data input mode this pin acts as an input pin to accept address and data. This data must be input in five steps. In the data output mode this pin acts as an output pin, outputting ROM data 1 bit at a time in serial fashion. However, for address overflow and when the chip is not selected, this output pin is floating.
φ	Clock input	Input	Clock input pin
C ₀ C ₁	Control signals	Input	Determine internal operation status. Input pins for control signals.
P _{0c}	Power-on clear	Input	Upon power-on, an internal power-on clear circuit automatically clears the internal status. When this pin is set to high, A ₃ /Q output is prohibited and the internal states are cleared

FUNCTIONAL DESCRIPTION

The M58818-XXXP is controlled by the following four instructions.

Instruction	Effect	Instruction code	
		C ₀	C ₁
Address instruction	Data is loaded into the internal address counter and chip select latch of the M58818-XXXP	0	1
Read instruction	Serially converted data from the ROM is output 1 bit at a time. This may also be used as an addressing instruction capable of directly addressing ROM.	1	0
Indirect addressing instruction	Indirectly sets the address of ROM	1	1
NOP instruction	No operation	0	0

These instructions are described below.

1. Direct addressing

The timing is shown in Fig. 1. First, by using the addressing instruction, A₀, A₁, A₂, and A₃/Q inputs are used to read-in in 4-bit parallel format the starting address and chip select data. Then, five addressing instructions are used to completely set the contents of the address counter and chip select latch.

Next, if a read instruction is input, ROM data is read from the address specified by the sequence above.

The read instruction acts as a direct addressing instruction, and 24 clock cycles after the input of the read instruction ROM data is available at the A₃/Q pin. In addition, by inputting a read instruction ROM data can be serially output 1 bit at a time.

The address counter is automatically incremented by 1 every 8 read instructions.

Fig. 1 Direct addressing timing

10

2. Indirect addressing

The timing is shown in Fig. 2. As with direct addressing, an indirect addressing instruction is input after setting of the address.

By using an indirect addressing instruction, ROM data at the address in the address counter is output and shifted into the address counter.

In addition, when two words of ROM data are shifted into the address counter, 74 clock cycles after the input of an indirect addressing instruction the ROM data at the set address is available as an output at the A₃/Q pin.

By inputting a read instruction, ROM data can be read 1

bit at a time in serial fashion.

The relationship between the two words of ROM data and the address shifted into the address counter is as follows.

If the address counter address is set to (00000₁₆) when an indirect addressing instruction is input, the ROM data at that address (D₀ D₁ D₂ D₃ D₄ D₅ D₆ D₇)₂ and the ROM data at the address incremented 1 (00001₁₆) (D'₀ D'₁ D'₂ D'₃ D'₄ D'₅ D'₆ D'₇)₂ are output and shifted into the address counter, the overall address being set to (D'₅ D'₄ D'₃ D'₂ D'₁ D'₀ D₇ D₆ D₅ D₄ D₃ D₂ D₁ D₀)₂.

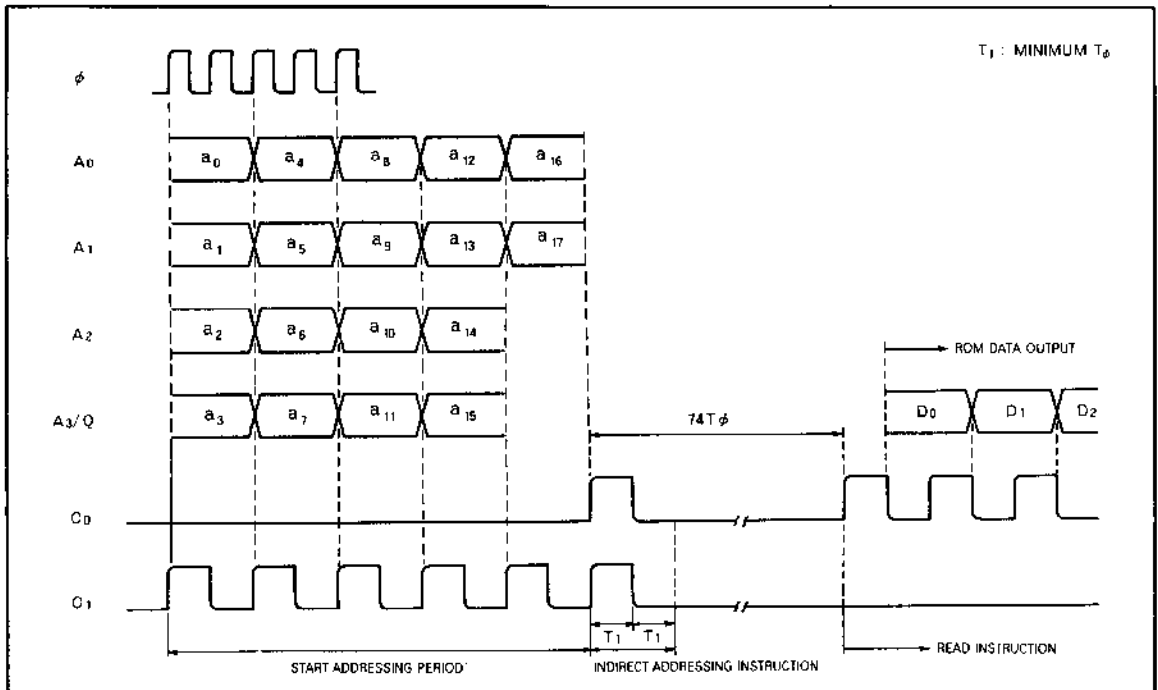

Fig. 2 Indirect addressing timing

3. Relationship of phrase ROM contents and address setting

Up to a maximum of 16 M58818-XXXP phrase ROMs may be connected to a single M58817AP synthesizer. Therefore, since the capacity of a single M58818-XXXP is 16K bytes (131072 bits), it is necessary to be able to address 256K bytes. That is, an 18-bit address a_i (i=0~17) is required the relationship between a_i and the ROM chip being as follows.

TIMING DIAGRAM

EPROM INTERFACE

DESCRIPTION

The M58819S is a p-channel MOS EPROM interface LSI device capable of addressing 16K bytes of EPROM devices.

The device is housed in a 40-pin ceramic DIL package.

Speech output is possible by using the M58819S in conjunction with the M58817AP and EPROMs.

FEATURES

- Single -10V power supply
- Extendable to control up to 16K bytes of EPROM
- Built-in 14-bit address counter

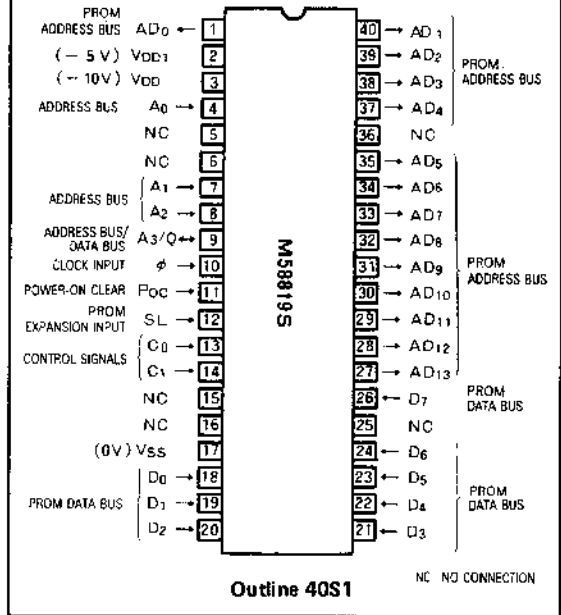

APPLICATION

Small-scale speech output devices.

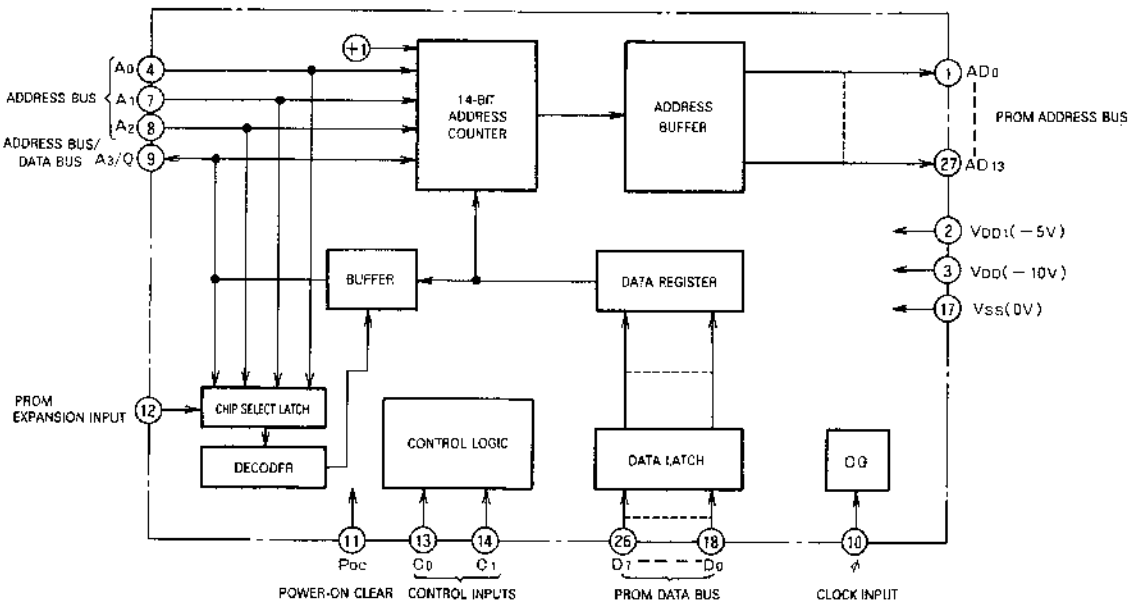

FUNCTION

The M58819S is an interface LSI which includes a 14-bit address counter, chip select latch, control logic circuitry, and a data register. It is usable in conjunction with EPROMs and the M58817AP speech synthesizer.

PIN CONFIGURATION (TOP VIEW)

BLOCK DIAGRAM

EPROM INTERFACE

BASIC FUNCTIONAL BLOCKS

Function	Operational description
Address counter	This counter is used to specify the address for external EPROMs. When this 14-bit binary counter is used to output continuous addresses for data output, it is automatically incremented by one.
Data register	This 8-bit register is used for temporary storage of EPROM data.
Control logic	Provides internal control by means of the control signals C_0 and C_1 .

PIN DESCRIPTION

Pin	Name	Input or output	Function
$AD_0 - AD_{13}$	PROM address bus	Output	Output pin which sends the 14-bit address to the EPROM devices.
$A_0 - A_2$	Address bus	Input	Input pins for the external input of address into the address counter and data into the chip select latch. This data must be input in five steps.
A_3/Q	Address bus/ data bus	Input/ output	In the address and chip select data input mode this pin acts as an input pin to accept address and data. This data must be input in five steps. In the data output mode this pin acts as an output pin, outputting EPROM data 1 bit at a time in serial fashion. However, for address overflow and when the chip is not selected, this output pin is floating.
ϕ	Clock input	Input	Clock input pin.
C_0 C_1	Control signals	Input	Input pins for the control signals which determine the internal operating states.
P_{OC}	Power on clear	Input	Upon power-on, an internal power-on clear circuit automatically clears the internal status. When this pin is set to high, A_3/Q output is prohibited and the internal states are cleared.
$D_0 - D_7$	PROM data bus	Input	8-bit parallel input for EPROM data.
SL	PROM expansion input	Input	Normally the SL pin is set to low, enabling addressing of 16K bytes of EPROM. For addressing of 32K bytes of EPROM with two M58819S devices, one of the SL pins is set to high. The chip select data is used to switch between the two devices.

EPROM INTERFACE

FUNCTIONAL DESCRIPTION

The M58819S is controlled by the following four instructions.

Instruction	Effect	Instruction code	
		C ₀	C ₁
Addressing instruction	Data is loaded into the internal address counter and chip select latch of the M58819S	0	1
Read instruction	Serially converted data from the EPROM is output 1 bit at a time. This may also be used as an addressing instruction capable of directly addressing EPROM	1	0
Indirect addressing instruction	Indirectly sets the address of EPROM	1	1
NOP instruction	No operation	0	0

These instructions are described below.

1. Direct addressing

The timing is shown in Fig. 1. First, by using the addressing instruction, A₀, A₁, and A₃/Q inputs are used to read-in in 4-bit parallel format the starting address and chip select data. Then, five addressing instructions are used to completely set the contents of the address counter and chip select latch.

Next, if a read instruction is input, EPROM data is read

from the address specified by the sequence above.

The read instruction acts as a direct addressing instruction, and 24 clock cycles after the input of the read instruction EPROM data is available at the A₃/Q pin. In addition, by inputting a read instruction EPROM data can be serially output 1 bit at a time. The address counter is automatically incremented by 1 every 8 read instructions.

Fig. 1 Direct addressing timing

EPROM INTERFACE

2. Indirect addressing

The timing is shown in Fig. 2. As with direct addressing, an indirect addressing instruction is input after setting of the address.

By using an indirect addressing instruction, EPROM data at the address in the address counter is output and shifted into the address counter.

In addition, when two words of ROM data are shifted into the address counter, 74 clock cycles after the input of an indirect addressing instruction the EPROM data at the set address is available as an output at the A_3/Q pin. By inputting a read instruction, ROM data can be read 1 bit at

a time in serial fashion.

The relationship between the two words of ROM data and the address shifted into the address counter is as follows.

If the address counter address is set to 00000_{16} , when an indirect addressing instruction is input, the EPROM data at that address $(D_0 D_1 D_2 D_3 D_4 D_5 D_6 D_7)_2$ and the EPROM data at the address incremented 1 $(00001)_{16}$ $(D'_0 D'_1 D'_2 D'_3 D'_4 D'_5 D'_6 D'_7)_2$ are output and shifted into the address counter, the overall address being set to $(D'_5 D'_4 D'_3 D'_2 D'_1 D'_0 D_7 D_6 D_5 D_4 D_3 D_2 D_1 D_0)_2$.

Fig. 2 Indirect addressing timing

3. Interface addressing

The M58819S is capable of addressing up to a maximum of 16K bytes of EPROM. The chip select data is $(0000)_2$.

Therefore, it is necessary to be able to specify an 18-bit address a_i ($i=0\sim 17$), the relationship between a_i and the PROM address bus being as follows.

TIMING DIAGRAMS

GENERAL-PURPOSE MOS LSIs

MITSUBISHI LSI's
M50110XP, M50115XP

30 ~ 120-FUNCTION REMOTE-CONTROL TRANSMITTERS

DESCRIPTION

The M50110XP and M50115XP are remote-control transmitter circuits manufactured by aluminum-gate CMOS technology for use in television receivers, audio equipment and other devices using infrared for transmission. The M50110XP conveys 30 different commands on the basis of a 10-bit PCM code, while the M50115XP conveys 120 different commands. These transmitters are intended to be used in conjunction with an M50111XP, M50116XP or M50117XP receiver. The X in each type corresponds to blank, A, B or C, which are respectively used for audio equipment, TV and VTR, air conditioners and other applications, or video-disk equipment.

FEATURES

Type	Remote-control function
M50110XP	30
M50115XP	120

- Single power supply
- Wide supply voltage range: 2.2V~8V
- Low power dissipation:
 Idle state ($V_{DD}=3V$): 3mW (typ)
 3 μ W (max)
- Has many functions and various uses
- Low-cost LC or ceramic oscillator used for reference frequency
- Low external component count
- Low transmitter duty cycle for minimal power consumption
- High-speed transmission

APPLICATION

- Remote-control transmitter for audio equipment, TV, VTR, air conditioners and video-disk equipment

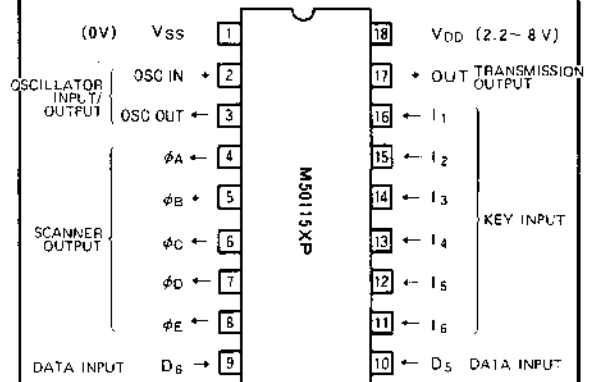

FUNCTION

The M50110XP and M50115XP transmitter circuits for infrared remote-control systems consist of an oscillator, a timing generator, a scanner, a key-in encoder, an instruction decoder, a code modulator and an output buffer. In M50110XP with a 6x5 keyboard matrix 30 commands can be transmitted by 10-bit PCM codes. In M50115XP, with a 6x5 keyboard matrix and two data inputs 120 commands can be transmitted. Oscillation is stopped when none of the keys are depressed in order to minimize power consumption.

30~120-FUNCTION REMOTE-CONTROL TRANSMITTERS

BLOCK DIAGRAM

M50110XP

M50115XP

30 ~ 120-FUNCTION REMOTE-CONTROL TRANSMITTERS

FUNCTION

Oscillator

As the oscillator is on chip, oscillation frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Fig. 1 and Fig. 2 show examples of typical oscillation circuits.

Fig. 1 An example of an oscillator (using a ceramic resonator)

Fig. 2 An example of an oscillator (using an LC network)

Setting the oscillation frequency to 480kHz (or 455kHz) will also set the signal transmission carrier wave to 400kHz (or 38kHz).

Power consumption is minimized by stopping oscillation in the oscillator when none of the keys is depressed.

Key input and data input

In the M50110XP, 30 different commands can be sent through a 6x5 keyboard matrix, consisting of inputs $I_1 \sim I_6$ and scanner outputs $I_A \sim I_E$. In the M50115XP, 120 different commands can be sent because two data inputs, \overline{D}_5 and \overline{D}_6 , are also used.

Table 2 shows the relationship between the keyboard matrix and the transmission code.

Table 1 Key code, type number and use

Key code			Type number	Use

B-14	0	1	1	1	1

30 ~ 120-FUNCTION REMOTE-CONTROL TRANSMITTERS

Transmission Commands

In the M50110XP, 30 commands can be transmitted by 10-bit PCM codes ($K_0 \sim K_2, D_0 \sim D_6$), and in the M50115XP, 120 commands can be transmitted. The first three bits $K_0 \sim K_2$, which are key codes between transmitters and receivers, correspond to type numbers and uses. Relation between key codes, type numbers and uses of remote control systems is shown in Table 1.

The next five bits $D_0 \sim D_4$ correspond to the 6x5 keyboard matrix. Relation between transmission codes and their name is shown in Table 2.

The last two bits, D_5 and D_6 , are controlled by the data inputs D_5 and D_6 . When terminal D_5 or D_6 is open or high level, data code D_5 or D_6 becomes "0", and when terminal D_5 or D_6 is low level, code data D_5 or D_6 becomes "1".

In the M50110XP, the data bits D_5 and D_6 are fixed in "0." To prevent spurious operation, the codes are designed so that there is no transmission code whose data bits $D_0 \sim D_6$ are all "0" or "1."

Transmission Coding

When oscillation frequency f_{osc} is 480kHz, transmission of data code is executed as follows: when f_{osc} is other than 480kHz, the period is multiplied by $480\text{kHz}/f_{osc}$ and its frequency by $f_{osc}/480\text{kHz}$.

A single pulse is amplitude-modulated by a carrier of 40kHz, and the pulse width is 0.25ms. Therefore a single pulse consists of 10 clock pulses of 40kHz (see Fig. 3).

Fig. 3 A single pulse modulated onto carrier (40kHz)

Fig. 4 Distinction between the bits "1" and "0"

The distinction between "0" and "1" bits is made by the pulse interval between two pulses, with an 1ms interval corresponding to "0", and a 2ms interval representing "1" (see Fig. 4).

One command word is composed of 10 bits, that is, of 11 pulses, and it is transmitted in the 24ms cycle while a matrix switch is depressed (see Fig. 5).

As mentioned above, adopting of this code means that the period during which output is high level (i.e. signal emitting LED is lit) is shorter than in continuous wave transmission. Indeed the LED is on for only half of the 11-pulse period or 1.375ms, which is 5.7% of the 24ms entire cycle. This not only saves in total power consumption, but it also improves LED reliability. That is to say, emission can be increased on the same power consumption.

30 ~ 120-FUNCTION REMOTE-CONTROL TRANSMITTERS

APPLICATION EXAMPLE (M50115XP)

M50111XP, M50116XP, M50117XP

30 ~ 120-FUNCTION REMOTE-CONTROL RECEIVER

DESCRIPTION

The M50111XP, M50116XP and M50117XP are remote control receiver circuits manufactured by aluminum-gate CMOS technology for use in television receivers, audio equipment and other applications using infrared transmission. The systems can receive 30~120 different 10-bit PCM code commands by remote control.

The M50111XP, M50116XP and M50117XP are designed for use with an M50110XP or M50115XP transmitter. The X in each type number corresponds to blank, A, B or C, which are respectively used for audio equipment, TV and VTR, air conditioner and other applications, or video-disk equipment.

FEATURES

Type	Remote-control function		Parallel outputs
	Serial data	Parallel data	
M50111XP	120	30	D ₀ ~D ₃ , STA, STB
M50116XP	120	60	D ₀ ~D ₃ , STA~STD
M50117XP	120	120	D ₀ ~D ₇ , FF

- Single power supply
- Wide power supply voltage range: 4.5V~8V
- Low power dissipation
- Low-cost LC or ceramic oscillator used for frequency reference
- Information is transmitted by pulse code modulation
- High speed reception
- Superior noise immunity — instructions are not executed unless the same code is received two or more times in succession
- Single transmission frequency (40kHz or 38kHz) for carrier wave
- Many functions and various uses
- Large tolerance in operating frequency between the transmitter and the receiver
- Can be simply connected to a microcomputer

APPLICATION

- Remote control receivers for audio equipment, TV, VTR, air conditioners, video-disk equipment and similar devices

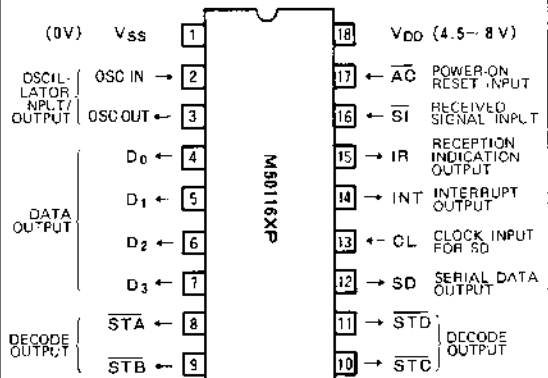

FUNCTION

The M50111XP, M50116XP and M50117XP receivers for infrared remote control systems consist of an oscillator, a timing generator, a demodulator, an error prevention circuit, a reception state decision circuit, a serial data processor, a shift register, a received signal input circuit, power-on reset circuit and other circuits. The M50111XP, M50116XP and M50117XP are designed to decode and execute instructions after 2 successive receptions of the identical instruction code. This provides positive assurance that noise will not be executed as instructions.

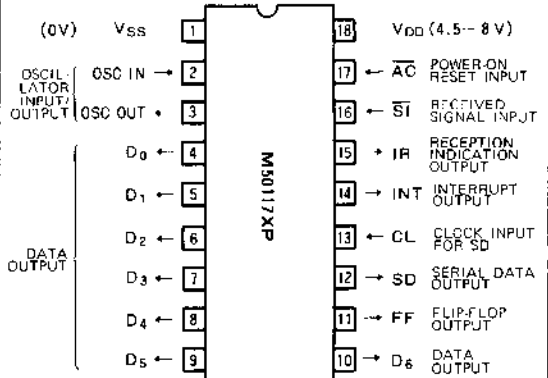

PIN CONFIGURATIONS (TOP VIEW)

Outline 16P4

Outline 18P4

Outline 18P4

With the data outputs D₀~D₆ and the decode outputs STA~STD, M50111XP can process 30 different instructions, the M50116XP can process 60 different instructions and the M50117XP can process 120 different instructions. With a serial data output SD, 120 different instructions can be processed by any of the receivers.

FUNCTION

Oscillator

As the oscillator is on chip, oscillation frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Fig. 1 and Fig. 2 show examples of typical oscillation circuit.

Fig. 1 An example of an oscillator (using a ceramic resonator)

Fig. 2 An example of an oscillator (using an LC network)

When oscillation frequency f_{osc} is 480kHz, execution is as follows:

Received Signal Input Circuit and Demodulation Circuit

The received signal, sensed by the photo detector, is amplified and an integrated signal is supplied through \overline{SI} to be processed by the received signal input circuit, and then it is sent to the demodulation circuit. In the demodulation circuit, the pulse interval of the signal is analyzed and then converted to a digital code. Fig. 3 shows the relationship between the \overline{SI} input wave form, codes and data.

Fig. 3 The relationship between the \overline{SI} input wave form, code and data

When the input pulse interval to the \overline{SI} input is 3.2 ms or longer, it will be assumed to be the end of a word, but if the interval is finally 50 ms or longer it will be accepted as the end of the command transmission and the device will be put in the idle state. In the idle state, the data outputs $D_0 \sim D_6$ and the reception indication output IR goes to low-level and the decoder outputs $STA \sim STD$ go to high-level.

Misoperation Prevention Circuit

Any signal whose low-level interval at \overline{SI} input is less than 50~100 μs is not accepted as a transmission signal.

When a pulse interval T_p is less than 0.4 ms, the misoperation prevention circuit resets to idle state to prevent an error. When all data codes $D_0 \sim D_4$ are supplied as 0 or 1, it resets to idle state.

Receive State Check Circuit

The reception indication output IR becomes high-level after receiving the same transmission code 2 or more times in succession. Therefore reception states of an instruction from the transmitter can be indicated by an LED connected to the output IR.

Reception Code, Data Output, Decode Output and Flip-flop Output

Data outputs $D_0 \sim D_6$ correspond to $D_0 \sim D_6$ of the transmission codes. When a code is 0, the data output will be low-level, and when a code is 1, the data output will be high-level, while decode outputs $STA \sim STD$ correspond to transmission codes D_4, D_5 as shown in Table 1. When the transmission codes $D_0 \sim D_6$ are 1010000, the flip-flop output FF will go to high-level, and when the codes are 0101000, the output FF will go to low-level.

Table 2 shows the relationship between key codes and type numbers, and examples of their use.

Table 1 The relationship between the decode outputs and the transmission codes D_4, D_5

Transmission code		Decode output			
D_4	D_5	STA	STB	STC	STD
0	0	L	H	H	H
1	0	H	L	H	H
0	1	H	H	L	H
1	1	H	H	H	L

Table 2 The relationship between key codes, types numbers examples of their use

Key code			Type number	Use
K_0	K_1	K_2		
0	0	0	M50111P M50116P M50117P	Remote control for audio equipment
1	0	0	M50111AP M50116AP M50117AP	Remote control for TV, VTR
0	1	0	M50111BP M50116BP M50117BP	Remote control for air conditioners and others
0	0	1	M50111CP M50116CP M50117CP	Remote control for video disk equipment

Serial Data Processor

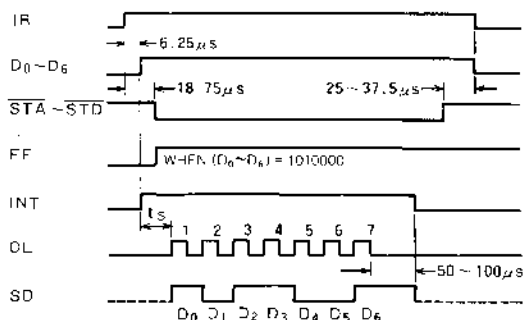

When an identical code is received twice, the reception indication output IR is turned from low-level to high-level and then after $6.25\mu\text{s}$ delay the interrupt output INT is turned from low-level to high-level (see the timing diagram). When pulses are supplied to the clock input CL for SD while the INT output is high-level, the received data are sent from the serial data output SD. These data are synchronized with the rising edge of the CL input pulses. Thus the contents of the transmission code can be read, if the SD output is decided at the falling edge of the CL input pulses.

The SD output is a three-state output, which is usually in the disabled state (high impedance). After an interrupt output INT goes to high-level, the disabled state is absolved at the first low-to-high transmission of a CL input pulses. And then the data $D_0 \sim D_6$ is serially sent, and after $50 \sim 100\mu\text{s}$ from the seventh high-to-low transmission of CL input pulses, the SD output is again put in the disabled state and at the same time the INT output goes to low-level.

Power-on Reset Circuit

Attaching a capacitor to the terminal $\overline{\text{AC}}$, the power-on reset function can be activated when power supply is applied to the IC. When the $\overline{\text{AC}}$ input is turned to low-level, the data outputs $D_0 \sim D_6$, the reception indication output IR, the interrupt output INT and the flip-flop output FF go to low-level, the decode outputs $\overline{\text{STA}} \sim \overline{\text{STD}}$ go to high-level and the serial data output SD is put in disabled state.

Timing Diagram

After the INT output becomes high-level, when the received code is not identical to the previously received code before the first fall of the CL input, the INT output is returned to low-level; at the same time the $\overline{\text{STA}} \sim \overline{\text{STD}}$ outputs become high level and the SD output become a disabled state. After the INT output goes to high-level, when received codes are not identical after the first fall of the CL input, the data $D_0 \sim D_6$ are sent and then the INT output goes to low-level after $50 \sim 100\mu\text{s}$ from the seventh fall of CL input pulses and the SD output is put in the disabled state.

The time t_s from the rising edge of the INT output to the rising edge of the CL input must be at least $6.25\mu\text{s}$.

30 ~ 120-FUNCTION REMOTE-CONTROL RECEIVER

APPLICATION EXAMPLE (M50111XP)

REFRIGERATOR CONTROLLER

DESCRIPTION

The M50250P is a semiconductor integrated circuit which uses aluminum-gate CMOS technology. It is designed for use as a refrigerator controller and provides compressor and defrosting control as well as a door alarm function.

Commercial power frequencies of 50/60Hz can be used as the reference signal.

FEATURES

- Excellent noise immunity
- Wide operating voltage range
- Built-in voltage regulating Zener diode
- Low power dissipation
- Defrosting control
- 6-minute compressor stop control
- Compressor startup control
- Door alarm control

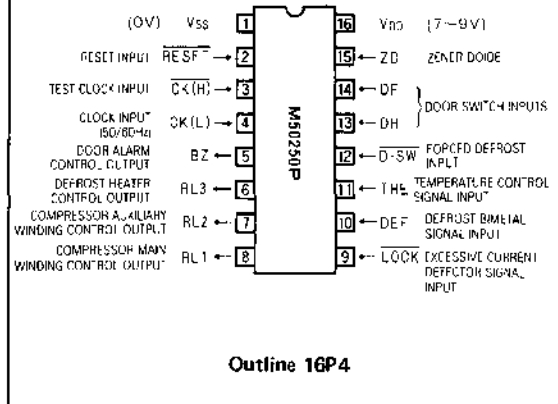

APPLICATIONS

Refrigerator and compressor control

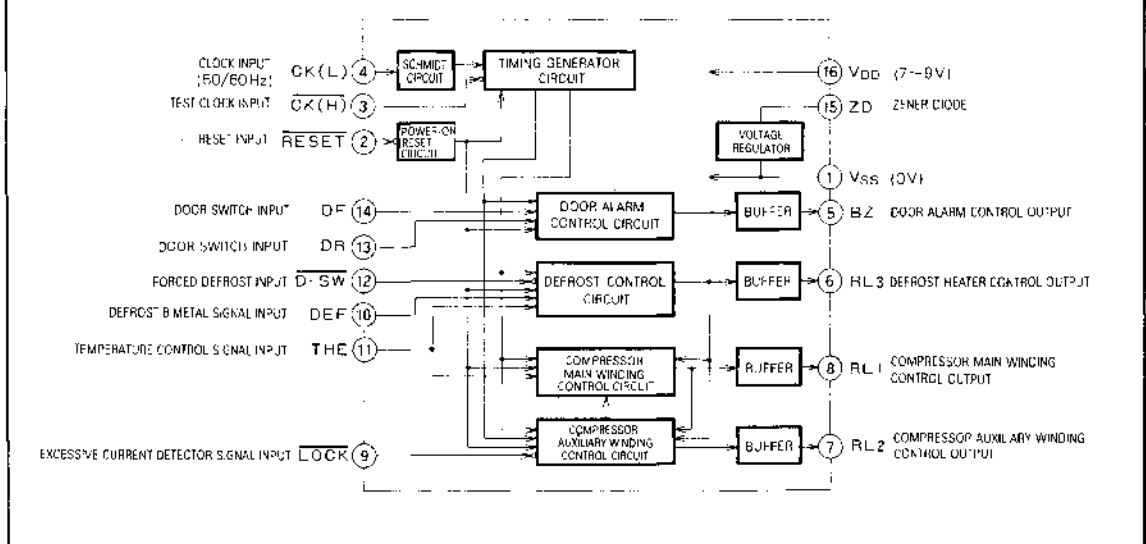

FUNCTION

The M50250P is a refrigerator control IC which uses commercial power frequencies (50/60Hz) as a reference signal to provide defrost control, compressor 6-minute stop control, compressor startup control, and door alarm control functions.

PIN CONFIGURATION (TOP VIEW)

BLOCK DIAGRAM

11

REFRIGERATOR CONTROLLER

FUNCTIONAL DESCRIPTION

For the purposes of the description below, the times shown apply if a 60Hz signal is applied to the CK(L) pin. These times are multiplied by 1.2 for a 50Hz input frequency.

DEFROST CONTROL

The amount of time that the temperature control signal input THE is high is counted until the total reaches 7.40 hours, at which time if the defrost bimetal signal input DEF is low, the defrost heater control output RL3 goes high. When the defrost operation is completed, the DEF input goes high and the RL3 output goes low.

In addition, by setting the forced defrost input $\overline{D-SW}$ to low, forced defrosting is performed even if 7.40 hours have not elapsed.

COMPRESSOR CONTROL

1) 6-Minute Stop Function

As a protective feature for the compressor, if the compressor is temporarily stopped, a 6-minute timer operates. Until this 6-minute time limit is reached, the compressor remains in the stopped condition. However, when power of M50250P is supplied the compressor operates immediately.

2) Startup Control

Whenever power is supplied or the 6-minute timer period elapses, when the temperature control signal input THE is high and the RL3 output is low, the main winding control output RL1 goes high and the compressor operates. At this startup time, if the excessive current detector signal input \overline{LOCK} goes low, the auxiliary winding control output RL2 becomes high and the compressor goes into two-phase operation.

When the \overline{LOCK} input goes from low to high and the high period lasts for 0.5 seconds (more precisely 0.495 ~ 0.5 seconds), the RL2 output goes from high to low, and the compressor goes into single-phase operation.

3) Excessive Current Detector Signal

When the compressor is started-up, a 10-second timer is reset, and the clock is started. Within 5 seconds (or more precisely 4 ~ 5s) of this startup, the \overline{LOCK} input goes low and the RL2 output goes high whereupon two-phase operation begins. The 10-second timer is again reset and the clock begins running. If the \overline{LOCK} input does not remain high for at least 0.5s, after 5 seconds the 6-minute stop function operates and the compressor is stopped.

If the \overline{LOCK} input goes low within 5 to 10 seconds of the compressor startup, the 6-minute stop function operates.

If the \overline{LOCK} input goes low after more than 10 seconds after the compressor startup, the RL2 output

goes high, the 10-second timer is reset and the clock begins running. That is, the initial startup condition is restored.

DOOR ALARM CONTROL

When either the DF or DR door switch inputs or both the inputs are high for more than 15 seconds (more precisely 14.9 ~ 14.95), the buzzer alarm control output BZ goes high for 0.15 seconds and until both DF and DR go low, this output alternates between 1.5 seconds low and 0.15 seconds high.

POWER ON RESET FUNCTION

By connecting a capacitor to the \overline{RESET} pin, an automatic reset can be performed when power is applied to the M50250P.

When this automatic reset operates, the timers and flip-flops controlling the outputs are reset or set appropriately.

However, to ensure proper power on reset operation, the supply voltage V_{DD} rising edge should be at least 10ms removed from the rising edge of the \overline{RESET} input.

REGULATED POWER SUPPLY

An internal Zener diode is used to provide simple regulated power supply. In addition, the Zener diode pin (ZD) is independent of the supply voltage pin (V_{DD}) making it useful as the overall system regulated power supply.

M50405P	SILICON GATE CMOS	32.768kHz	16ms	2048 × 16 × 1Hz

FEATURES

- Low power consumption
 M50401P, M50402P 25µA (typ)
 M50403P, M50404P, M50405P 2µA (typ)
- Low operating voltage 1.1V (min)

APPLICATIONS

- Alarm clocks
- Precision clocks for electronic equipment
- Frequency dividers for electronic equipment

PIN CONFIGURATION (TOP VIEW)

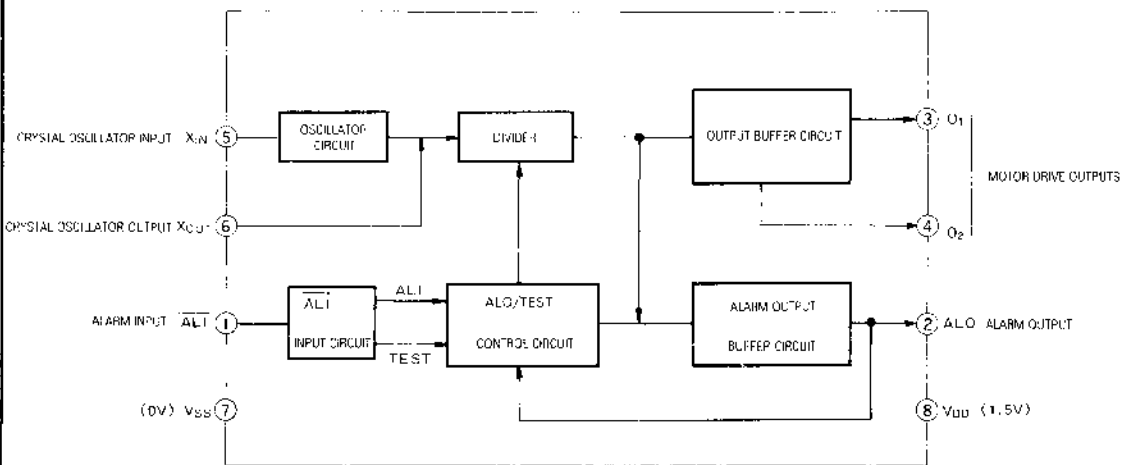

Outline 8P4

FUNCTION

The M50401P, M50402P, M50403P, M50404P and M50405P are CMOS ICs designed for use in crystal-controlled clocks. They consist of a crystal controlled oscillator, dividers, alarm bell drive output buffer circuit, and motor drive output buffer circuits. They are designed for use with standard 4,1943MHz or 32.768kHz clock reference crystals, and perform the required divisions to drive a stepping motor.

BLOCK DIAGRAM

M50401P, M50402P M50403P, M50404P, M50405P

CMOS ANALOG CLOCK CIRCUITS

FUNCTIONAL DESCRIPTION OSCILLATOR CIRCUIT

A crystal oscillator element is connected between X_{IN} (oscillator input) and X_{OUT} (oscillator output) pins and capacitors are connected to ground from each of these pins.

OUTPUT BUFFER CIRCUIT

The output buffer circuit is an amplifier capable of producing a drive current from the output of the last divider stage. The O_1 output is 1-second shifted from the O_2 output. By connecting these to a stepping motor, the 1-second hand steps can be generated.

ALARM INPUT (\overline{ALI})

By setting the \overline{ALI} pin to the value of V_{SS} , an alarm waveform is output from ALO. In addition, by setting the \overline{ALI} pin to an intermediate value, a test state is achieved, and a 2048Hz signal is continuously output from ALO. If an intermediate level is applied to \overline{ALI} while X_{IN} and X_{OUT} are set to V_{SS} , the last 12 stages of dividers can be fed from the ALO signal.

ALARM OUTPUT BUFFER CIRCUIT

The alarm output buffer circuit generates a drive signal for a piezoelectric element or magnetic speaker. The alarm output signals are 50% duty cycle 2048Hz, 2Hz, and 1Hz signals for the M50401P and M50403P, and 50% duty cycle 2048Hz, 8Hz, and 1Hz signals for the M50402P and M50404P. And 50% duty cycle 2048Hz, 16Hz and 1Hz signals for the M50405P.

CMOS ANALOG CLOCK CIRCUITS

APPLICATION EXAMPLE

CMOS LCD DIGITAL ALARM CLOCK CIRCUITS

DESCRIPTION

The M58412P and M58413P CMOS aluminum-gated LSIs serve 4-digit liquid-crystal display (LCD) digital alarm clocks employing quartz oscillators of 4.2 MHz and 32 kHz respectively.

FEATURES

- Low current consumption. Under ordinary conditions, M58412P consumes 30 μ A at an oscillator frequency of 4.2 MHz and $V_{SS(1)}$ level of -1.5V, while M58413P consumes 2 μ A at 32 kHz and $V_{SS(1)}$ of -1.5V.
- The 12-hour clock-display function shows AM or PM hours and minutes; the 24-hour system shows hours and minutes alone.
- Separate switches enable independent setting of hours and minutes.
- Five alarm output signals are provided: a continuous alarm-bell signal, intermittent alarm-bell signal, external bell-oscillator-circuit-drive signal, external electronic-apparatus switching signal, and 12 min or 120 min DC signal.
- The alarm bell output can continue for up to 12 min.
- A 10 min 'snooze' function is incorporated.
- The LSI causes the whole display to flash on and off when battery voltage drops below the specified level.
- Two LCD mark outputs are provided: alarm and sleep. The display offers immediate indication of the function in current operation.
- The LSIs enable sleep and auto-recording timers to be set at any time during a 59-minute period. A 120-minute output mode is also available with auto-recording timers.

PIN CONFIGURATION (TOP VIEW)

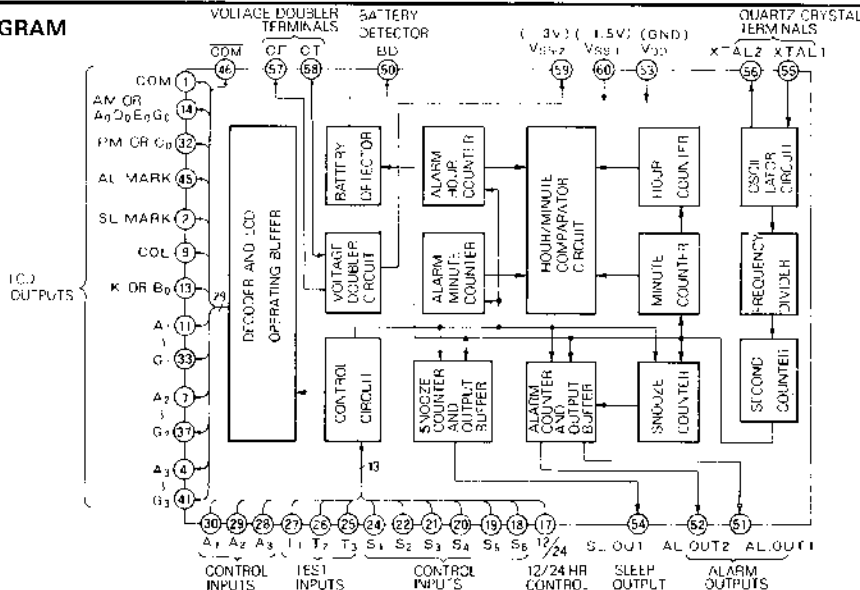

APPLICATIONS

- Alarm clocks with a 'snooze' function
- Sleep timers
- Travel watches
- Switching timers for electronic apparatus
- Auto-recording timers for audio equipment

FUNCTION

Normal clock, alarm clock, 'snooze' timer, sleep timer, electronic-apparatus switching timer, and audio-equipment auto-recording timer functions are provided by the oscillator and frequency divider (4.2 MHz for M58412P and 32 kHz for M58413P).

OPERATION

The following figures and tables show the LCD-electrode

arrays on the LCD panel, the segment codes, and the display modes.

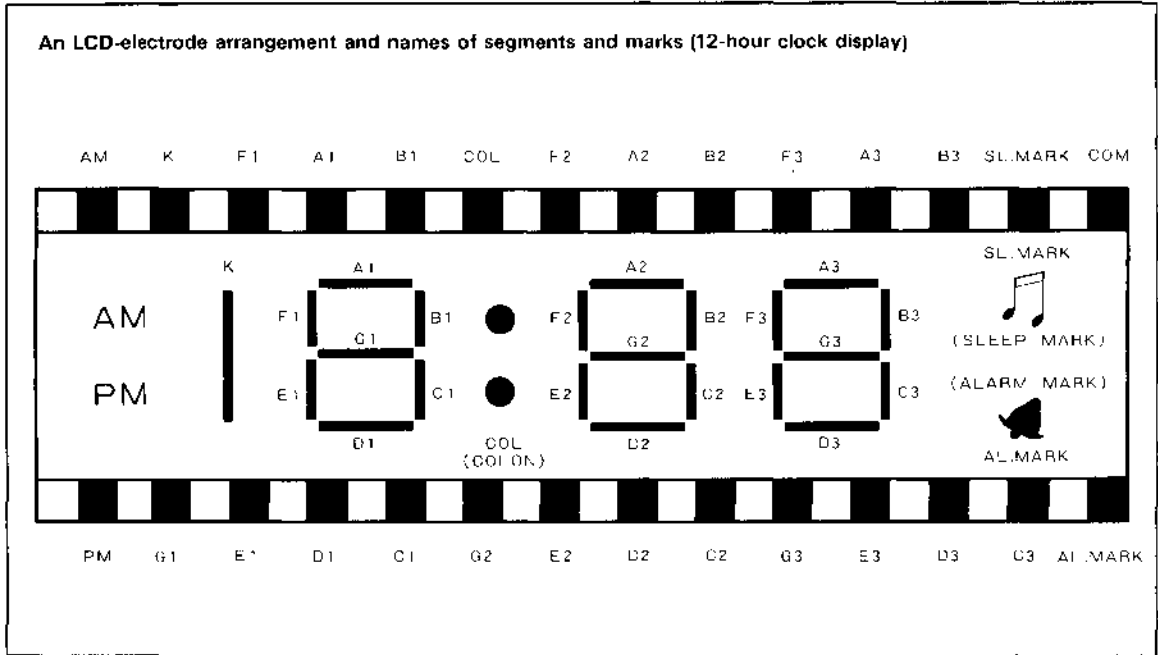

Table 1 12-Hour Clock Display

Mode	Display	Meaning of mark display
Normal clock ordinary display		<ul style="list-style-type: none"> Sleep timer is in operation Alarm time is being set
Alarm		<ul style="list-style-type: none"> Alarm time is displayed; adjustment possible
Sleep time		<ul style="list-style-type: none"> Sleep time is displayed; adjustment possible Alarm timer is being set

Note 1. The symbol indicates a 2sec on-off flash.

CMOS LCD DIGITAL ALARM CLOCK CIRCUITS

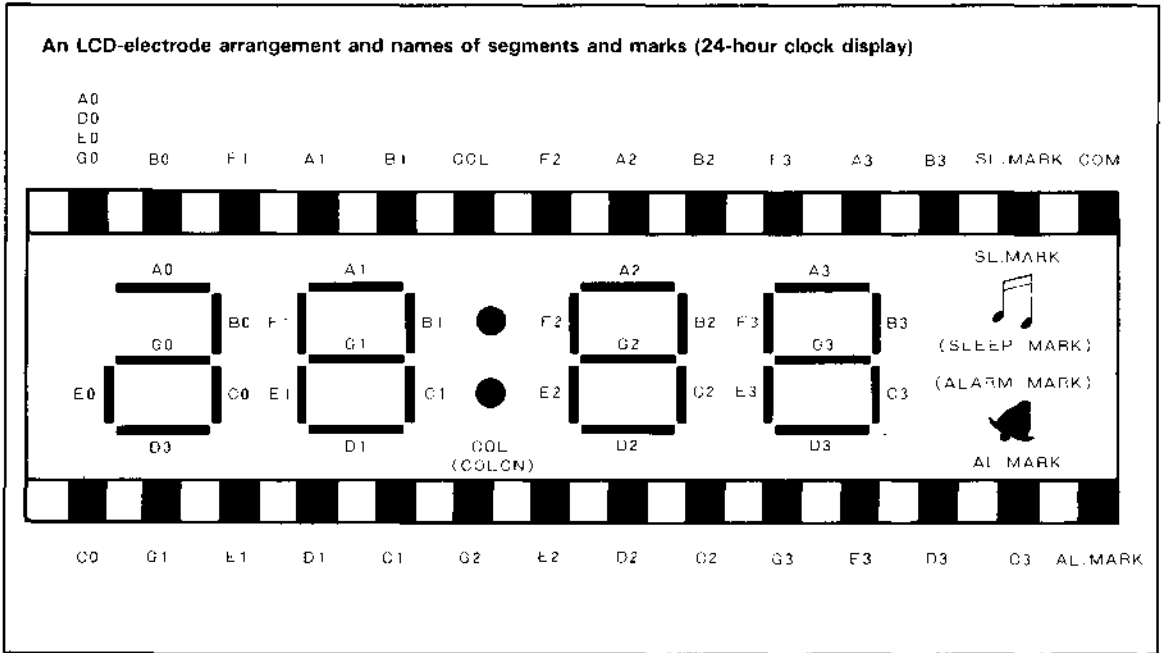

Table 2 24-Hour Clock Display

Mode	Display	Meaning of mark display
Normal display	20:56  	<ul style="list-style-type: none"> → Sleep timer is in operation → Alarm timer is being set.
Alarm display	7:00 	<ul style="list-style-type: none"> → Alarm time is displayed, adjustment possible
Sleep-time display	30  	<ul style="list-style-type: none"> → Sleep time is displayed, adjustment possible → Alarm timer is being set

Note 1 : The symbol  indicates a 2sec on-off flash.

CMOS LCD DIGITAL ALARM CLOCK CIRCUITS

FUNCTIONS OF INPUT AND OUTPUT PINS

Input Pins

The potential drop to the level of $V_{SS(1)}$ ($-1.5V$) or $V_{SS(2)}$ ($-3V$) achieved inside the LSI ensures that all the input pins are used in the floating-state condition. The input pins A_1 , A_2 , A_3 , S_1 , and S_6 have the potential of $V_{SS(1)}$, while all the other input pins have $V_{SS(2)}$. Signal input requires the use of the $V_{DD(GND)}$ level for all input pins.

S₁ Pin

Every push of the S_1 push-button switch advances 1 minute in normal clock-time adjustment, alarm-time setting and sleep-time setting. Raising to the hour digit is prohibited in this operation. In the normal-clock ordinary-display mode, the S_1 pin also serves as a start/stop input pin for the sleep timer. A sleep mark flashing on and off displays the sleep timer's operation. It will disappear when the sleep timer stops operation, or as soon as the time initially set on the sleep timer is reached.

S₂ Pin

Every push of the S_2 push-button switch advances 1 hour in normal clock-time adjustment and alarm-time setting. In the normal-clock ordinary-display mode, the S_2 pin also serves as an input pin to bring the sleep output to the $V_{SS(1)}$ level. This function makes it possible to switch off a radio or other electronic apparatus before the time initially set on the sleep timer is reached.

S₃ Pin

When the A_3 pin is held at the V_{DD} level, a momentary switch should be used to enable the input with the S_3 -pin potential to change momentarily to the V_{DD} level. Pushing the S_3 switch changes the mode cyclically in the sequence: normal-clock ordinary display; alarm-time display (alarm-time setting is possible); and sleep-time display (sleep-time setting is possible). However, when the A_3 pin is in the floating state (the inside-LSI potential is $-1.5V$), it is recommended to use a lock switch to retain the V_{DD} level at the S_3 pin. While S_3 -pin potential is kept at V_{DD} , the alarm-time display mode is effective (alarm-time setting is possible). Disconnecting the S_3 pin restores the normal-clock ordinary-display mode. The sleep-timer mode cannot be used when the A_3 pin is in the floating state. In this case, however, there are convenient applications (for travel watches, etc.) free from the problem of alarm-time lags behind the set time which sometimes arise from the use of momentary switches due to their accidental operation.

S₄ Pin

When the normal-clock normal-display mode of the basic clock is effective, maintaining this pin at the V_{DD} level causes entry to the normal-clock time-adjustment mode. After time adjustment with the S_1 and S_2 pins, clock operation starts with the '00' second of the adjusted time as soon as S_4 is disconnected from the V_{DD} level.

S₅ Pin

This pin is used to provide alarm-timer set input. Maintaining this input pin at the V_{DD} level causes the alarm mark to stay on. When the normal clock time coincides with the alarm time, two types of alarm output, AL. OUT1 and AL. OUT2, generate alarm signals. (The alarm signal with a pulse width of 250ms is generated only once after the coincidence takes place.) When cancellation of the alarm signal is desired, disconnecting the S_5 pin from the V_{DD} level causes both the alarm mark and alarm signal to disappear. No alarm signals will be generated when the normal clock time coincides with the alarm time, unless the S_5 pin is at the V_{DD} level.

S₆ Pin

This pin has three functions: 'snooze' timer-setting input, sleep-timer resetting input, and LCD lamp switching at night. When an alarm signal is generated in the normal-clock ordinary-display mode, bringing the S_6 potential momentarily to V_{DD} stops the alarm signal for a moment and generates it again after 9~10 minutes. (The 1-pulse alarm signal with a 250ms pulse width cannot be generated again.) The 'snooze' function can be repeated at every signal input made to the S_6 pin. However, it does not operate after an alarm signal has continued for 12 minutes. This function is useful for 'snooze' clocks and other applications.

When no alarm signals are generated in the normal-clock ordinary-display mode, or when the 'snooze' function is not in operation, bringing the S_6 potential momentarily to V_{DD} makes it possible to reset the sleep time to 59 minutes and to make the sleep output level V_{DD} . This means that when a stereo or other apparatus connected is to be switched off after 59~60 minutes, it is unnecessary to use the 59 minute setting in the sleep-time display mode: It is only necessary to push the S_6 push-button switch and then push the S_1 -pin start button, giving great ease of operation. The S_6 pin, at a potential level of $-1.5V$, also serves as an LCD lamp power terminal at night (See Fig. 1). Care should be taken, however, over the fact that every time the LCD lamp is turned on a 'snooze' timer set input or sleep-timer/reset input is entered.

Fig. 1 An LCD lamp circuit

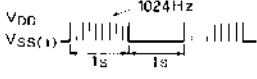

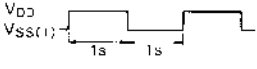

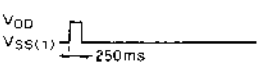

CMOS LCD DIGITAL ALARM CLOCK CIRCUITS

A₁ and A₂ Pins

AL. OUT1 pin alarm output in different modes is generated in accord with a combination of the A₁- and A₂-pin potentials. Table 3 shows four modes and their applications.

Table 3 AL. OUT1 Pin Alarm Output

A ₁	A ₂	Output waveform of AL. OUT1	Main applications
N.C.	N.C.		Operation of bells, buzzers and other sound sources without oscillator circuits (intermittent sound)
V _{DD}	N.C.		Operation of sound sources with oscillator circuits (intermittent sound)
N.C.	V _{DD}		Operation of sound sources without oscillator circuits (continuous sound)
V _{DD}	V _{DD}		Switching of electronic apparatus

A₃ Pin

This pin controls mode shifts between normal-clock ordinary-display mode, alarm-time display mode, and sleep-time display mode by the S₃ pin. When the A₃ pin is not connected (N.C.), it operates in the alarm-time display mode so long as the S₃ pin is at the V_{DD}-level. When the S₃ pin is disconnected from the V_{DD} contact, the S₃ pin enters the normal-clock ordinary-display mode, but not the sleep-time display mode. When the A₃ pin is at the V_{DD} level, mode shifts occur cyclically in the sequence: normal-clock ordinary display; alarm-time display; sleep-time display; and normal-clock ordinary display, each time the S₃ pin is momentarily at the V_{DD} level.

12/24 Pin

Bringing the 12/24-hour pin to the V_{DD} level turns the 12-hour cycle display into the 24-hour cycle display.

T₁, T₂ and T₃ Pins

The T₃ pin is a clock-input pin for high-speed test use. Combinations of T₁ and T₂ pin potentials control the test mode and options, as shown in Table 4.

Table 4 Test Mode

T ₁	T ₂	Mode
N.C.	N.C.	Normal operation
V _{DD}	N.C.	Normal clock ordinary display with the colon kept ON (without colon on/off flash)
N.C.	V _{DD}	The counter is reset and 12:00 AM (0:00 for 24-hour cycle) is displayed in the normal-clock ordinary display mode. Here, the alarm time is 12:00 AM (0:00 for 24-hour cycle) and the sleep time is 59 minutes
V _{DD}	V _{DD}	Carryover from the minute to the hour digits is prohibited. The common output is held at the V _{SS(2)} level, and the segment and mark output for display is at the V _{DD} level. High-speed testing is possible.

OUTPUT PINS

Output Pins for Segments, COM, $\overline{\text{COM}}$ AL. MARK, and SL. MARK

The COM output pin common signal has a frequency of 32Hz. Segments and mark output pins which are not displayed give common signals, while segments and mark output pins displayed give inverse-phase signals of common signals. The $\overline{\text{COM}}$ output is used for permanently-displayed segments or marks.

AL. OUT1 (Alarm output 1) Pin

When the normal-clock ordinary-display time coincides with the alarm time, alarm signals with the waveforms shown in Table 3 are generated at the AL. OUT1 pin for 12 minutes. The 250 ms pulse-width alarm output, however, is given only once after the coincidence.

Coincidence in the alarm-time display mode causes the AL. OUT1 to be given for one minute. When they coincide in the normal-clock time-adjustment mode, continuous alarm signals are generated until the time is advanced.

AL. OUT2 (Alarm Output 2) Pin

When both the A₁ and A₂ pins are at the V_{DD} level (when the AL. OUT1 is the 250 ms pulse-width alarm output), the AL. OUT2 pin gives a DC output for 110~120 min. In cases of the alarm-time minute digit set to integral multiples of 10 minutes from 10 to 50 min., a DC output is sent out for 120 min. This signal is useful for controlling electronic apparatus for 2-hour auto-recording. When both the A₁ and A₂ pins are at other than the V_{DD} level, a DC output is given for 11~12 min by the AL. OUT2 pin.

Fig. 2 Alarm output waveforms

11

CMOS LCD DIGITAL ALARM CLOCK CIRCUITS

SL. OUT (Sleep Output) Pin

This pin can be used not only for sleep timers but also for turning on and off radios, TVs, cassette decks, and VTRs. In the normal-clock ordinary-display mode, the SL. OUT pin can be brought to the V_{DD} level, i.e., the switch-on stage, by starting the sleep timer with the S_1 pin, or by bringing the S_6 pin potential momentarily to V_{DD} after 12 minutes' issuance of the alarm signal or when the 'snooze' function is not in operation. As soon as the sleep time becomes 59 minutes in the normal-clock ordinary-display mode (the sleep timer does not display the time elapsed), or by bringing the S_2 -pin potential momentarily to V_{DD} in the normal-clock ordinary-display mode, the switch-off state, i.e., the $V_{SS(1)}$ level, holds. Fig. 3 shows SL. OUT-pin output waveforms: (1) when the switched-off state is entered at the sleep time set; (2) when the timer is stopped after the start of the sleep timer and started again; and (3) when the switched-off state is entered before the sleep time set. Input pins to be used are shown in parentheses. When the sleep output is turned to the V_{DD} level by using the S_6 pin, this level is maintained unless the sleep timer is started with the S_1 pin. Use of the SL. OUT pin as a maximum 60-minute auto-recording pin requires that both the A_1 and A_2 pin potentials are set to V_{DD} and the AL. OUT1 pin is connected with the S_1 pin as shown in Fig. 7. In this case, sleep output assumes the V_{DD} level when the alarm time coincides with the normal time.

Fig. 3 SL. OUT output waveforms

POWER CIRCUITS

V_{DD} , $V_{SS(1)}$, $V_{SS(2)}$, CF, and CT Pins

The electrical power supply is a 1.5V battery ($=V_{DD}-V_{SS(1)}$). Use of 0.1 μ F condensers between the CF and CT pins and between the $V_{SS(2)}$ and $V_{DD(GND)}$ pins gives voltage about double the power voltage, making possible direct operation of the LCD.

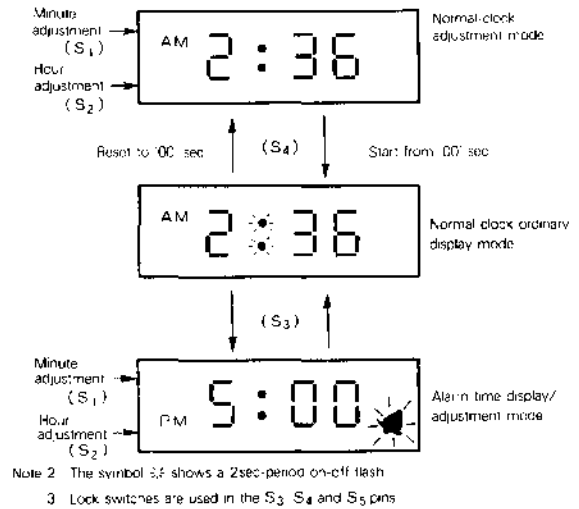

BD (Battery Detector) Pin

By connecting a resistor between the BD and $V_{SS(1)}$ pins which has a proper temperature characteristic and a resistance between 15k Ω and 750 Ω , the segments and marks displayed flash on and off in a 2sec period, a visual reminder of the necessity to replace the battery, when the battery

voltage drops to any specified level in the detectable voltage range of $V_{DD}=-1.2\sim-1.5V$. This flashing can be stopped by making the S_6 potential momentarily V_{DD} . However, it will start again at the next sampling time (max. one minute later) until the battery is replaced.

APPLICATION EXAMPLES

Fig. 6 An alarm clock with 'snooze' and sleep functions

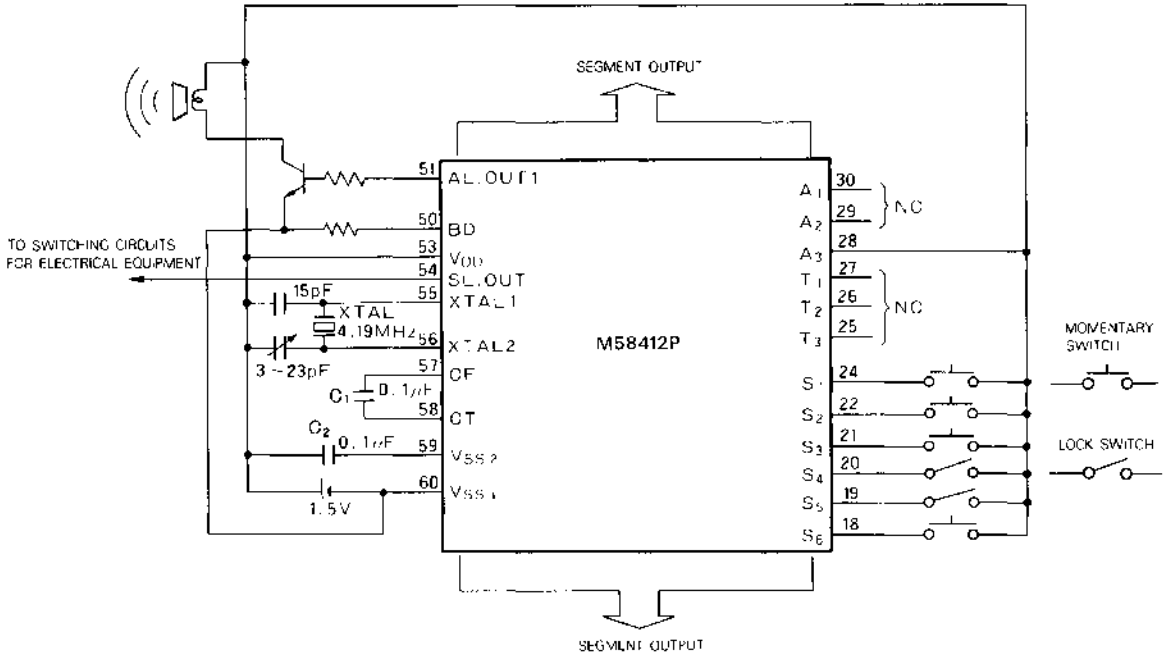

Fig. 7 An alarm clock with 'snooze' and auto-recording functions

Note 7 The circuit of Fig. 6 gives intermittent alarm-bell tones.

8 The circuit of Fig. 7 gives continuous alarm-bell tones.

9 Use of Type M58413P in Fig. 6 and Fig. 7 requires the employment of a 32kHz quartz oscillator and a 5 ~ 35pF variable condenser.

Note 10 Use is made of AL_OUT2 for 110 ~ 120 minute fixed-time auto-recording output and of the SL_OUT pin for maximum 60 minute non-fixed-time auto-recording output.

MITSUBISHI LSIs
M58435P
M58437-001P

CMOS ANALOG CLOCK CIRCUITS

DESCRIPTION

This family of CMOS circuits is particularly suited for crystal-controlled clocks where induction motors or stepping motors are used.

Type	Process	Crystal oscillator	Motor	Alarm sound
M58435P	Silicon-gate CMOS	4.1943MHz	Stepping motor	1024Hz
M58437-001P	Aluminum-gate CMOS	32.768KHz	Stepping motor	4096 × 8 × 1Hz

FEATURES

- Low power dissipation:
 - M58435P: 30μA (typ)
 - M58437-001P: 2μA (typ)
- Low voltage operation:
 - M58435P: 1.2V (min)
 - M58437-001P: 1.1V (min)
- Direct drive of ceramic resonator (M58437-001P only)

APPLICATIONS

- Crystal-controlled alarm clock
- Precision timepiece for electronic apparatus
- Frequency divider for electronic apparatus

PIN CONFIGURATION (TOP VIEW)

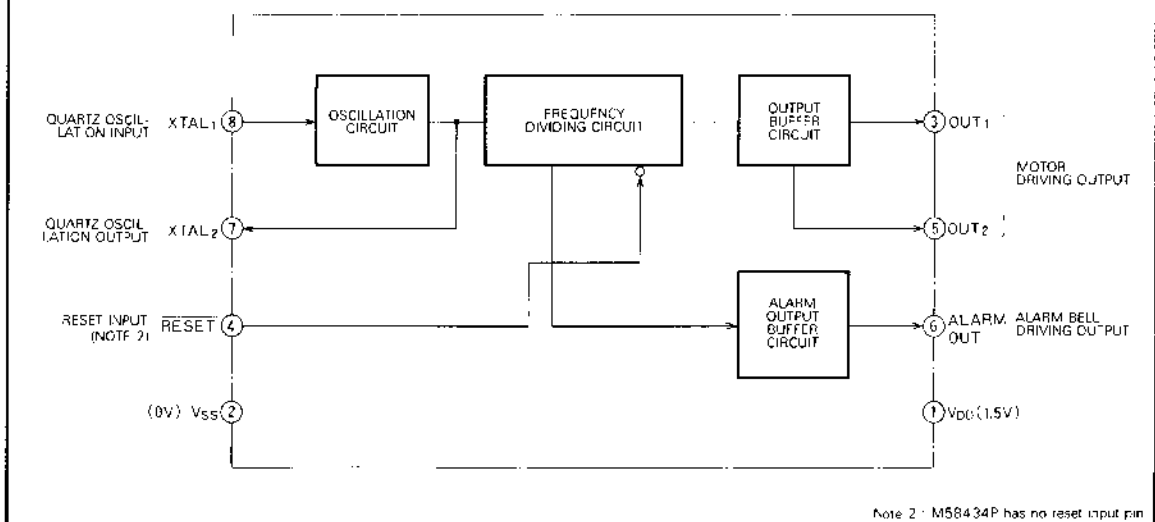

Note 1. This pin is non-connected for M58434P.

Outline 8P1 (M58435P)
(M58437-001P)

FUNCTION

Circuitry consists of an oscillator, frequency divider, bridge-type driver circuit for an induction motor or a stepping motor (M58435P, M58437-001P), and an alarm bell driver circuit. The oscillator frequency is 32.768kHz for the M58437-001P and 4.1943 MHz for the other types.

BLOCK DIAGRAM

Note 2: M58434P has no reset input pin

FUNCTIONAL DESCRIPTION

Oscillation Circuit

This circuit is completed by connecting a crystal between XTAL₁ (oscillation input) and XTAL₂ (oscillation output) and capacitances between both terminals and GND.

Motor Driver Circuit

This circuit amplifies motor driving current at the output frequency of the last divider. In M58435P, Outputs OUT₁ and OUT₂ are always in a mutually reversed phase, while in the M58437-001P, OUT₁ has a wave-form delayed 1sec from OUT₂. It is realized by continuous movement or stepped movement when the M58434P is connected to an induction motor (M58434), to a stepping motor with series-connected capacitance (M58435P) or a stepping motor (M58437-001P). The size of the capacitance for M58435P is determined by the total current consumption and the required motor torque, and with a 47μF capacitor, SUM-2 manganese dry cells will last for about one year.

Reset Input (RESET)

When the RESET terminal of the M58435P is held at V_{SS} level, outputs OUT₁ and OUT₂ hold their current states of

that time, and invert 0.97~1.0sec after the reset terminal is released from the V_{SS} level. In the M58436-001P and M58437-001P, OUT₁ and OUT₂ go to the V_{SS} level, and 0.97~1.0sec after the reset terminal is released from V_{SS} level, a 31ms pulse is generated from the output opposite to the one that emitted a 31ms pulse immediately before the reset. If the RESET terminal is connected with the V_{SS} during the 31ms pulse, the reset will be started completely after the pulse ends. This prevents inadvertent interruption of complete action of the motor owing to the reset function. The M59434P has no reset function.

Alarm Output Buffer Circuit

This circuit consists of an N-channel open-drain MOS transistor and generates a signal to drive a ceramic resonator or magnetic speaker (see p. 10-14). The alarm output is a 1024 Hz signal, with a duty cycle of 50% for M5843P and M58435P, and burst signals of 4096Hz, 8Hz, and 1Hz, each of 50% duty, for M58437-001P. Direct drive of the ceramic resonator by M58437-001P is possible because of the high alarm output breakdown voltage.

MITSUBISHI LSIs

M58478P, M50121P, M50122P

17-STAGE OSCILLATOR/DIVIDER

DESCRIPTION

The M58478P, M50121P, and M50122P are semiconductor integrated circuits which use aluminum-gate CMOS technology. The M58478P produces a frequency of 1/59719 or 1/88672, the M50121P produces a frequency of 1/58239 or 1/61425, and the M50122P produces a frequency of 1/86118 or 1/92077 of the input frequency.

FEATURES

- Usable as a crystal oscillator circuit
- Capable of handling small-amplitude input signals as low as 0.3V_{pp}
- Frequency-dividing ratio selected through pin N
- Reset function
- Produces a shaped-waveform output of the same frequency as the input signal or oscillation output
- Derives a vertical scanning frequency from TV color subcarrier

APPLICATION

Frequency divider for VTR equipment.

FEATURES

The M58478P, M50121P, and M50122P have a programmable counter consisting of a 17-stage binary frequency divider which provides one of two frequency-dividing ratios as selected by the state of the N input.

BLOCK DIAGRAM

17-STAGE OSCILLATOR/DIVIDER

FUNCTIONAL DESCRIPTION

Crystal Oscillator

A crystal oscillator is configured by connecting a quartz resonator element between pins OSC IN and OSC OUT, and capacitances C_{L1} and C_{L0} between the two pins and V_{SS} (the feedback resistor included, on the chip). A built-in amplifier at the OSC IN pin enables even small amplitude signals to be input through a coupling capacitor.

Output Frequency

The frequency dividing ratio depends on the state of the N input. Table 2 summarizes the frequency dividing ratios and duty cycles as they are related to this N input. An example of a divided frequency output waveform is shown in Fig. 1.

Special Frequency Dividing Ratios

It is possible to modify the frequency dividing ratios on special order. By changing one of the manufacturing processes, the data input of the programmable counter consisting of a 17-stage binary divider can be changed to enable any frequency-dividing ratio from 5 to 131071 ($= 2^{17}-1$).

Table 2 Frequency-Dividing Ratios

Type	State of the N input	Frequency-dividing ratio	Divided frequency output low-level period	Divided frequency output high-level period
M58478P	H	59719	26953	32766
	L	88672	55906	32766
M50121P	H	58239	25473	32766
	L	61425	28659	32766
M50122P	H	86116	53352	32766
	L	92077	59311	32766

Fig. 1 Waveforms of divided-frequency output (for the M58478P)

A shaped-waveform output of the same frequency as the input signal or oscillation frequency is available at the TUNER output.

Reset Function

When the $\overline{\text{RESET}}$ input is changed from high to low (edge triggered, active low input), the output OUT changes to low.

Pull-up Resistance

There are resistors at the N and $\overline{\text{RESET}}$ inputs, eliminating the need for external resistors. The standard resistance of the pull-up resistor is 20k Ω .

Frequency Dividing Ratio

The frequency-dividing ratio is determined by the data input of the programmable counter consisting of a 17-stage binary divider.

CMOS COUNTER/TIMERS

DESCRIPTION

The M58479P and M58482P are electronic timer ICs developed by aluminum-gate CMOS technology. Use of these ICs makes possible timer devices without mechanical elements, which have reduced power dissipation, superior reliability, and higher noise immunity. The M58479P is specifically designed for high noise immunity while the M58482P particularly features low power dissipation.

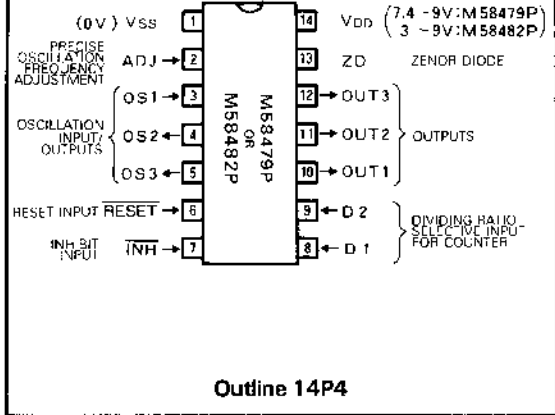

FEATURES

- Low power dissipation
 M58479P: 2mW (typ), 7.5mW (max)
 M58482P: 200μW (typ), 750μW (max)
- Superior noise immunity
- Single power supply with a zenor diode
- Internal RC oscillator
- Precise oscillation frequency regulating capability
- Extremely broad time-delay range (50ms~4800h)
- Time-delay settable to 10, 60, or 600 times fundamental time (1024 times oscillation period)
- M58479P has automatic-reset function during power engagement
- Built-in reset and inhibit functions
- Residual time display possible by adding Mitsubishi's M53290P and M53242P IC

APPLICATIONS

- Electronic timer or counter with broad time-delay range (50ms~4800h)

PIN CONFIGURATION (TOP VIEW)

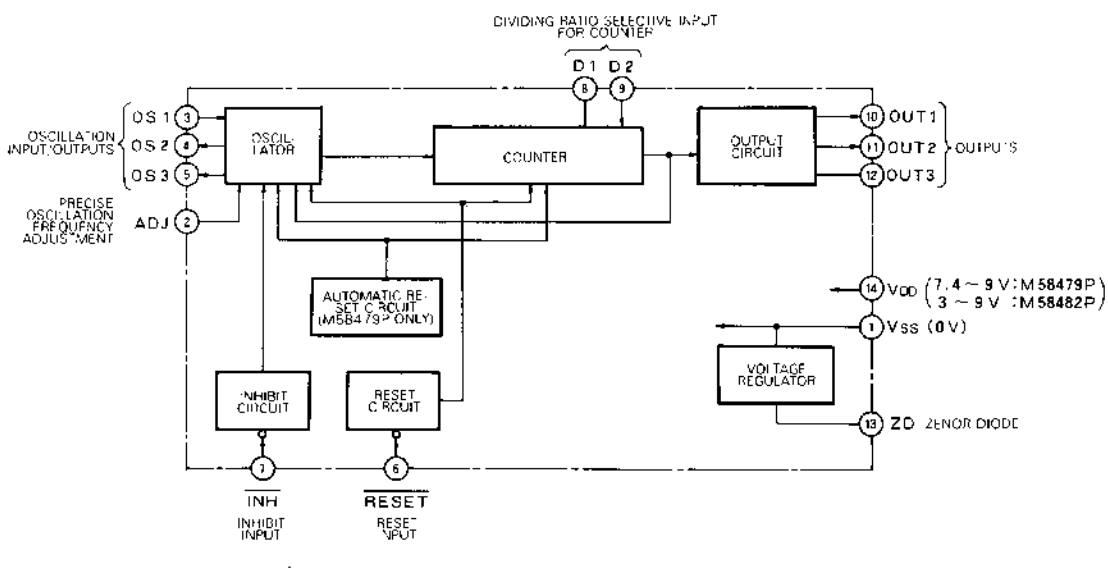

Outline 14P4

FUNCTION

These devices make possible extremely long clock performance, by counting pulse signals from the RC oscillator. It has precise oscillation frequency adjustment, automatic-reset, reset, and inhibit functions.

There are three outputs. When the time duration is up, OUT1 turns from low to high and OUT2 from high to low. OUT3 can be connected to M53290P and M53242P TTLs for residual time display.

BLOCK DIAGRAM

FUNCTIONAL DESCRIPTION

Voltage Regulator

A zenor diode is on-chip, making it easy to obtain a constant voltage regulator circuit. Since the zenor diode terminal (ZD) is independent of the power terminal (V_{DD}), it can be used as a constant voltage power supply for the total system.

Oscillator

Oscillation is obtained by connecting an external resistor (feedback resistor R_{FC}) between terminals OS1 and OS3 and an external capacitor (oscillation capacitor C_{FC}) between terminals OS1 and OS2. The values of the external resistor and capacitor can then be changed to vary the oscillation period and thus change the time delay. Oscillation period T_0 is obtained by the following equation:

$$T_0 = -R_{FC} \cdot C_{FC} \left(\left| n \frac{V_{TR}}{V_{DD} + V_{BE}} \right| + \left| n \frac{V_{DD} - V_{TR}}{V_{DD} + V_{BE}} \right| \right) \dots (1)$$

Where,

- R_{FC} : Resistance of external resistor
- C_{FC} : Capacitance of external capacitor
- V_{TR} : Transition voltage of the first inverter in the oscillation circuit
- V_{DD} : Supply voltage
- V_{BE} : Forward rising voltage of the diode in terminal OS1 (0.3~0.7V)

Automatic-Reset Function

The M58479P has a power-supply voltage-detection circuit on-chip, so that the counter is automatically reset by the rising edge of the supply voltage when power is turned on. The reset is then released, making the oscillator ready to function and the counter ready to start counting.

The M58482P can also be provided with the same automatic-reset function by connecting capacitor between terminals $\overline{\text{RESET}}$ and V_{SS} .

Reset Function

When the $\overline{\text{RESET}}$ input turns low (V_{SS}), oscillation of the oscillator can be stopped and the counter reset.

Inhibit Function

When terminal $\overline{\text{INH}}$ turns low (V_{SS}) while the timer is in action, the oscillation halts. When input $\overline{\text{INH}}$ is turned high or returned to OPEN afterwards, it starts to count residual time.

Counter

This counter consists of an 11-stage 1/2 frequency divider, a 2-stage 1/10 frequency divider and a 1-stage 1/6 frequency divider. As shown in the table below, timer duration can be changed by varying the number of pulses counted according to the combination of the input levels on terminals D1 and D2.

D1	D2	Number of pulses counted	Time delay	Typical time delay applied
H	H	1024	T_1	1 min
L	H	1024×10	$T_1 \times 10$	10 min
H	L	$1024 \times 10 \times 6$	$T_1 \times 10 \times 6$	1h
L	L	$1024 \times 10 \times 6 \times 10$	$T_1 \times 10 \times 6 \times 10$	10h

Where, $T_1 = T_0 \times 1024$

T_0 is the value obtained from equation (1)

Output Circuits

The chips have three outputs: OUT1 changes from low to high and OUT2 from high to low as soon as the time duration is up. Either can be used to drive a transistor by connecting it to the transistor base. OUT1 can drive a thyristor when connected to the thyristor gate.

OUT3 is an open-drain output with period 1/8 of the time delay, and can be used to drive a TTL in a separate (5V) power supply line. Thus, if a M53290P counter and a M53242P binary-to-decimal decoder are connected to OUT3, with their output connected to a light-emitting diode, residual time will be displayed on the LED. When not in use, OUT3 should be connected to V_{SS} .

Fine Adjustment of Oscillation Period

A variable resistor can be connected between terminals ADJ and V_{SS} , enabling precise adjustment of the period of the oscillator. However, when not used for fine adjustment, ADJ should be connected to V_{SS} .

APPLICATION EXAMPLE

30-FUNCTION REMOTE-CONTROL TRANSMITTERS

FUNCTIONAL DESCRIPTION

Oscillator

As the oscillator is on chip, oscillation frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Figs. 1 and 2 show typical oscillators.

Fig. 1 An example of an oscillator (using a ceramic resonator)

Fig. 2 An example of an oscillator (using an LC network)

Setting the oscillation frequency to 480 kHz (or 455 kHz) will also set the signal transmission carrier wave to 40 kHz (or 38 kHz).

Power consumption is minimized by stopping oscillation in the oscillator when none of the keys are depressed.

Key Input

Thirty different commands can be input by a 6 x 5 keyboard matrix consisting of inputs I₁ ~ I₆ and scanner outputs φA ~ φE.

In the M58480P, key with first-key entry is given priority, and next-key entry is not allowed unless all keys are released.

In the M58484P, with assigned priority, simultaneous depression of more than two keys makes the key with higher priority effective. Order of key priority for scanner outputs is φA, φB, φC, φD, and φE, and in the same scanner output, I₁, I₂, I₃, I₄, I₅, and I₆.

When more than two keys are depressed at the same time, however, commands may not function due to short-circuiting among scanner outputs.

Table 1 shows the relationship between the keyboard matrix and the transmission commands.

Table 1 Relation between the keyboard matrix and the transmission commands

Scanner output / Key input	φE	φD	φC	φB	φA
I ₁	CH1	CH2	CH3	CH4	POWER ON/OFF
I ₂	CH5	CH6	CH7	CH8	CH UP
I ₃	CH9	CH10	CH11	CH12	CH DOWN

1	1	1	1	1	0	CH 16	

30-FUNCTION REMOTE-CONTROL TRANSMITTERS

Transmission Coding

When oscillation frequency f_{OSC} is 480kHz, transmission of data code is executed as follows: when f_{OSC} is other than 480 kHz, period is multiplied by $480\text{ kHz}/f_{OSC}$ and its frequency by $f_{OSC}/480\text{ kHz}$.

A single pulse is amplitude-modulated by a carrier of 40 kHz, and the pulse width is 0.5ms. Therefore a single pulse consists of 20 clock pulses of 40kHz (see Fig. 3).

The distinction between "0" and "1" bits is made by the pulse interval between pulses, with a 2msec interval corresponding to "0", and a 4msec interval representing "1" (Fig. 4).

One command word is composed of 6 bits, that is, of 7 pulses, and it is transmitted in the 48ms cycle while a matrix switch is depressed.

As mentioned above, adoption of this code means that the period during which output is high (i.e. signal emitting LED is lit) is shorter than in continuous wave transmission. Indeed the LED is on for only half the 7-pulse period or 1.75ms, which is 3.6% of the 48ms entire cycle. This not only saves in total power consumption, but it also improves LED reliability. Put another way, emission can be increased on the same power consumption.

Fig. 3 A single pulse modulated onto carrier (40kHz)

Fig. 4 Distinction between the bits "1" and "0"

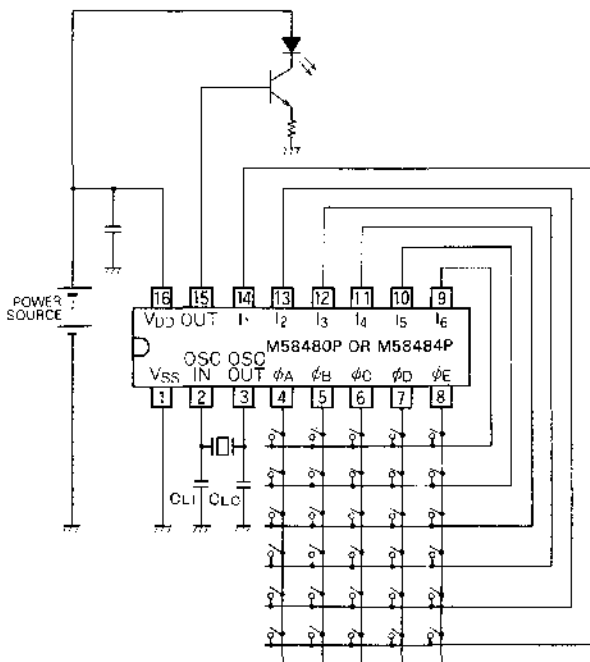

Fig. 5 Synthesis of one word (the code below shows 010100)

30 FUNCTION REMOTE-CONTROL RECEIVER

DESCRIPTION

The M58481P is a 30-function remote-control receiver circuit manufactured by aluminum-gate CMOS technology for use in television receivers, audio equipment, and the like using infrared for transmission. It enables direct control of 16 functions at the receiver.

The M58481P is intended for use with an M58480P or M58484P transmitter.

FEATURES

- Single power supply
- Wide supply voltage range: 4.5V~8V
- Low power dissipation
- On-chip oscillator
- Low-cost LC or ceramic oscillator used in determining reference frequency (480 kHz or 455 kHz)
- Information is transmitted by pulse code modulation
- Good noise immunity—instructions are not executed unless same code is received three or more times in succession
- Single transmission frequency (40 kHz or 38 kHz) for carrier wave
- 16 TV channels selected directly
- Three analog functions—volume, brightness and color saturation—are independently controlled to 64 stages by three 6-bit D/A converters.
- 16 commands are controlled at the M58481P receiver as well
- Has large tolerance in operating frequency between the transmitter and the receiver
- Can be connected with an M51231P or equivalent touch-control channel selector.

APPLICATION

- Remote-control receiver for TV or other applications

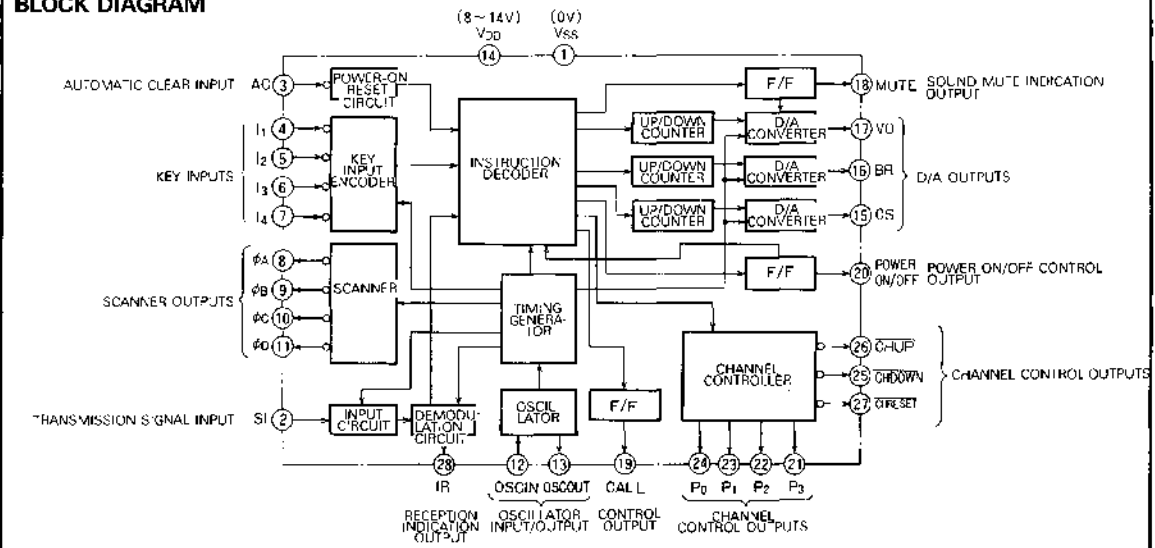

FUNCTION

The M58481P is designed to decode and execute instructions after three successive receptions of the identical instruction code, providing a good noise immunity.

Instructions comprise direct selection of 16 channels, channel position high and low, volume high and low, brightness high and low, color saturation high and low, normalization of volume, brightness and color saturation, sound mute on and off, TV main power on and off, and output CALL on and off.

In addition, 16 functional instructions can be entered from the receiver.

BLOCK DIAGRAM

30-FUNCTION REMOTE-CONTROL RECEIVER

FUNCTIONAL DESCRIPTION

Oscillator

As the oscillator is on-chip, oscillation frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Figs. 1 and 2 show typical oscillators.

Fig. 1 An example of an oscillator (using ceramic resonator)

Fig. 2 An example of an oscillator (using LC network)

Reception Signal Input Circuit and Demodulation Circuit

The reception signal caught by the photo detector is amplified in the amplifier and added to the SI, where it is converted into a pulse signal in the input circuit to be sent to the demodulation circuit. In the demodulation circuit, the pulse interval of the pulse signal is judged and then converted into the digital code to be sent to the instruction decoder.

SI is applied as amplified, either through a capacitor coupling (Fig. 3) or directly as a pulse signal (Figs. 4 and 5). A Schmitt trigger circuit is provided in the SI input circuit for preventing spurious operation due to noise.

Fig. 3 SI input waveform (when applied through a capacitor coupling)

Fig. 4 SI input waveform (when applied directly)

Fig. 5 SI input waveform (when applied directly)

Instruction Decoder

The instruction decoder starts to function after receiving the same instruction code three or more times in succession from the demodulation circuit.

Table 1 shows the relations between the reception code and instruction function. To prevent spurious operation, there is no code 000000.

Table 1 Relations between reception codes and instructions

Reception code						Function	Remarks

1	0	1	1	1	0	CH 14	
0	1	1	1	1	0	CH 15	
1	1	1	1	1	0	CH 16	

Key Inputs

16 different instructions can be input by a 4 x 4 keyboard matrix consisting of inputs I₁~I₆ and scanner outputs φA~φE. Protection is also available against chattering within 10ms.

Entry priority is given to the first key depressed, and subsequent key entry is not allowed unless all keys are released. When two or more keys are depressed at the same time, scanner outputs may short-circuit, disabling all functions.

While one of the keys is depressed, instructions from the transmitter are ignored.

I ₄	CALL	CS DOWN	CS UP	CS(1/2)

Indication of Reception

As soon as an identical code is received three times, output IR turns from low-level to high-level. Thus reception of an instruction from the transmitter can be indicated by an LED connected to output IR. Table 2 shows the relations between the keyboard matrix and the instructions.

Analog Outputs (VO, BR, CS)

As three 6-bit D/A converters are contained internally, three kinds of analog values can be controlled to 64 stages independently. The D/A converters are pulse-width modulator, the repetition frequency is 1.25 kHz (when $f_{osc} = 480$ kHz) and minimum pulse width is 12.5 μ s.

Analog values can be incremented/decremented at a rate of about 1 step/0.1sec through the remote control or key input. The time required for increasing the analog value from the minimum to the maximum is about 6.6 seconds (when $f_{osc} = 480$ kHz).

It is also possible to set the analog values to 1/3 (VO), 1/2 (BR, CS) of these maximum values by means of the remote control or the key input (normalization).

Sound Mute

Sound mute on/off is controlled through the remote control or the key input. When sound mute is on, output VO goes low, and output MUTE goes high.

Sound mute is automatically released from ON when VO is either incremented or decremented by remote control or the key input.

Channel Control

It is possible to employ either of two channel-control methods: parallel control by outputs P₀~P₃, and serial control by outputs CH UP, CH DOWN, and CH RESET.

In parallel control, a 4-bit address corresponding to a selected channel number appears at output P₀~P₃. Table 3 shows the relation between channel numbers and outputs P₀~P₃.

In serial control, a single pulse appears on the output CH RESET first, and then the pulses whose number is deducted by one from the selected channel number appear on the output CH UP, as shown in Fig. 6. Up and down

Fig. 6 Timing chart of serially controlled channel selection (when $f_{osc} = 480$ kHz)

channel switching, is controlled by a single pulse appearing at output CH UP or CH DOWN, allowing connection to the M51231P or equivalent touch-control channel selector IC.

During direct channel selection or up-down channel switching, output VO goes low for 25~50ms.

Table 3 Relations between channel number and address output P₀~P₃.

Channel number	Address outputs			
	P ₀	P ₁	P ₂	P ₃
1	0	0	0	0
2	1	0	0	0
3	0	1	0	0
4	1	1	0	0
5	0	0	1	0
6	1	0	1	0
7	0	1	1	0
8	1	1	1	0
9	0	0	0	1
10	1	0	0	1
11	0	1	0	1
12	1	1	0	1
13	0	0	1	1
14	1	0	1	1
15	0	1	1	1
16	1	1	1	1

Power On/Off

The remote control or the key input makes it possible to turn the POWER ON/OFF output from low to high or vice versa, effecting on/off control of the TV set.

While POWER ON/OFF is low, all channel and analog controls through the remote control are disabled, as are all through the keyboard, except CH RESET ($\phi_D \sim I_1$), VO (1/3), BR (1/2), and CS (1/2) ($\phi_D \sim I_3$).

Output CALL

The output CALL is turned high or low by remote control or the key input. This output effects on/off control of channel number indication or change of receiving modes of multi-channel broadcasting.

Power-on Reset

Attaching a capacitor to terminal AC activates the power-on reset function when power is on to the M58481P.

Activation of the power-on reset function sets outputs VO, BR, and CS to 1/3, 1/2, and 1/2, respectively, of their maximum value, turns POWER ON/OFF and CALL outputs low, and turns outputs P₀~P₃ to 0000.

APPLICATION EXAMPLE

29-FUNCTION REMOTE-CONTROL RECEIVER

DESCRIPTION

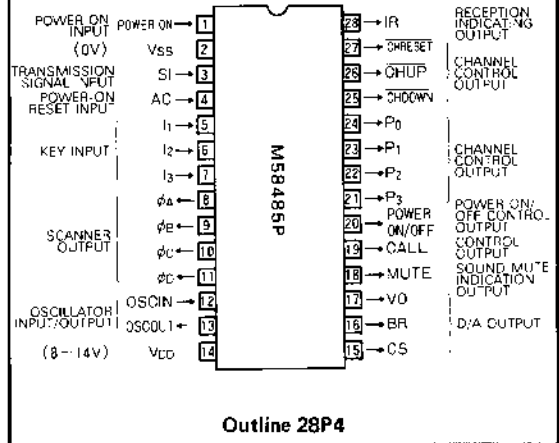

The M58485P is a 29-function remote-control receiver circuit manufactured by aluminum-gate CMOS technology for use in television receivers, audio equipment, and the like using infrared for transmission. It enables direct control of 12 functions at the receiver.

The M58485P is intended for use with an M58480P or M58484P transmitter.

FEATURES

- Single power supply
- Wide supply voltage range: 8V~14V
- Low power dissipation
- On-chip oscillator
- Low-cost LC or ceramic oscillator used in determining reference frequency (480 kHz or 455 kHz)
- Information is transmitted by pulse code modulation
- Good noise immunity—instructions are not executed unless the same code is received three or more times in succession
- Single transmission frequency (40 kHz or 38 kHz) for carrier wave
- 16 TV channels selected directly
- Three analog functions— volume, brightness, and color saturation—are independently controlled to 64 stages by three 6-bit D/A converters
- 12 instructions are controlled at the M58485P receiver, as well.
- Has large tolerance in operating frequency between the transmitter and the receiver
- Can be connected with an M51231P or equivalent touch-control channel selector

PIN CONFIGURATION (TOP VIEW)

APPLICATION

- Remote-control receiver for TV or other applications

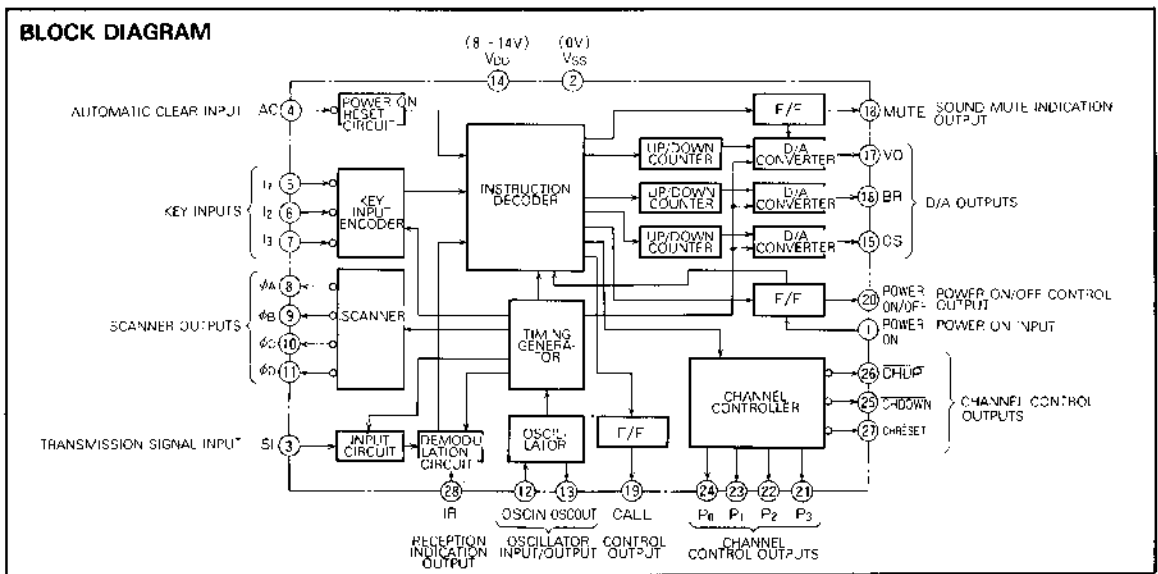

FUNCTION

The M58485P is designed to decode and execute instructions after three successive receptions of the identical instruction code, providing a good noise immunity.

Instructions comprise direction selection of 16 channels, channel position high and low, volume high and low, brightness high and low, color saturation high and low, normalization of volume, brightness and color saturation, sound mute on and off, TV main power on and off, and output CALL on and off.

In addition, 12 functional instructions can be entered from the receiver.

BLOCK DIAGRAM

29-FUNCTION REMOTE-CONTROL RECEIVER

FUNCTIONAL DESCRIPTION

Oscillator

As the oscillator is on-chip, oscillation frequency is easily obtained by connecting an external LC network or a ceramic resonator between the OSC IN and OSC OUT terminals. Figs. 1 and 2 show typical oscillators.

Fig. 1 An example of an oscillator (using ceramic resonator)

Fig. 2 An example of an oscillator (using LC network)

Reception Signal Input Circuit and Demodulation Circuit

The reception signal caught by the photo detector is amplified in the amplifier and added to the SI, where it is converted into a pulse signal in the input circuit to be sent to the demodulation circuit. In the demodulation circuit, the pulse interval of the pulse signal is judged and then converted into the digital code to be sent to the instruction decoder.

SI is applied as amplified either through a capacitor coupling (Fig. 3) or directly as a pulse signal (Figs. 4 and 5). A Schmitt trigger circuit is provided in the SI input circuit for preventing spurious operation due to noise.

Fig. 3 SI input waveform (when applied through a capacitor coupling)

Fig. 4 SI input waveform (when applied directly)

Fig. 5 SI input waveform (when applied directly)

Instruction Decoder

The instruction decoder starts to function after receiving the same instruction code three or more times in succession from the demodulation circuit.

Table 1 shows the relations between the reception code and instruction function. To prevent spurious operation, there is no code 000000.

Table 1 Relations between reception codes and instructions

Reception code						Function	Remarks

Key Inputs

It is possible to input 12 different instructions by the 3 x 4 keyboard matrix consisting of inputs I₀~I₃ and scanner outputs φA~φD. Protection is also available against chattering within 10ms.

As entry priority is given to each key, depression of more than two keys at the same time makes the key with higher priority effective. For the scanner output, priority is given in the order of φA, φB, φC, and φD, and in the order of I₁, I₂, and I₃ if scanner output is the same. When two or more keys are depressed at the same time, scanner outputs may short-circuit, disabling all functions.

While one of the keys is depressed, instructions from the transmitter are ignored.

Table 2 shows the relations between the keyboard matrix and the commands.

29-FUNCTION REMOTE-CONTROL RECEIVER

Table 2 Relations between keyboard matrix and instructions

Scanner output Key input	ϕD	ϕC	ϕB	ϕA
I ₁	CH UP	VO UP	BR UP	CS UP
I ₂	CH DOWN	VO DOWN	BR DOWN	CS DOWN
I ₃	POWER ON/OFF	MUTE	VO (1/3) BR (1/2) CS (1/2)	CALL

Indication of Reception

As soon as an identical code is received three times, the output IR turns from low-level to high-level. Thus reception of a command from the transmitter can be indicated by an LED connected to output IR.

Analog Outputs (CO, BR, CS)

As three 6-bit D/A converters are contained internally, three kinds of analog values can be controlled to 64 stages independently. The D/A converters are pulse-width modulator, and the repetition frequency is 1.25 kHz (when $f_{OSC} = 480$ kHz) and minimum pulse width is 12.5 μ s.

Analog values can be incremented/decremented at a rate of about 1 step/0.1 sec through the remote control or the key input. The time required for increasing the analog value from the minimum to the maximum is about 6.6 seconds (when $f_{OSC} = 480$ kHz).

It is also possible to set the analog values to 1/3 (VO), 1/2 (BR, CS) of these maximum values by means of the remote control or the key input (normalization).

Sound Mute

Sound mute on/off is controlled through the remote control or the key input. When sound mute is on, output VO goes low, and output MUTE goes high.

Sound mute is automatically released from ON when VO is either incremented or decremented by remote control or the key input.

Channel Control

It is possible to employ either of two channel control methods: parallel control by outputs P₀~P₃, and serial control by outputs CH UP, CH DOWN, and CH RESET.

In parallel control, a 4-bit address corresponding to a selected channel number appears at output P₀~P₃. Table 3 shows the relations between channel numbers and outputs P₀~P₃.

In serial control, a single pulse appears on the output CH RESET first, and then the pulses whose number is deducted by one from the selected channel number appear on the output CH UP, as shown in Fig. 6. Up and down channel switching is controlled by a single pulse appearing at output CH UP or CH DOWN, allowing connection to the M51231P or equivalent touch-control channel selector IC.

Table 3 Relations between channel number and address output P₀~P₃.

Channel number	Address outputs			
	P ₀	P ₁	P ₂	P ₃
1	0	0	0	0
2	1	0	0	0
3	0	1	0	0
4	1	1	0	0
5	0	0	1	0
6	1	0	1	0
7	0	1	1	0
8	1	1	1	1
9	0	0	0	1
10	1	0	0	1
11	0	1	0	1
12	1	1	0	1
13	0	0	1	1
14	1	0	1	1
15	0	1	1	1
16	1	1	1	1

Fig. 6 Timing chart of serially controlled channel selection (when $f_{osc} = 480$ kHz)

During direct channel selection or up-down channel switching, output VO goes low for 25~50ms.

Outputs, CH UP, CH DOWN, CH RESET, and P₀~P₃, are the open-drain type of N-channel transistor.

Power on/off

The remote control or the key input makes it possible to turn the POWER ON/OFF output from low to high or vice versa, and it is possible to change the POWER ON/OFF output from low to high by means of the POWER ON input.

While POWER ON/OFF is low, all channel and analog controls through the remote control are disabled, as are all through the keyboard.

Output CALL

The output CALL is turned high or low by remote control or the key input. This output effects on/off control of channel number indication or change of receiving modes of multi-channel broadcasting.

Power-on Reset

Attaching a capacitor to terminal AC activates the power-on reset function when power is on to the M58485P.

Activation of the power-on reset function sets outputs VO, BR, and CS to 1/3, 1/2, and 1/2, respectively, of their maximum value, turns POWER ON/OFF and CALL outputs low and turns outputs P₀~P₃ to 0000.

APPLICATION EXAMPLE

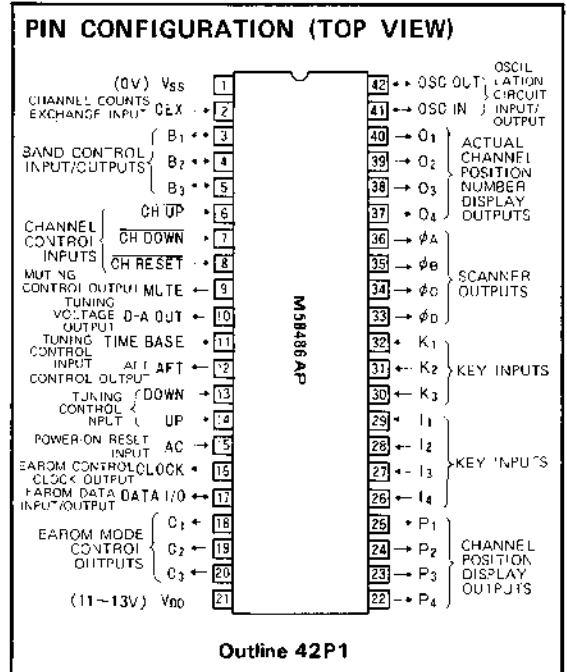

VOLTAGE SYNTHESIZER

DESCRIPTION

The M58486AP is an aluminum gate CMOS integrated circuit. It has a fully automatic search function capable of writing into an EAROM the tuning voltages corresponding to all receivable stations and a sequentially automatic search function which presets any arbitrary channel. Used in conjunction with the M51251P linear sensor and M5G1400P EAROM, it is possible to configure a fully electronic tuning system for use in TVs or VTR equipment.

FEATURES

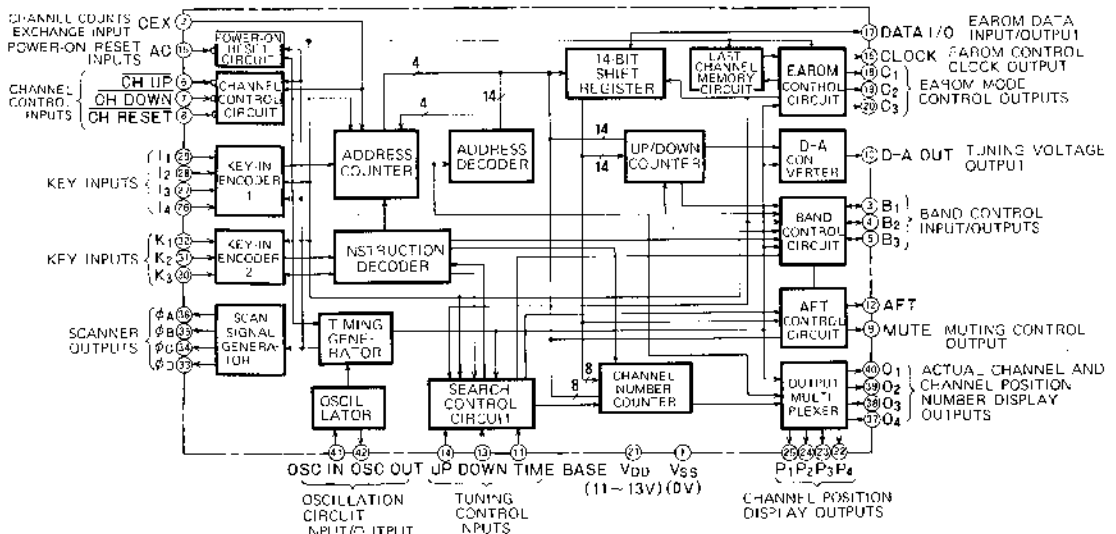

- Fully automatic search and sequentially automatic search functions
- The channel display provides channel position tab display, channel position number display, and actual channel number display
- Automatic bandswitching
- Band skip function
- Digital AFT (Automatic Fine Tuning) function
- Frequency fine adjustment function
- AFT on/off data is memorized in EAROM for each channel position
- Direct connection with a remote controller LSI such as the M58485P or M58487AP
- Direct 16 (or 12) channel selection
- Last channel memory function

APPLICATIONS

Electronic tuning systems for TVs, VTRs, and other electronic equipment.

BLOCK DIAGRAM

VOLTAGE SYNTHESIZER

FUNCTION

The M58486AP voltage synthesizer, when used in conjunction with the M51251P linear sensor and M5G1400P EAROM, enables the configuration of a completely electronic tuning system without the use of any mechanical parts.

The main functions include fully automatic search, sequentially automatic search, direct selection of either 12 or 16 channels, automatic bandswitching, a band skip function, digital AFT (Automatic Fine Tuning), fine tuning, last channel memory, channel position tab display, channel position number display, and actual channel number display functions.

In addition, direct and sequential channel selection from a remote controller as possible.

FUNCTIONAL DESCRIPTION

Oscillator Circuit

As the oscillator is on-chip, an oscillator frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Fig. 1 and 2 show typical examples.

Fig. 1 An example of an oscillator (using a ceramic resonator)

Fig. 2 An example of an oscillator (using an LC network)

Key Inputs

The M58486AP is provided with scanner outputs $\phi_A \sim \phi_D$, key inputs $I_1 \sim I_4$ and $K_1 \sim K_3$. 16-channel position selection can be achieved by using the 4x4 matrix formed by $\phi_A \sim \phi_D$ and $I_1 \sim I_4$. In addition, the 4x3 matrix formed by $\phi_A \sim \phi_D$ and $K_1 \sim K_3$ enables the input of 12 commands.

If two or more of the keys are depressed simultaneously,

no commands will be input. However, it is possible to input FAM or CH LOCK in combination with another key.

Table 1 shows the relationships between these matrices and the command functions.

Table 1 Matrix and Command Functions

$I \backslash \phi$	ϕ_A	ϕ_B	ϕ_C	ϕ_D
I_1	CHP 1	CHP 5	CHP 9	CHP 13
I_2	CHP 2	CHP 6	CHP 10	CHP 14
I_3	CHP 3	CHP 7	CHP 11	CHP 15
I_4	CHP 4	CHP 8	CHP 12	CHP 16

$K \backslash \phi$	ϕ_A	ϕ_B	ϕ_C	ϕ_D
K_1	U-SEARCH	D/A UP	CHN 10	CHP-UP
K_2	V-SEARCH	D/A DOWN	CHN 1	CHP-DOWN
K_3	SEARCH	CH LOCK	FAM	STORE

Tuning Voltage Output (D/A OUT)

As a 14-bit D-A converter is built into the M58486AP, tuning voltage can be controlled to 16384 stages. The D-A converter is a pulse-width modulator, and the repetition frequency is 28Hz and the minimum pulse width is 2.2 μ s.

By applying this output signal to the electronic tuner through an RC network, the desired tuning frequency can be achieved.

Tuning Control Inputs (UP, DOWN, TIME BASE)

These inputs are required for tuning in the search mode or channel selection mode and are supplied by the M51251P.

As shown in Fig. 3, UP and DOWN inputs are controlled by the AFC signal. The UP input is changed to a high level when the AFC signal exceeds a threshold voltage (V_H) and the DOWN input is changed to a high level when the AFC signal falls below a threshold voltage (V_L).

The TIME BASE input is high when a normal video signal is captured.

Fig. 3 Relationship of AFC signal to UP and DOWN inputs

VOLTAGE SYNTHESIZER

Band Input/Outputs (B1 ~ B3)

The M58486AP system is provided with three bands. An electronic tuner is controlled by these three band inputs/outputs and D-A OUT.

As shown in Table 2, these bands correspond to the TV broadcast frequency bands.

Band	Broadcast frequency band
B1	VHF low band
B2	VHF high band
B3	UHF

Three band inputs (B1 ~ B3) are provided on the M58486AP, the output corresponding to the currently selected band being high, with all other band outputs low. Thus, by connecting transistor and LED with currents to these outputs a display of the selected band can be implemented.

If a particular band pin is shorted to V_{SS} that band will be skipped during the search (band skip function).

Search Modes

The search is the function searching automatically the video signal and writing of the required data into the EAROM.

The search function is controlled by the UP, DOWN, and TIME BASE tuning control inputs. Search functions will be described using Fig. 3, 4, and 5.

When search is begun, as up signal is applied to the 14-bit up/down counter, and the analog output of the D-A converter increases (sweeps).

As shown in Fig. 3 and 4, when the signal reaches a certain point, the UP input changes to high. Next, if the DOWN input goes high within 50ms after the UP input goes low, the sweep is ended and the digital AFT is enabled. If DOWN doesn't go high within 50ms, this is taken as an indication that the signal was not a video signal, and the sweep is continued.

Digital AFT is controlled by both the UP and DOWN inputs. When UP is high, the up signal is applied to the up/down counter and the analog output of the D-A converter increases. When DOWN is high, the down signal is applied to the up/down counter and the analog output of the D-A converter decreases. The up/down speed of digital AFT is 1/16 of the up sweep speed.

Digital AFT is ended after 200ms, after which the TIME BASE input is examined. If TIME BASE is low, it is taken as an indication that the signal is not a video signal and the sweep operation is restarted. If TIME BASE is high, the signal is taken as a video signal and the required data is written into the EAROM at the specified address. For this operation, the EAROM address is determined by the channel position and the data written is as follows.

Note, however, that for automatic writing of data into EAROM in the search mode, AFT data is on.

14-bit up/down counter data	14 bits
2-digit BCD data of channel number counter	8 bits
Band control binary data	2 bits
AFT on/off control data	1 bit

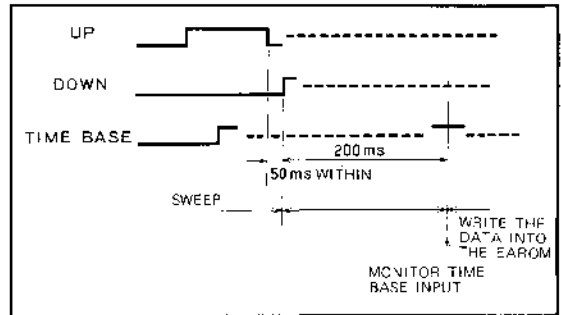

Fig. 4 UP, DOWN, TIME BASE inputs in the search mode

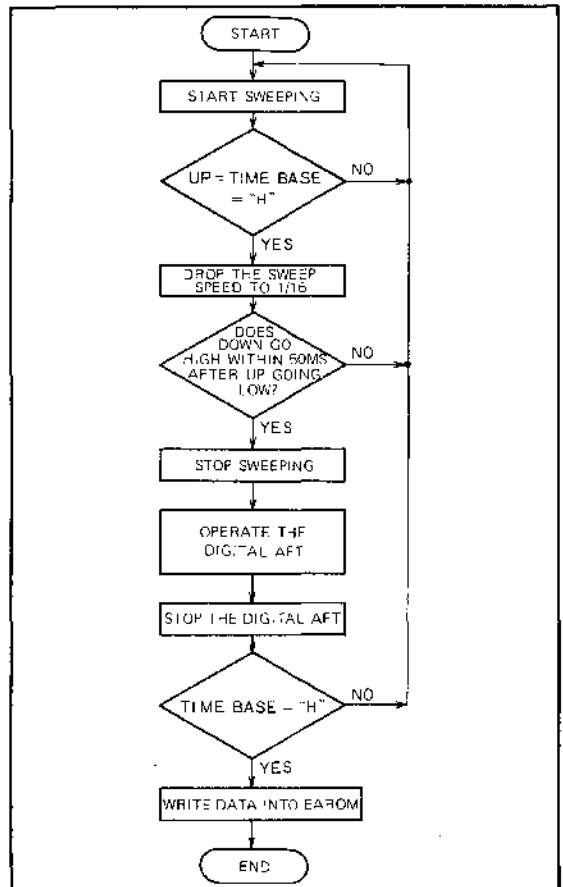

Fig. 5 A flowchart of the search method

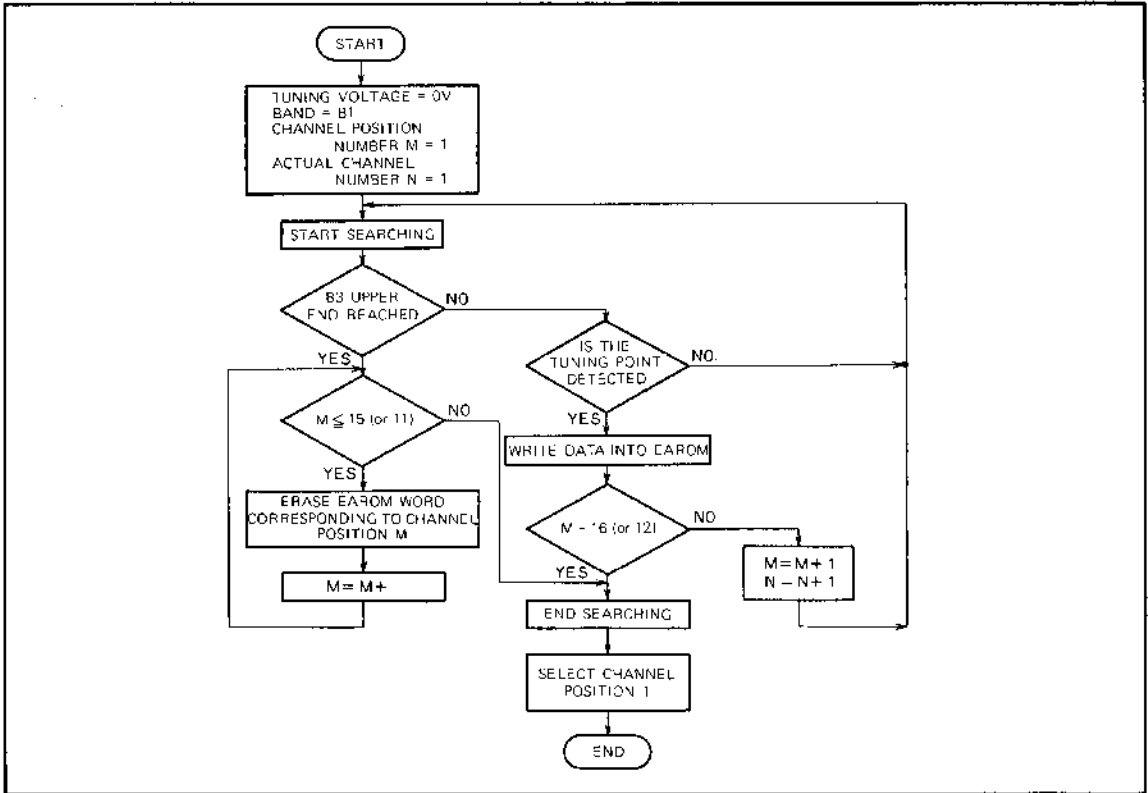

Fig. 6 A flowchart of fully automatic search (SEARCH or V-SEARCH)

Fully Automatic Search

Fig. 6 shows the flowchart of the fully automatic search.

When SEARCH or V-SEARCH key is input, the D-A converter analog output is set to the lower end of B1 and the channel position number and actual channel number are both initialized to 1.

After initialization, search begins and when a video signal is captured, the required data is automatically written into the EAROM, the channel position number and actual channel number being incremented by 1, after which the search is restarted.

In this manner, when tuning voltage goes to the upper end of band B3 or when all 16 (or 12) channel positions are written, the EAROM data corresponding to channel position number 1 (channel position 1 is selected) is read, and the fully automatic search operation is completed. If the upper end of band B3 is reached before all 16 (or 12) channels have been searched, the data at the EAROM addresses corresponding to reset channel position is erased. If these erased channel positions are selected, the D-A converter analog output is set to the lower end of band B1, the actual channel number is set to 0, and the AFT function is turned off.

When U-SEARCH key is input, the operation is exactly the same as the above described SEARCH or V-SEARCH except that initialization to the lower end of band B3 is performed and the search ends at the upper edge band B2.

Also, during fully automatic search, no key command can be input.

Sequentially Automatic Search

For sequentially automatic search, the channel position and actual channel number are the currently selected channel position.

When V-SEARCH key is input, search begins from the current position if the current band is B1 or B2, and from the lower end of band B1 if the current band is B3.

The search begins and when a video signal has been captured, the required data is automatically written into the EAROM, the search mode is cancelled, and the search is completed. When the upper end of the B2 band is reached, the tuning voltage output returns to the lower end of the B1 band and search continues.

When U-SEARCH key is input, search begins at the present location if the current band is B3. If it is B1 or B2, it begins at the lower end of band B3. The search method is exactly the same as for the above described V-SEARCH

VOLTAGE SYNTHESIZER

except that when the upper end of band B3 is reached, the tuning voltage returns to the lower end of band B3.

When SEARCH key is input, search begins from the current location. For SEARCH, when the upper end of band B3 is reached, the tuning voltage returns to the lower end of band B1.

During sequentially automatic search, pressing channel selector keys cancels the search mode, ending the search and resulting in input of the channel selection command.

Search Speed

The tuning voltage rate of change varies between bands and within bands such that the search speed with respect to frequency is virtually constant over the entire range.

Because of the time constant associated with the integration circuit connected to the D/A OUT output, time delays occurs during the sweep. However, to compensate for this when UP and TIME BASE inputs are both high, the search speed is dropped to 1/16 of the sweep speed.

Table 3 shows the search speed for all bands without this reduced speed mode.

Table 3 Search Speed for Each Band

Band Tuning voltage	B1	B2	B3, B4
0 ~ 1/4	1.16s	2.31s	9.22s
1/4 ~ 1/2	0.58	1.16	
1/2 ~ 1	0.58	1.16	4.61
Total	2.32	4.63	13.83

Note 1. The reference oscillator frequency is 455kHz.
 2. The tuning voltage is given normalized to a value of 1

Switching between fully automatic search and sequentially automatic search is accomplished by the FAM command as shown in Table 1. By using a switch, connecting the ϕ_C pin, with the K_3 pin results in fully automatic search while opening this connection results in switching to sequentially automatic search.

If the FAM command is attempted during a search, the command will not immediately be executed. After the search mode has been cancelled it will be input and the appropriate search mode, either fully automatic or automatic sequential search, will be selected.

VOLTAGE SYNTHESIZER

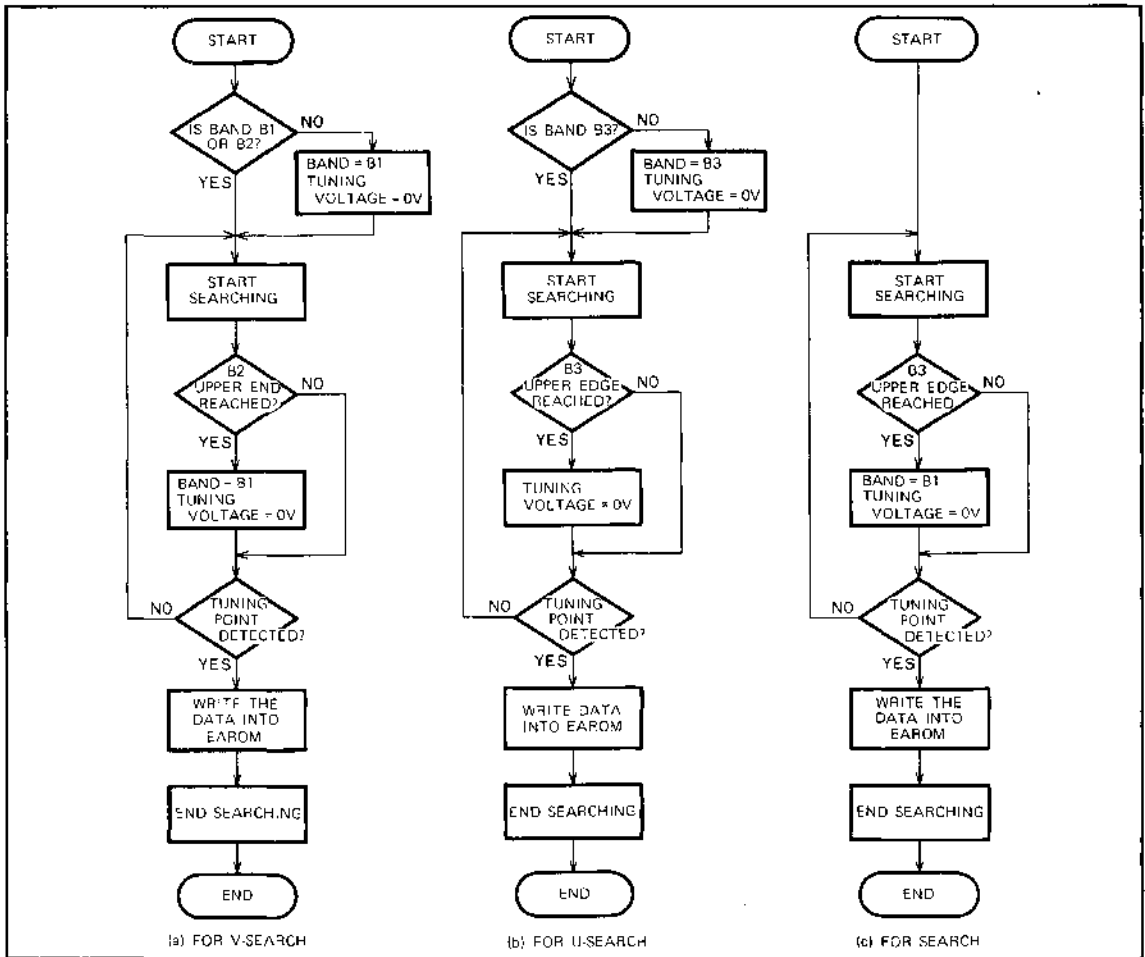

Fig. 7 Shows the flowchart of sequentially of search.

Channel Selection Mode

When either a channel selection key is depressed or a channel selection command is input from a remote control receiver (described below), the data at the EAROM address corresponding to the selected channel position is read.

After the read data is set in the up/down counter, if the AFT control data read is on, 16 down pulses are applied, causing the up/down counter to count down and cause a corresponding output from the D-A converter. This is to enable pull-in at the optimum position of the video signal, using the digital AFT and linear AFT to be described next.

If the AFT control data read is on, after 100 ms digital AFT is enabled. In addition, when 100ms has elapsed, the AFT output goes high and linear AFT is enabled. When the AFT control data is off, both digital and linear AFT functions are disabled.

Tuning Voltage Fine Adjustment (D-A UP, D-A DOWN)

By pressing the D-A UP and D-A DOWN key, it is possible to adjust the D-A converter analog output (that is the tuning voltage).

After channel selection, pressing the D-A UP or D-A DOWN keys turns AFT off and disables both digital and linear AFT functions. After this, the up or down signals are applied to the up/down counter and the D-A converter analog output changes. The rate of this change is 1/128 of the sweep speed, allowing sufficient fine adjustment.

When the key is released writing into the EAROM begins. At this time, the AFT on/off data is written as off.

VOLTAGE SYNTHESIZER

EAROM Input/Output (CLOCK, C₁, C₂, C₃, DATA I/O)
This system makes use of an M5G1400P as an EAROM.

To control the M5G1400P, the M58486AP is provided with a reference clock (~14kHz) output clock, outputs C₁, C₂, and C₃ used to specify the mode, and a data input/output DATA I/O.

These inputs and outputs are controlled by the EAROM control circuit. The clock output is fixed at the V_{DD} level at all times except during memory read and write operations.

AFT Output

The AFT pin is connected to the AFT on/off pin (pin 15) of the M51251P, and is used to on/off control linear AFT. When the AFT output is high, linear AFT is enabled. When it is low or high impedance (open) linear AFT is disabled. Table 4 summarizes the AFT output for the various states.

Table 4 AFT Outputs for the Various Modes

Mode	AFT output level
Search mode (during sweep)	L
Search mode (during the 200ms that digital AFT is enabled)	Z
Channel selection mode (with linear AFT on)	H
Channel selection mode (with linear AFT off)	Z

Note 1. 'Z' indicates high-impedance (open)

Last Channel Memory

In this system when the power supply is applied, a last channel memory function selects the last channel position that was selected before the power supply was last removed.

This function is controlled by the last channel memory circuit such that when a channel is selected the data for the selected channel position is written into a specified address in the EAROM. Each time a channel is selected the data contents are updated so that the last channel selected before power is removed is always stored. When the power is applied, this data is read from the EAROM and used as the initial channel position selected.

Channel Position Display (P₁ ~ P₄)

By connecting transistors and LEDs to the 4x4 matrix formed by the P₁ ~ P₄ and φ_A ~ φ_D outputs, a 16-channel position display can be configured.

The display repetition frequency is 45Hz and the duty cycle is 23.5%. Fig. 8 gives an example of output timings. Note that when not used pins should be connected to V_{DD}.

Channel Number Display (O₁ ~ O₂)

The output O₁ ~ O₄ provide a two-digit (0 ~ 99) BCD output of the actual channel number. The upper and lower digits are output under the control of the φ_D and φ_B scan signals. Thus, by using a BCD seven-segment decoder (for example, the M53247P or equivalent), it is possible to

display the actual channel number using a two-digit seven-segment display. Fig. 9 shows an example of timing for the outputs O₁ ~ O₄ used to display the actual channel number.

Fig. 8 Timing example for outputs P₁~P₄ and φ_A~φ_D (channel position = 7)

When the O₁ ~ O₄ outputs are used to display the channel position number in binary form the φ_A and φ_C scan signals are used for timing of the outputs. For the channel positions 1 ~ 16, the O₁ ~ O₄ outputs are 0 ~ 15. Therefore, the channel position number can be displayed using seven-segment display elements. Fig. 9 shows a timing example of the outputs O₁ ~ O₄ used to display the channel position number. The outputs O₁ through O₄ use N-channel transistors in open drain configuration. When not used they should be connected to the V_{SS} pin.

Fig. 9 Timing example for outputs O₁~O₄ and φ_A~φ_D (Actual channel number setting line 79 Channel position number 7)

VOLTAGE SYNTHESIZER

Actual Channel Number Control Inputs (CHN 10, CHN 1)

When CHN 10 key is input, the upper digit of the actual channel number is incremented by 1, cycling back to 0 after reaching 9. In the same manner, when CHN 1 key is input, the lower digit is incremented by 1. Therefore, by using these inputs, the actual channel number can be changed with respect to the channel position, and by using the STORE command described below, the proper corresponding channel numbers can be selected.

Channel Position Control Inputs (CHP-UP, CHP-DOWN)

When either CHP-UP or CHP-DOWN key is input, the contents of the address counter are incremented or decremented by 1, the channel position display changing accordingly. But data is not read from the EAROM, so the D-A converted analog output, band, AFT output and actual channel do not change.

When these commands are input, the channel position is changed, and the STORE command described below is input, data is written into the EAROM at the address corresponding to the displayed channel position. This enables, for example, such copying operations as writing the same data in position 3 as stored in position 1.

EAROM Write Command (STORE)

When the STORE command is input, data is written into the EAROM at the address corresponding to the currently displayed channel position. This STORE command is used to change the actual channel number and to perform memory copying operations.

Audio Control Output (MUTE)

In the search mode or channel selection mode, the MUTE output changes to a high level, enabling the muting function which lowers the sound level to the minimum level. This output is normally low.

Power-on reset (\overline{AC})

By connecting a capacitor between the \overline{AC} pin and the V_{SS} pin, the power-on reset function is enabled upon applying power to the M58486AP.

When the power-on reset operates, the last channel memory function is enable the channel position selected before the power was removed, is selected.

Remote Control Inputs ($\overline{CH UP}$, $\overline{CH DOWN}$, $\overline{CH RESET}$)

If the $\overline{CH UP}$, $\overline{CH DOWN}$, and $\overline{CH RESET}$ inputs are connected to the corresponding pins on, for example, a remote control receiver device such as the M58485P or M58487AP, direct remote control of channel selection, channel up, and channel down functions is possible.

Channel Lock Input (CH LOCK)

By using the input combination of the key input K_3 and the scan signal ϕ_B , the CH LOCK command is input. This command prohibits the CHP1 ~ CHP16, CHP-UP, AND CHP-DOWN keys commands as well as the remote control $\overline{CH-UP}$, $\overline{CH-DOWN}$, and $\overline{CH-RESET}$. This command is independent of any other key commands and can be input simultaneously input with any command except the channel selection commands CHP1~CHP16.

Number of Channels Selection Input (CEX)

The CEX input is provided with a built-in pull-up resistance and when at the high level (or open), the M58486AP for 16 channels. When it is at the low level the M58486AP accommodates 12 channels.

VOLTAGE SYNTHESIZER

APPLICATION EXAMPLE

24-FUNCTION REMOTE-CONTROL RECEIVER

DESCRIPTION

The M58487AP is a 24-function remote-control receiver circuit manufactured by aluminum-gate CMOS technology for use in television receivers, audio equipment, and the like, using infrared for transmission. It enables direct control of 8 functions at the receiver.

The M58487AP is intended for use with an M58480P or M58484P transmitter.

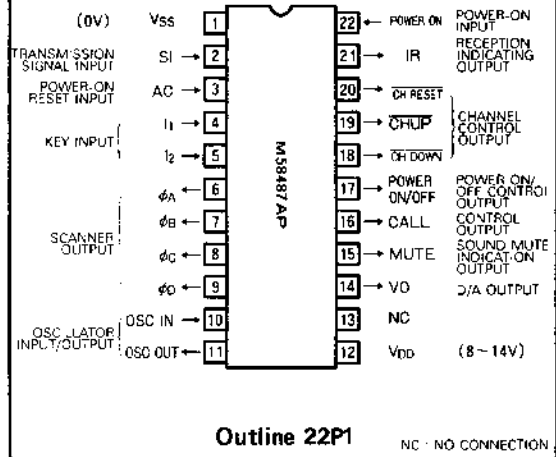

FEATURES

- Wide supply voltage range: 8V~14V
- Single power supply
- Low power dissipation
- On-chip oscillator
- Low-cost LC or ceramic oscillator used in determining the reference frequency (480kHz or 455kHz)
- Information is transmitted by means of pulse code modulation
- Good noise immunity—instructions are not executed unless same code is received three or more times in succession.
- Single transmission frequency (40kHz or 38kHz) for carrier wave
- 16 TV channels selected directly
- Three analog functions—volume, brightness, and color saturation—are independently controlled to 64 stages by three 6-bit D/A converters
- 8 commands are controlled at the M58487AP receiver
- Has large tolerance in operating frequency between the transmitter and the receiver.
- Can be connected with an M51231P or equivalent touch control channel selector IC

APPLICATION

- Remote-control receiver for TV or other applications

PIN CONFIGURATION (TOP VIEW)

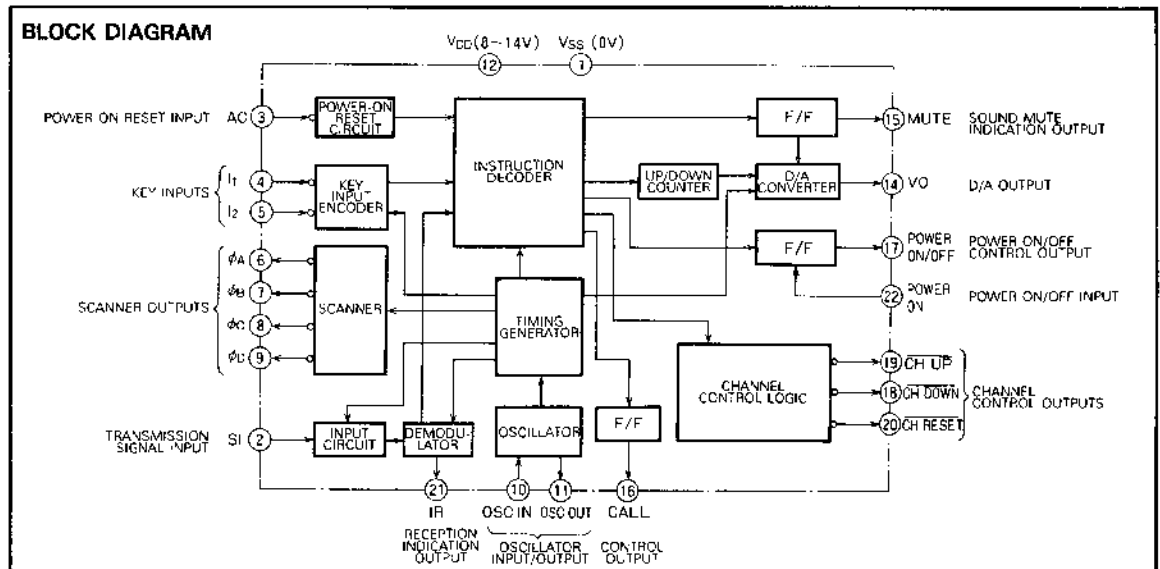

FUNCTION

The M58487AP is designed to decode and execute instructions after three successive receptions of the identical instruction code, providing a good noise immunity.

Instructions comprise direct selection of 16 channels, channel position up and down, volume up and down, brightness up and down, color saturation up and down, normalization of volume, brightness and color saturation, sound mute on and off, TV main power on and off, and output CALL on and off.

In addition, 8 functional instructions can be entered from the receiver side.

BLOCK DIAGRAM

24-FUNCTION REMOTE-CONTROL RECEIVER

FUNCTIONAL DESCRIPTION
Oscillator

As the oscillator is on-chip, oscillation frequency is easily obtained by connecting an external LC network or ceramic resonator between the OSC IN and OSC OUT terminals. Figs. 1 and 2 show typical oscillators.

Fig. 1 An example of an oscillator (when a ceramic resonator is used)

Fig. 2 An example of an oscillator (when a LC network is used)

Reception Signal Input Circuit and Demodulation Circuit

The reception signal caught by the photo detector is amplified in the amplifier and added to the SI, where it is converted into a pulse signal in the input circuit to be sent to the demodulation circuit. In the demodulation circuit, the pulse interval of the pulse signal is judged and then converted into the digital code to be sent to the instruction decoder.

SI is applied as amplified, either through a capacitor coupling (Fig. 3) or directly as a pulse signal (Figs. 4 and 5). A Schmitt trigger circuit is provided in the SI input circuit for preventing spurious operation due to noise.

Fig. 3 SI input waveform (when applied through a capacitor coupling)

Fig. 4 SI input waveform (when applied directly)

Fig. 5 SI input waveform (when applied directly)

Instruction Decoder

The instruction decoder starts to function after receiving the same instruction code three or more times in succession from the demodulation circuit.

Table 1 shows the relations between the reception code and instruction function. To prevent spurious operation, there is no code 000000.

Table 1 Relations between reception codes and instructions

Reception code						Function	Remarks
D ₁	D ₂	D ₃	D ₄	D ₅	D ₆		
1	0	0	0	0	0	CH UP	Channel up
0	1	0	0	0	0	CH DOWN	Channel down

0	0	1	1	1	0	CH 13	
1	0	1	1	1	0	CH 14	
0	1	1	1	1	0	CH 15	
1	1	1	1	1	0	CH 16	

Key Inputs

8 different instructions are input by a 2 x 4 keyboard matrix consisting of inputs I₁ ~ I₂ and scanner outputs φA ~ φD. Protection is also available against chattering within 10ms.

As entry priority is given to each key, depression of more than two keys at the same time makes the key with higher priority effective. For the scanner output, priority is given in the order of φA, φB, φC, and φD, and I₁ takes precedence over I₂ if the scan output is the same. When two or more keys are depressed at the same time, scanner outputs may short-circuit, disabling all functions.

While one of the keys is depressed, instructions from the transmitter are ignored.

Table 2 shows the relations between the keyboard matrix and the instructions.

Table 2 Relations between keyboard matrix and instructions

Key input	Scanner output	φD	φC	φB	φA
I ₁	POWER ON/OFF	VO UP	MUTE	CH UP	
I ₂	CALL	VO DOWN	VO(1/3)	CH DOWN	

24-FUNCTION REMOTE-CONTROL RECEIVER

Indication of Reception

As soon as an identical code is received three times, output IR turns from low-level to high-level. Thus reception of an instruction from the transmitter can be indicated by an LED connected to the output IR.

Output VO

As the 6-bit D/A converter is contained internally, analog value can be controlled to 64 stages independently. The D/A converter is pulse-width modulator, the reception frequency is 1.25kHz (when $f_{OSC} = 480kHz$) and minimum pulse width is 12.5 μs .

Analog value can be incremented/decremented at a rate of about 1 step/0.1 second through the remote control or the key input. The time required for increasing the analog value from the minimum to the maximum is about 6.6 seconds (when $f_{OSC} = 480kHz$).

It is also possible to set the analog value to 1/3 of its maximum value by means of the remote control or the key input (normalization).

Sound Mute

Sound mute on/off is controlled through the remote control or the key input. When sound mute is on, output VO goes low, and output MUTE goes high.

Sound mute is automatically released from ON when the output VO is either incremented or decremented by remote control or the key input.

Channel Control

Channel control is attained through outputs $\overline{CH\ UP}$, $\overline{CH\ DOWN}$ and $\overline{CH\ RESET}$. With respect to direct channel selection by the remote-control operation, a single pulse appears on output $\overline{CH\ RESET}$ first, and then the pulses whose number is deducted by one from the selected channel appear on the output $\overline{CH\ UP}$. Up and down channel switching is controlled by presenting a single pulse on the output $\overline{CH\ UP}$ or $\overline{CH\ DOWN}$. Thus it can be connected with an M51231P or equivalent touch-control channel selector IC.

Fig. 6 Timing chart of channel control (when $f_{osc} = 480kHz$)

During direct channel selection, up or down, output VO goes low for 50~100ms.

Outputs, $\overline{CH\ UP}$, $\overline{CH\ DOWN}$, and $\overline{CH\ RESET}$ are the open-drain type of N-channel transistor.

Power On/Off

The remote control or the key input makes it possible to turn the POWER ON/OFF output from low to high or vice versa. While the POWER ON/OFF output is low, all channel and analog controls through the remote control are disabled, as are all through the keyboard.

Output CALL

The output CALL is turned high or low by remote control or the key input. This output effects on/off control of channel number indication or change of receiving modes of multi-channel broadcasting.

Power-on Reset

Attaching a capacitor to terminal AC activates the power-on reset when power is on to the M58487AP.

Activation of the power-on reset function sets output VO to 1/3 of its maximum value and turns the POWER ON/OFF and CALL outputs to low-level.

APPLICATION EXAMPLE

MICROCOMPUTER SYSTEMS

MITSUBISHI MICROCOMPUTERS PCA8501G01, G02

MELCS 85/2 SINGLE-BOARD COMPUTER

DESCRIPTION

The PCA8501 is a general-purpose single-board computer that is composed of a memory and an I/O interface around the M5L8085AP 8-bit microprocessor and fabricated on a single 125 x 145mm printed circuit board. As it has been designed so compactly in its dimensions, it may be easily attached to the board currently used. There are two types available: the PCA8501G01, which is implemented with the M5L2114LP NMOS RAMs, and the PCA8501G02, is implemented with the M58981S CMOS RAMs.

FEATURES

Type	Contents
PCA8501G01	Consists of the single-board computer only. Two M5L2114LP NMOS RAMs are mounted for its RAM, excluding both a battery backup circuit and a wait signal generation circuit, and one M5L2716K EPROM is attached separately.
PCA8501G02	Consists of the single-board computer only. Two M58981S CMOS RAMs are mounted for its RAM, including a battery backup circuit and a wait signal generation circuit, and one M5L2716K EPROM is attached separately.

- A single-board computer comprised of the CPU, memory, I/O interface and a timer.
- Capacity of EPROM: 4K bytes (max)
- Capacity of RAM: 1K bytes
- Programmable I/O port: 48 bits (8-bit x 6)

- Internally contained I²L timer: One of the following 8 timer outputs can be selected (1.6 μ s, and 0.1, 0.2, 0.4, 0.8, 1.6, 3.3 and 6.6ms).
- Single 5V power supply
- Compact dimensions (L x W x H): 125 x 145 x 17mm

APPLICATIONS

- Personal computers
- Small automatic testing or control equipment
- Data-communication terminal equipment
- Data loggers and data-collection equipment
- Process-control equipment
- Instrument monitoring controllers

FUNCTION

The PCA8501 is a highly reliable single-board computer designed around Mitsubishi's M5L8085AP CPU (equivalent to Intel's 8085A) and its LSI family. The 8-bit parallel CPU is fabricated by the N-channel silicon-gate ED-MOS process. The PCA8501 comes with 4K bytes of electrically programmable read-only memory (EPROM) in the form of two M5L2716Ks and 1K bytes of random-access memory in the form of two M5L2114LPs or two M58981Ss.

For its I/O ports, the PCA8501 contains two M5L8255AP programmable peripheral interfaces (PPI) providing 8 bits x 6 — 48 bits programmable ports.

A timer circuit and a battery backup circuit (which is available only for the PCA850G02) are mounted on the board, allowing timer interrupt and memory backup.

MELCS 85/2 SINGLE-BOARD COMPUTER

OPERATIONS

As soon as the power is applied, the M5L8085A CPU is reset by the power-on reset circuit and starts to execute the program from the address 0000₁₆.

The low-order 8 bits of the address are multiplexed with data and sent out through the CPU terminals. They are latched in the address latch circuit so as to compose an address bus with the high-order 8 bits of the address.

If an external extension signal is used, it makes easy the external expansion of memory capacity for both ROMs and RAMs.

Use of CMOS RAMs enables memory backup by means of the battery backup circuit and batteries so that the contents of the RAM are maintained even after the power is turned off.

Either of the ROMs, M5L2708K (1K bytes) or M5L2716K (2K bytes) can be used by using a jumper socket, but the standard version is arranged for the use of the M5L2716K.

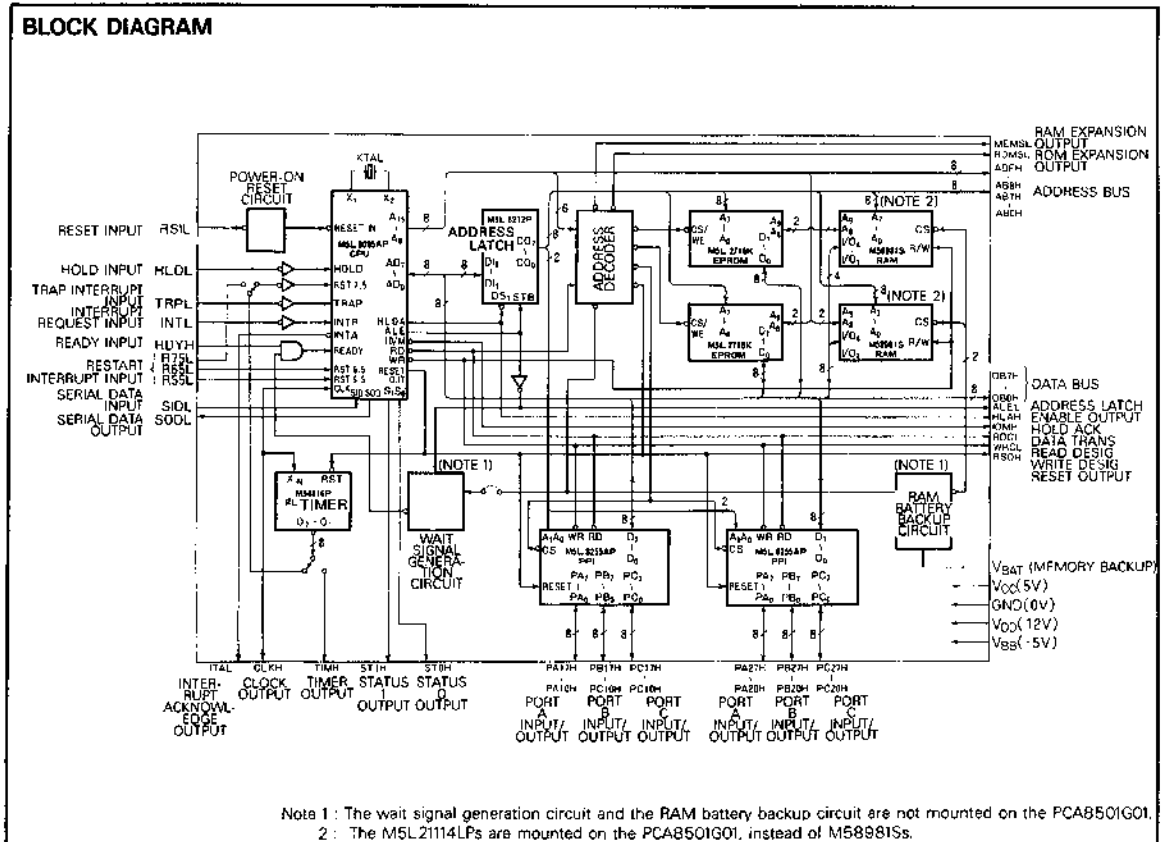

Parallel data can be read/written through the PPTs, and serial data through the SID and SOD of the M5L8085AP CPU.

As the timer IC is provided on the board, it enables timer interrupt by means of the RST 7.5 or timer output to the external circuit.

BLOCK DIAGRAM NOTATION

Name of block	Function
CPU power-on reset	Execution is carried out in accordance with the contents of a program. System reset signal is generated when the power is turned on.
Address latch circuit	Latches the low-order 8-bit address signal on the multiplexed data bus.
Address decoder	Decodes the high-order bits of the address, and generates the memory and I/O chip select signals.
EPROM	Both erasable M5L2716K and M5L2708K can be used.
RAM	Allows the use of the M5B981S CMOS RAMs other than the M5L2114LPs, which enables battery backup.
RAM battery backup circuit	Enable maintaining the contents of the memory by the backup circuit with batteries in use, when the CMOS RAMs are used.
I/O port (PPI)	It is a programmable I/O interface consisting of 48-bit I/O signal terminals, corresponding to six 8-bit I/O ports.
Timer	This generates 7 different signals after dividing the clock signal from the CPU, allowing RST 7.5 interrupt by using a jumper wire.
Wait signal generation circuit	When the CMOS RAMs are in use, wait signal is generated to wait one clock time. (This feature is not available in the PC8501G01.)

BLOCK DIAGRAM

MELCS 85/2 SINGLE-BOARD COMPUTER

SPECIFICATIONS

Processing Method

Method: 8-bit parallel operation
 CPU: M5L8085AP
 Word length:

Instruction: 8, 16, 24 bits

Data: 8 bits

Cycle time:

Basic cycle time: 1.6µs

CPU clock frequency:

2.4576 MHz ±1% (Ta=0~55°C, Vcc=5V ±5%)
 (Quartz oscillation frequency: 4.9152 MHz ±1%)

Memory Address and Memory Capacity

EPROM (M5L2716K)

Memory address:

#1: 0000₁₆~07FF₁₆

#2: 0800₁₆~0FFF₁₆

Memory capacity:

#1: 2K bytes (An EPROM is fitted to the standard product)

#2: 2K bytes (Only a socket is provided on the standard product)

RAM (M5L2114LP x 2 or M58981S x 2)

Memory address:

4000₁₆~43FF₁₆

Memory capacity:

1K bytes

Externally expandable up to a maximum of 64K bytes

I/O Address and I/O Capacity

I/O address:

PPI (M5L8255AP)

I/O port	Signal description	Address
PPI #1	PA	PA10H~PA17H 6000 ₁₆
	PB	PB10H~PB17H 6001 ₁₆
	PC	PC10H~PC17H 6002 ₁₆
	C.W.	Control word 6003 ₁₆
PPI #2	PA	PA20H~PA27H 7000 ₁₆
	PB	PB20H~PB27H 7001 ₁₆
	PC	PC20H~PC27H 7002 ₁₆
	C.W.	Control word 7003 ₁₆

As two PPIs (Programmable Peripheral Interfaces) are provided on the board, the PC8501 has I/O ports of 48 bits (8-bit x 6) in total.

Interrupt

5 Interrupts:

Five interrupts such as TRAP, RST 7.5, RST 6.5, RST 5.5, and INTR are provided. The TRAP has the highest priority, while the INTR has the lowest priority. The RST 7.5 will enable timer interrupt by means of a jumper wire.

Connectors

For bus extension (connector J1):

Straight pin header, T-type, 50 pins

For I/O port connection (connector J2):

Angle pin header, L-type, 60 pins

PIN CONFIGURATIONS

MELCS 85/2 SINGLE-BOARD COMPUTER

Memory and I/O Addresses

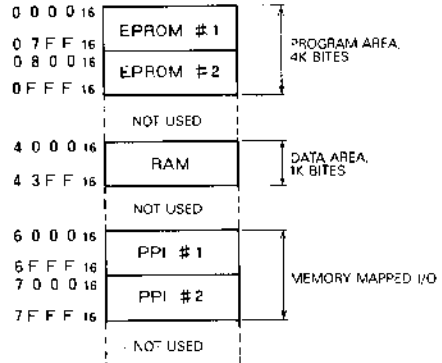

As memory and I/O addresses are fixed in this single-board computer, it is necessary to designate extra addresses besides those already assigned, if any additional external memory or I/O devices are to be employed.

I/O Address

	PPI # 1				PPI # 2			
	Port A	Port B	Port C	C.W.	Port A	Port B	Port C	C.W.
Memory mapped I/O address	6000 ₁₆	6001 ₁₆	6002 ₁₆	6003 ₁₆	7000 ₁₆	7001 ₁₆	7002 ₁₆	7003 ₁₆

The following addresses are inhibited from expanding externally, because there is no perfect redundancy in the decode of the PPIs: 6000₁₆ ~ 6FFF₁₆
 7000₁₆ ~ 7FFF₁₆

Memory Address Map

MELCS 85/2 MEMORY AND PARALLEL I/O EXPANSION BOARD

DESCRIPTION

The PCA8506 memory and parallel I/O expansion board is designed to be used with the PCA8501 or PCA8540 single-board computer. Memory, parallel I/O ports, and a timer are assembled on a 145 x 125 mm printed circuit board. The PCA8506 can easily be attached to the PCA8501 or PCA8540 single-board computer by using a bus-extension connector.

FEATURES

- Expansion board consisting of memory, parallel I/O ports, and a timer
- Memory capacity: 12K bytes
(expandable in units of 2K bytes RAM or 2K bytes ROM)
- Programmable ports: 48 bits (8 bits x 6 ports)
- Programmable timer: 16 bits x 3
- Power supplied from the PCA8501 or PCA8540
- Compact dimensions (LxWxH): 125x145x17 mm

APPLICATIONS

- Personal computer expansion module
- Control equipment module

FUNCTION

The PCA8506 expansion board consists of up to 12K bytes memory, six 8-bit parallel I/O ports, along with 3 16-bit counters for timer application. The memory can easily be expanded in units of 2K bytes up to 12K bytes using any combination of M5L2716K EPROMs or M58725P static RAMs. The parallel I/O ports consist of 2 (programmable peripheral interfaces) (PPIs) each composed of 3 8-bit I/O ports. The timer consists of a programmable interval timer (PIT) which has 3 16-bit timer counters.

MELCS 85/2 MEMORY AND PARALLEL I/O EXPANSION BOARD

OPERATION

The address bus of the CPU is connected to other boards through the address bus buffer. The data bus is connected to the data input/output pins of memory, I/O, and a timer through the bidirectional data bus buffer. The data bus buffer is in an active state only when an IC device on the board is selected. The buffer is ready for output to external units only when the read signal RDCL from the CPU goes low.

Six 24-pin sockets are provided for memory, which are designed for M5L2716K EPROMs. Since the M5L2716K is compatible with the M58725P except for V_{pp}/WR (pin 21), if pin 21 is switched on the connector corresponding to a socket, a M58725P static RAM can be used in place of a M5L2716K EPROM in that socket. It is therefore possible to mix ROMs and RAMs in any order desired by the user.

Since addresses have been allocated on the memory map for the 2 parallel I/O ports and a timer the contents can be read and written in the same way memory is accessed.

All ports of PPIs are initiated to the input mode after the power is turned on, and remain in this mode until a control word is written. As soon as the counter is set by the control word, following the operation mode, the timer will begin to count.

DIMENSIONS

(LxWxH) 125x145x17 mm

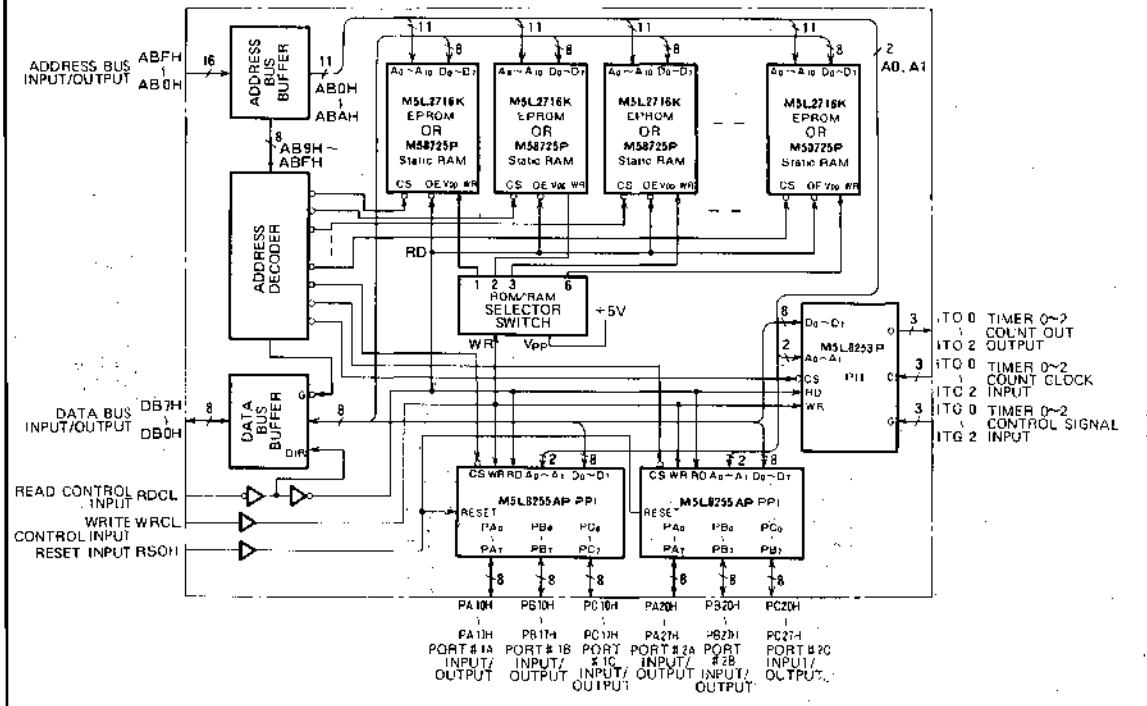

MEMORY AND I/O ADDRESSING

Both memory and I/O addresses can select two areas. When this board is added, different address areas from those of the main board should be selected.

MELCS 85/2 MEMORY AND SERIAL I/O EXPANSION BOARD

DESCRIPTION

The PCA8507 memory and serial I/O expansion board is designed to be used with the PCA8501 or PCA8540 single-board computer. Memory, a serial I/O port and a timer are assembled on a 145 x 125 mm printed circuit board. The PCA8507 can easily be attached to the PCA8501 or PCA8540 single-board computer by using a bus-extension connector.

FEATURES

- Expansion board consists of memory, a serial I/O and a timer
- Memory capacity: 12K bytes
(expandable in units of 2K bytes RAM or 2K bytes ROM)
- Serial I/O port and TTL, RS-232-C interface
- Programmable timer, 16 bits x 3
- Power supply from the PCA8501 or PCA8540
- Compact, dimensions (LxWxH): 125x145x17mm

APPLICATIONS

- Personal computer expansion module
- Control equipment module
- Data terminal module

FUNCTION

The PCA8507 expansion board consists of up to 12K bytes of memory, serial I/O port, interface for TTL level and RS-232-C output, along with 3 16-bit counters for timer application.

The memory can easily be expanded in units of 2K bytes up to 12K bytes using any combination of M5L-2716K EPROMs and M5825P static RAMs. The serial I/O port consists of a universal synchronous asynchronous receiver transmitter (USART) for changing parallel/serial and formatting the string in the specified format. Interfaces are provided between the USART and the TTL level or RS-232-C output. The interface is selected by a jumper connection. The timer consists of a programmable interval timer (PIT) which has 3 16-bit timer counters. One of the timers is used by the USART for controlling the baud rate of serial data transfer.

MELCS 85/2 MEMORY AND SERIAL I/O EXPANSION BOARD

OPERATION

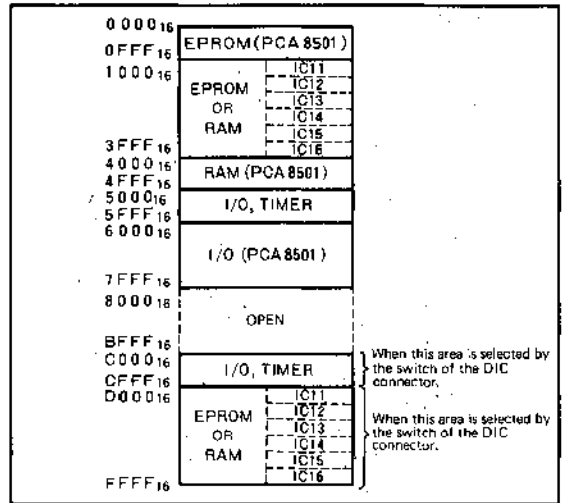

The address bus of the CPU is connected to other boards through the address bus buffer. The data bus is connected to the data input/output pins of memory, I/O, and a timer through the bidirectional data bus buffer. The data bus buffer is in an active state only when an IC device on the board is selected. The buffer is ready for output to external units only when the read signal RDCL from the CPU goes low.

Six 24-pin sockets are provided for memory, which are designed for M5L2716K EPROMs. Since the M5L2716K is compatible with the M58725P except for Vpp/WR (pin 21), if pin 21 is switched on the connector corresponding to a socket, an M58725P static RAM can be used in place of an M5L2716K EPROM in that socket. It is therefore possible to mix ROMs and RAMs in any order desired by the user.

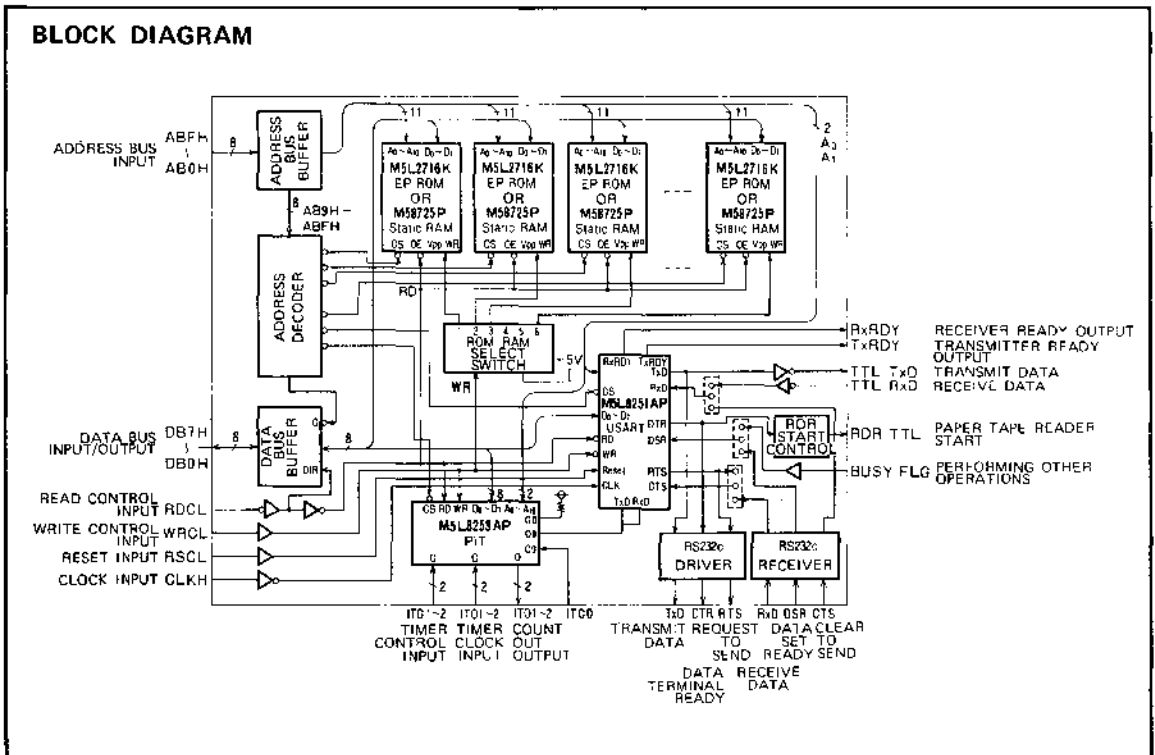

Since addresses have been allocated on the memory map for the USART as a serial I/O port and a timer the contents can be read and written in the same way memory is accessed. TTL and standard RS-232-C interfaces are built on the board to interface between the serial I/O port and peripheral devices. Selection of one or the other interface is done by a jumper in the jumper socket.

sists of 3 16-bit counters. One of the counters is used as a clock by the USART in setting the baud rate.

MELCS 85/3 VOICE GENERATING SINGLE-BOARD COMPUTER

DESCRIPTION

The PCA8520 is a voice generating single-board computer. It consists of an 8-bit M5L8085AP microprocessor, memory, I/O interface, voice reproducing IC, and is fabricated on a single 125 x 145 mm printed circuit board. Voice data is first recorded in EPROMs and is changed into voice data through delta modulation system.

FEATURES

Type	Contents
PCA 8520 G01	Single-board computer only
PCA 8520 G02	PCA8520G01 single-board computer 1 pc. M5L2716K (007) EPROM for control program storage 1 pc. (008-014) EPROMs for voice data storage 7 pcs. Speaker 1 pc. Instruction manual 1 vol

- A single-board computer complete with CPU, memory, I/O interface and voice reproducing IC.
- Storage capacity of the EPROM:
 - using M5L2716K: 16K bytes (max)
 - using M5L2732K: 32K bytes (max)

- Storage capacity of the RAM: 256 bytes
- I/O interface: 24 bits (8 bits x 3)
- Voice recording time:
 - using M5L2716K: 9 seconds (max)
 - using M5L2732K: 18 seconds (max)
- Voice maximum output power (at $V_{CC2} = 9V$): 1W (typ)
- Compact dimensions (LWH) 125x145x20 mm

APPLICATIONS

- An alarm device to be used in factories, offices, etc.
- A recorded sales message device
- An audio output information device
- A device to give voice operation instructions
- Numerical value response for measurement instruments and calculators

FUNCTION

The PCA8520 is a single-board computer with a voice generating function, and is designed around Mitsubishi's M5L8085AP CPU, its LSI family, and voice reproducing IC. It comes with 16K bytes (M5L2716K x 8) or 32K bytes (M5L2732K x 8) of read-only memory and 256 bytes (M5L2112AP) of random-access memory. The

MELCS 85/3 VOICE GENERATING SINGLE-BOARD COMPUTER

PCA8520 has 1 M5L8255AP programmable peripheral interface (PPI) which offers 24 bits (8 bits x 3) of programmable I/O port.

Voice reproducing is performed through an IC for delta demodulation, a low-pass filter, and a power amplifier. Voice data in the ROM can be sent to the voice reproducing circuit by program control, and then output with 1W of power.

A nine-second message can be output when using 8 M5L2716Ks. An eighteen-second message is possible when using 8 M5L2732Ks. Voice data can be output at both syllable- and word-levels, and can be edited under program control.

OPERATION

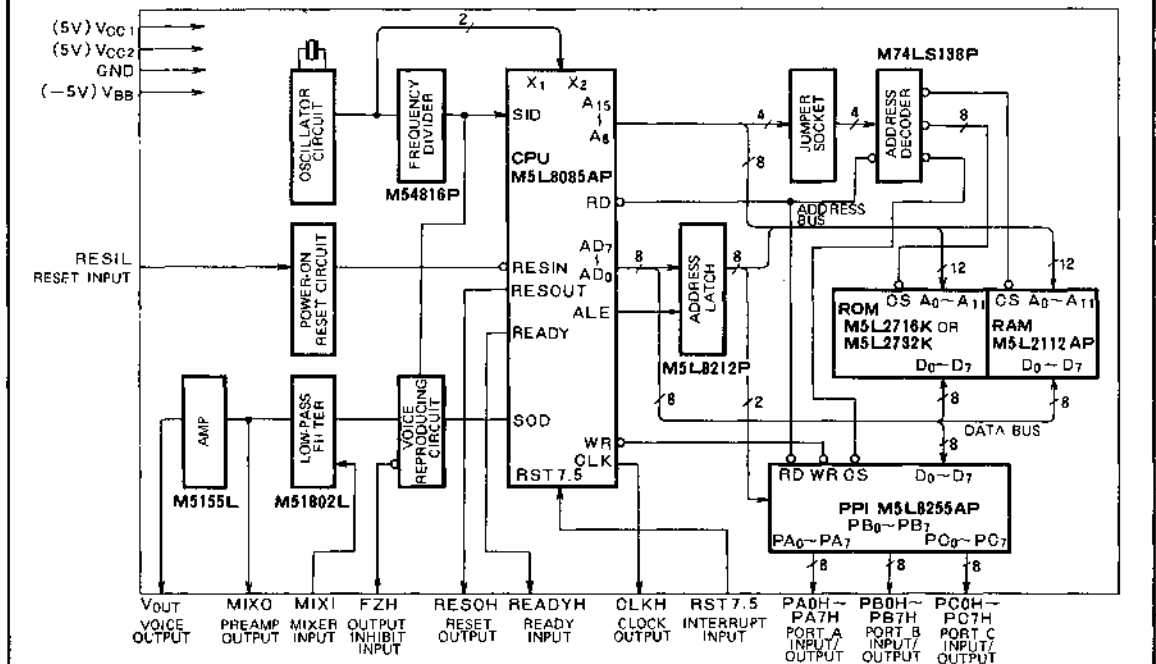

The M5L8085AP CPU executes programs stored in the ROM synchronizing with a quartz oscillator clock. The frequency of this clock is divided by 256 and is supplied to the SID terminal of the CPU and the input of the IC for delta demodulation. The voice can be generated using voice data. This voice data, which is stored in the ROM, is converted parallel to serial and is sent to the SOD terminal in sequence from the most-significant bit.

The M5L2112AP RAM can be used as a data stack, etc. The M5L8255AP PPI can be used for external data inputs or outputs.

BLOCK DIAGRAM NOTATION

Name	Function
Reset circuit	A system reset signal is generated when power is turned on.
Oscillator circuit	The clock is supplied to the CPU and the frequency divider circuit.
Frequency divider circuit	The frequency of the oscillator clock is divided by 256 and is supplied to the voice reproducing circuit.
CPU	Executes the program.
Address latch	As the data and low-order address signals are sent from AD ₆ ~AD ₇ terminals of the CPU using 1-sharing technique, only the address signal is latched into the address latch circuit by the ALE timing signal.
Jumper socket	M5L2716Ks or M5L2732Ks can be selected by simply changing the jumper wire in the jumper socket.
Address decoder	Generates the selection signal of a ROM, RAM, and PPI decoding the high-order bits of the address signal.
ROM	Memory to store program and voice data.
RAM	Memory to store data stack, temporary data, etc.
PPI	Is used for external data inputs and outputs.
Voice reproducing circuit	Reproduces voice waveform from the digital signal which is sent from the SOD terminal of the CPU.
Low-pass filter	This filter only passes low-frequency voice signals.
Amplifier	Voice signal passed through the low-pass filter is amplified to 1W.

MELCS 85/2 COLOR TV DISPLAY SINGLE-BOARD COMPUTER

DESCRIPTION

The PCA8540 is a single-board computer of the MELPS 85 LSI family. The TV interface is fabricated on a single 125 x 145 mm printed circuit board. It provides for screen displaying with a resolution of 256 x 192 elements maximum in 2 colors, up to 8 colors in semigraphic 4, or up to 64 ASCII coded characters. A simple connection to the antenna terminal allows it to be used with a home color TV receiver. The PCA8540 also produces composite video signals that can be connected directly to the video monitor.

FEATURES

Type	Function
PCA8540G01	For home-use TV with output of NTSC system signals for Japan Channel 1 or 2 Contains no EPROMs Contains only one M58725P for screen memory
PCA8540G02	For video monitor TV with monochrome video monitor signals Contains no EPROMs Contains only one M58725P for screen memory

- A single-board computer complete with CPU, memory, I/O and TV interface
- Enables up to 256(H) x 192(V) elements graphic display on a home color TV receiver (or monochrome video monitor)
- Up to 64 characters can be displayed

- The 64 ASCII characters are stored on an internal character generator ROM and can be displayed together with semigraphics 4 mode
- Provide 9 colors on screen: green, yellow, blue, red, light gray, cyan, magenta, orange and black
- ROM 4K bytes (max) + RAM 256 bytes or ROM 2K bytes + RAM 2.25K bytes
- Programmable I/O port with timer: 22 bits
- Compact: dimensions (LxWxH): 125x145x20 mm
- Expandable memory and I/O (using memory I/O expansion board PCA8506 or PCA8507)

APPLICATIONS

- TV games
- Personal computer
- Data terminal with graphic capability
- Display terminal for microcomputer systems
- Commercial advertising display
- Slave computer for a MELCS 85/2 system

FUNCTION

The PCA8540 is a single-board computer, with color TV display capabilities designed to be compatible with the Mitsubishi M5L8085AP CPU and its LSI family as well as the VDG (video display generator) LSI M5C6847P-1. The PCA8540 comes with 4K bytes of ROM + 256 bytes

MELCS 85/2 COLOR TV DISPLAY SINGLE-BOARD COMPUTER

of RAM or 2K bytes of ROM + 2,304 bytes of RAM along with 3 I/O ports (22 bits). ROM, RAM and I/O are provided by the M5L2716K x 2 + M5L8155A or M5L2716K + M58725P + M5L8155A.

The TV interface of the G01 system consists of a VDG LSI M5C6847P-1 (TV interface), an M51342P RF modulator IC and 3 M58725P 16K static RAMs which are used for screen display memory. The G02 system has a video amp circuit instead of an M51342P.

As the various display modes can be programmed using an M5C6847P-1, the following can be displayed.

- Character display, pattern stored on internal ROM
- Reverse character display (one character)
- Semigraphics 4 (up to 8 colors)
- Semigraphics 6 (up to 4 colors)
- 64 x 64 4 colors • 128 x 64 2 colors
- 128 x 64 4 colors • 128 x 96 2 colors
- 128 x 96 4 colors • 128 x 192 2 colors
- 128 x 192 4 colors • 256 x 192 2 colors

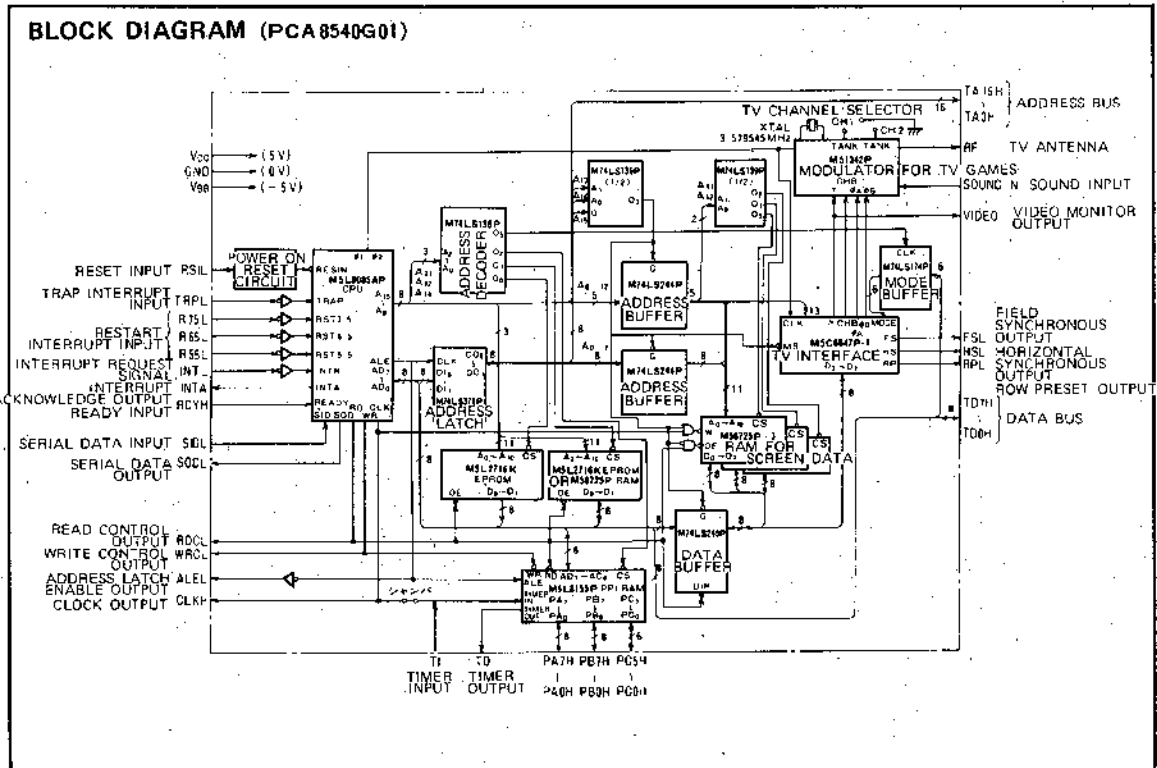

The PCA8506 and PCA8507 are used, for memory I/O expansion boards, to expand to a maximum of 16K bytes of ROM or RAM, an RS-232-C serial interface can be used.

OPERATIONS

The program for the M5L8085AP CPU is normally stored on 2 M5L2716K EPROMs (2 x 2K bytes) and an M5L-8155P RAM (256 bytes) but 1 M5L2716K EPROM can be replaced by an M58725P RAM (2K bytes). Data transmission to and from external sources is done through the ports of the M5L8155P.

There is a data buffer between the M5C6847P-1 and the CPU on the address and data bus. This allows the M5C-6847P-1 to operate independently of the CPU when reading information from the M58725P RAM for screen data. It adds synchronous signal before it is output serially to the M51342P TV game modulator. The signal includes the intensity and color signals which are modulated by the M51342P into NTSC system TV signals for channel 1 or 2. The M5C6847P-1's composite video signal can be used for input to the monochrome video monitor.

When the CPU accesses the RAM, addresses 6000₁₆ ~ 77FF₁₆ for screen data, \overline{MS} of the M5C6847P-1 will be at low-level and the address output will be in high-impedance state. During this period the CPU can change the contents of the RAM for screen data. The CPU can also change the display mode of the M5C6847P-1 through the data bus by accessing mode set address 4800₁₆.

MELCS 85/2 COLOR TV DISPLAY SINGLE-BOARD COMPUTER

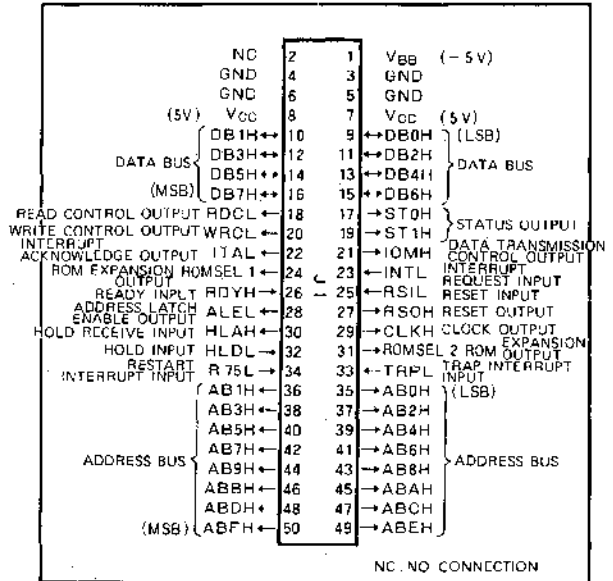

SPECIFICATIONS

Item	Description
Method	B bit parallel operation
CPU Component	Mitsubishi's M518085AP (equivalent to the inte. 8085A)

MEMORY ADDRESS MAP

MEMORY CAPACITY AND I/O EXPANSION

The capacity of the PCA8540 can be easily expanded by the addition of other boards such as the PCA8506 or PCA8507.

PCA8506 (ROM, RAM and Parallel I/O Extension)

- Memory capacity 12K bytes (Note 6)
- Programmable ports 48 bits 8 bits x 6
- Programmable timers 16 bits x 3
- Small size, dimensions (LxWxH) 145x125x17 mm

PCA8507 (ROM, RAM and Serial I/O Extension)

- Memory capacity 12K bytes (Note 6)
- Serial port (RS-232-C or TTL Level) 1 port
- Programmable timers 16 bits x 3
- Small size, dimensions (LxWxH) 145x125x17 mm

Note 6: The memory can easily be expanded in units of 2K bytes up to 12K bytes using any combination of M5L2716K EPROMs and M58725P static RAMs.

MITSUBISHI MICROCOMPUTERS PCA7002G01, G02

MELCS 70/2 SPEECH SYNTHESIZER SINGLE-BOARD COMPUTER

DESCRIPTION

The PCA7002 consists of a controller (single-chip micro-computer) and speech synthesizing LSI housed on a compact 125 x 145mm printed circuit board, capable of generating speech output. Using the PARCOR method, previously analyzed data is stored in EPROM memory and used as the voice data basis for speech synthesis.

Two versions of the single-board computer are available, the PCA7002G02 consisting of a controller and EPROM, and the PCA7002G01 consisting of the basic board alone without a controller and EPROM.

Type	Configuration
PCA7002G01	Board only. No instruction manual supplied. (Note 1)
PCA7002G02	The basic board plus a speech sample stored in a single M5L2732K and the standard program stored in a single M5L8049-005P. In addition, an instruction manual is provided. (Note 2)

Note 1. The PCA7002G01 controller and speech data memory section consists of IC sockets only. However, the synthesizer and other speech output circuits are provided.

2. The PCA7002G02 is provided with the following sample voice in Japanese (female speaker).

(1) This is the Mitsubishi Electric Corporation.

(2) This voice has been synthesized with the use of the Single-chip synthesizer

(3) Welcome.

(4) May I help you?

(5) Please wait a moment

FEATURES

- Single-board computer capable of PARCOR system speech generating using LSI devices.
- Speech data memory 16K bytes (max)
- Speech recording time 100s (max)
- Speech output power 5.5W (max)
- Small package 125(W)x145(L)x30(H) mm

APPLICATIONS

Clocks, control equipment, vending machines, bus annunciators, copying machines, alarm devices.

FUNCTION

The PCA7002 is a speech generating and output singleboard computer consisting of a controller, speech synthesizer LSI, speech data memory, filter, and amplifier circuits. An M5L8048-XXXP 8-bit single-chip controller can be used, and while an M5L8049-XXXP or M5L8748S may be used, an M5L8049-005P which contains the standard program has been provided.

An M5L2716K or M5L2732K may be used as a speech data memory and four M5L2732K devices will allow 60 to 100 seconds of speech output.

In addition, a filter and amplifier circuits are provided on the printed circuit board as well, enabling a maximum speech output power of 5.5W.

MITSUBISHI MICROCOMPUTERS PCA7002G01, G02

MELCS 70/2 SPEECH SYNTHESIZER SINGLE-BOARD COMPUTER

FUNCTIONAL DESCRIPTION

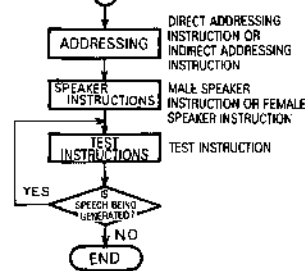

The M58817AP may be controlled by using the following eight instructions which are set up using four data bus lines (DQ₀ ~ DQ₃) and one strobe line (ISYNC).

1. Addressing instruction: Used to set phrase ROM addresses
2. Indirect addressing instruction: Used to indirectly set phrase ROM addresses
3. Bit read instruction: Used to shift into a 4-bit shift buffer 1-bit of contents from the phrase ROM
4. Data transmission instruction: Output the contents of the 4-bit shift buffer
5. Test instruction: Test whether speech generation has been completed
6. Male speaker instruction: Start instruction for voice generation (male)
7. Female speaker instruction: Start instruction for voice generation (female)
8. Stop instruction: Halts the generation of speech

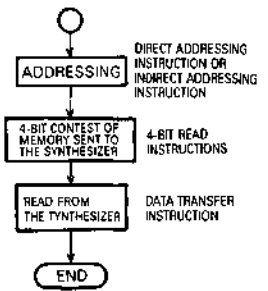

In accordance with the above instructions, the controller reads speech generation instructions for the synthesizer and data from the speech data memory.

The diagram below illustrates the flow of speech synthesis instructions and data.

Speech synthesis instructions

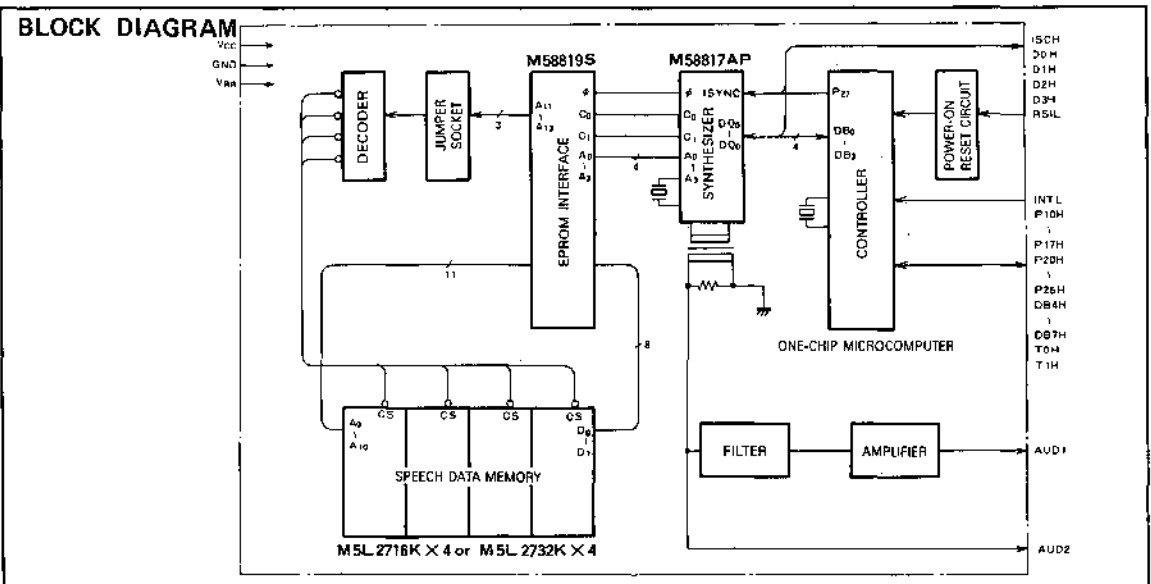

Data read

OPERATION OF BASIC BLOCKS

Name	Function
Controller	Provides speech processing in accordance with the program
Power-on reset	Generates a controller reset signal upon power-on
Synthesizer	Performs data transfer and speech generation under the control of the controller
EPROM interface	Reads speech data from the speech data memory and sends it to the synthesizer
Jumper socket	Set to specify M51 2716K or M51 2732K devices
Decoder	Outputs the speech data memory selection signal based on the address signals output by the EPROM interface
Speech data memory	Memory used to store speech data
Filter	Eliminates high-frequency noise components from the speech output of the synthesizer
Amplifier	Provides power amplification to an output of 5 W, maximum, of the speech signal from the filter

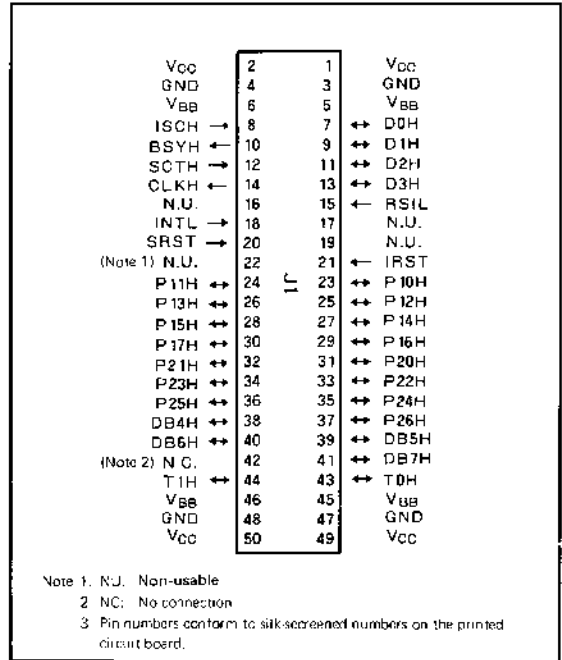

MELCS 70/2 SPEECH SYNTHESIZER SINGLE-BOARD COMPUTER

SPECIFICATIONS

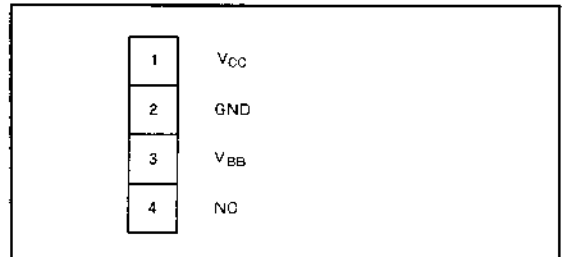

Parameter	Specification
Control method	8-bit parallel processing
Control LSI	M5L8049-XXXXP, M5L8049-XXXXP, and M5L8748K (the PCA7002G02 includes an M5L8049-005P containing the standard program)
Cycle time	Basic cycle 4.19 μ s (3.579545MHz crystal)
Speech synthesis method	PARCOR
Speech synthesis LSI	M58817AP
Speech data memory	16K-byte, maximum (M5L2732K \times 4) Addressable 0000 ₁₆ ~03FFF ₁₆ 8K-byte, maximum (M5L2716K \times 4) Addressable 0000 ₁₆ ~01FFF ₁₆
Data rate	1.96K bit/s (maximum) 3.92K bit/s (maximum) (Selectable by means of on-board jumpers)
Speech synthesis output time	60 seconds (minimum) using 1.96K bit/s transfer rate (Memory capacity/1960) 30 seconds (minimum) using 3.92K bit/s transfer rate (Memory capacity/3920)
Speech output power	5.5W (4 Ω speaker) 2.75W (8 Ω speaker)
Interrupt	1 factor, 1 level
Power supply	+5V \pm 5%, -5V \pm 5% When using an M5L8049-005P controller and four M5L2732K data memories: 800mA (maximum) @+5V 270mA (maximum) @-5V
Connectors	50-pin angled pin header (I/O port) 4-pin angled-pin header (power supply) 4-pin angled-pin header (speech output)
Dimensions	*25(W) \times 145(L) \times 30(H)mm

MICROCOMPUTER SUPPORT SYSTEM

MITSUBISHI MICROCOMPUTERS PCA0803

MELCS 8/2 PROGRAM CHECKER

DESCRIPTION

The PCA0803 program checker is simple to use, and is suitable for testing the functioning of equipment that employs the PCA0801 single-board computer and the PCA0802 memory and I/O expansion board without requiring any extra software monitor program.

The PCA0803 program checker is useful both in design evaluation and system troubleshooting in field maintenance.

FEATURES

- Single-step function: After halting the CPU at any designated address, allows step-by-step execution of the program instructions in successive single machine cycles.
- Breakpoint function: Halts the CPU at any designated address. Program execution can then be started from this address.
- Memory read/write function: Enables data to be read or written from/to any desired memory location.
- Reset function: Can reset the M5L8080AP CPU.
- Complete with bus cable: A special bus cable, approx. 800 mm long, is provided for connection.
- Supply voltage: 5V \pm 5%
- Supply current: 0.6A (typ)
- Compact dimensions (L x W x H): 170 x 200 x 27mm

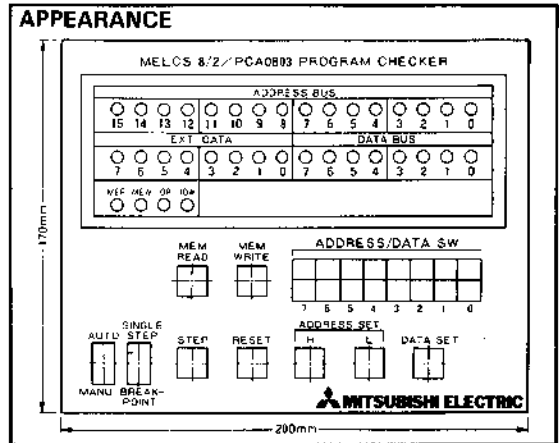

APPLICATIONS

- For design and evaluation of MELCS 8/2 and MELCS 85/2 Board Computer application systems.

FUNCTION

Software and hardware debugging can be readily achieved by simply connecting the PCA0803 program checker to the equipment tested. Because the PCA0803 is a hardware device, it does not require any extra software monitor programs. The PCA0803 program checker is capable of performing single-step program execution, breakpoint operation, CPU resetting, and memory read/write operations.

APPEARANCE

Mitsubishi PCA0803 program checker

MELCS 8/2 PROGRAM CHECKER

FUNCTION

1. Display Panel

The display panel indicates the operating status of the address bus, data bus and control signals.

2. Address/Data Switches

The ADDRESS/DATA switches are used in setting the address and data for the designated RAM area.

3. H/L Address Set Switch

The H/L ADDRESS SET switch is used in latching the address to the address/data latch circuit. The address is latched to the address/data latch circuit in two operations, the most significant 8 bits and then the least significant 8 bits.

4. Data Set Key

This key is used for data setting.

5. MEM Read/MEM Write Keys

These keys are used in reading or writing data from/to the designated memory location.

6. Manu/Auto Selection Switch

In the AUTO position, the system executes sequential program instructions. In single-step or breakpoint operation, this switch should be set to the MANU position.

7. Single Step/Breakpoint Selection Switch

In the SINGLE STEP position, depression of the STEP key causes step-by-step execution of the program instructions during successive single machine cycles. When the switch is set to the BREAKPOINT position, the program execution halts at the designated address.

8. Step Key

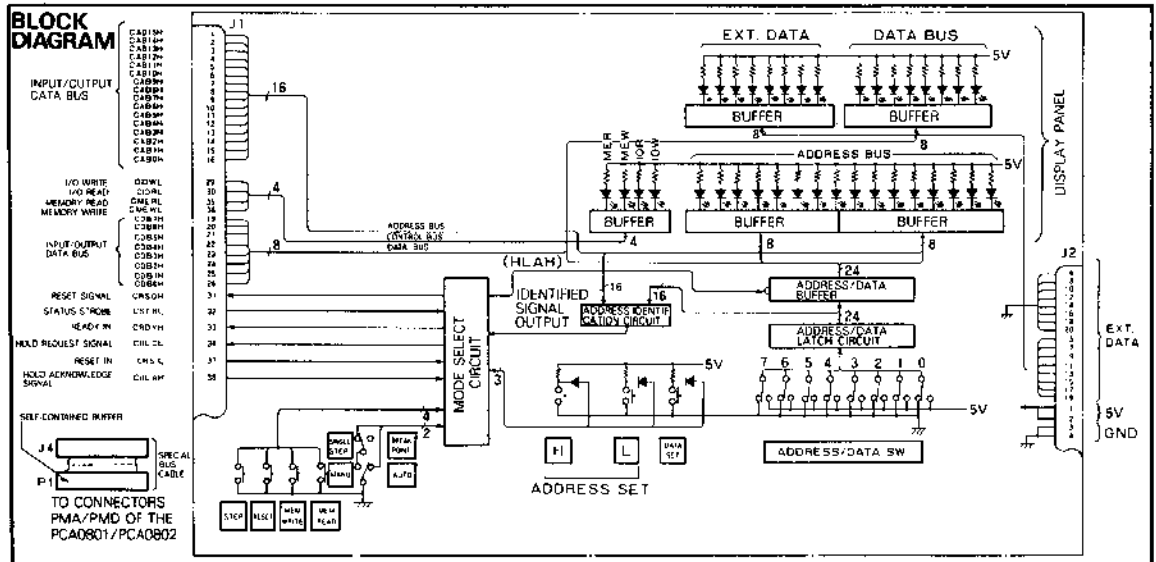

Each time this key is depressed, it executes one program step.

9. Reset Key

This key resets the M5L8080AP CPU. The program counter is cleared to '0', and both the data bus and the address bus are kept in the floating state.

10. Mode Selection Circuit

This circuit receives various signals from each of the operational switches and sends out selected signals corresponding to the mode assigned.

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Limits	Unit

V _{IL}	Low-level input voltage	0		0.65	V

DESCRIPTION

The PC4000 is a debugging machine for use with single-chip microcomputers. It is intended for use as a general purpose debugging machine for support of single-chip micro-computer hardware and software.

FEATURES

- Usable for RAM-based program debugging
- Connectable to the user system via a DIL socket or connector
- Built-in EPROM (2716, 2732) writer function
- Uses serial data transfer for two-way data transfer with the host machine (e.g. PC9000 cross assembler machine)
- Usable with a variety of single-chip microcomputers by simply replacing a single board
- Print out of internal memory contents is possible by means of an external printer
- Easy-to-carry-about in its compact case, provided with an angle stand

APPLICATIONS

Hardware and software development and program debugging for single-chip microcomputer systems.

CONFIGURATION

The PC4000, as shown in the block diagram, consists of the following hardware elements.

- (1) M5L8085AP monitor CPU
- (2) Serial data input/output interface circuit
- (3) EPROM writer circuit
- (4) Program RAM (10 bits x 4K)
- (5) Keyboard and LED display circuits
- (6) Power supply

The PC4000 is used in conjunction with a dedicated board which allows interface of the PC4000 with the object microcomputer under development. The dedicated board insertion access window is located on the right side of the PC4000. In addition, each dedicated board stores the control program for the monitor CPU. Therefore, when the microcomputer type is changed, the PC4000 can be modified to suit the new type by merely changing the single dedicated board.

DEBUGGING MACHINE

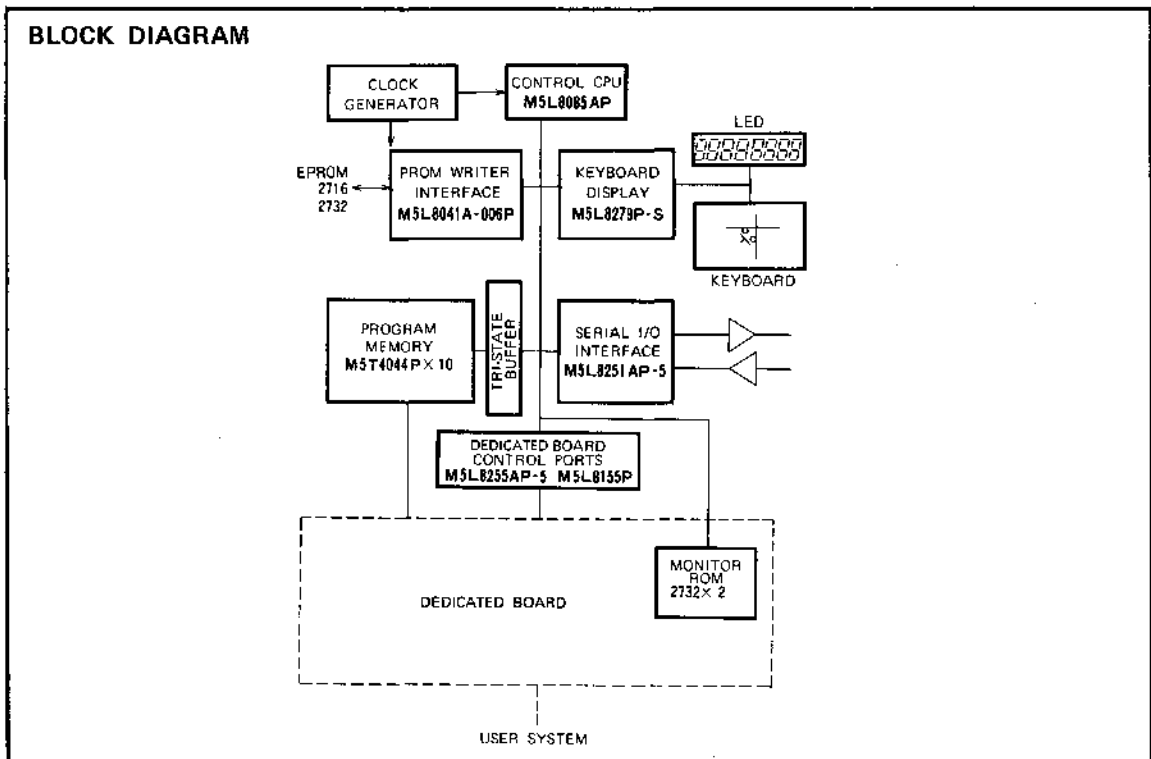

FUNCTIONAL DESCRIPTION

Object programs developed on such devices as the PC9000 cross assembler machine are sent to the PC4000 via the serial input/output interface. The serial data transmission rate can be selected from 1200bps to 9600bps and the interface is a 20mA current loop type. The transmission format is Intel-compatible hexadecimal.

The data in the program memory is executed by the evaluation CPU on the dedicated board. In addition, this

memory contents can be written into 2716 or 2732 EPROM devices or data can be read out of such devices via a 24-pin DIL socket.

The keyboard consists of 12 function keys and 16 numerical keys as well as a single entry key. The LED display is an 8-digit display of 7-segment LED elements used to display data for reference while processing is performed.

DEBUGGING MACHINE

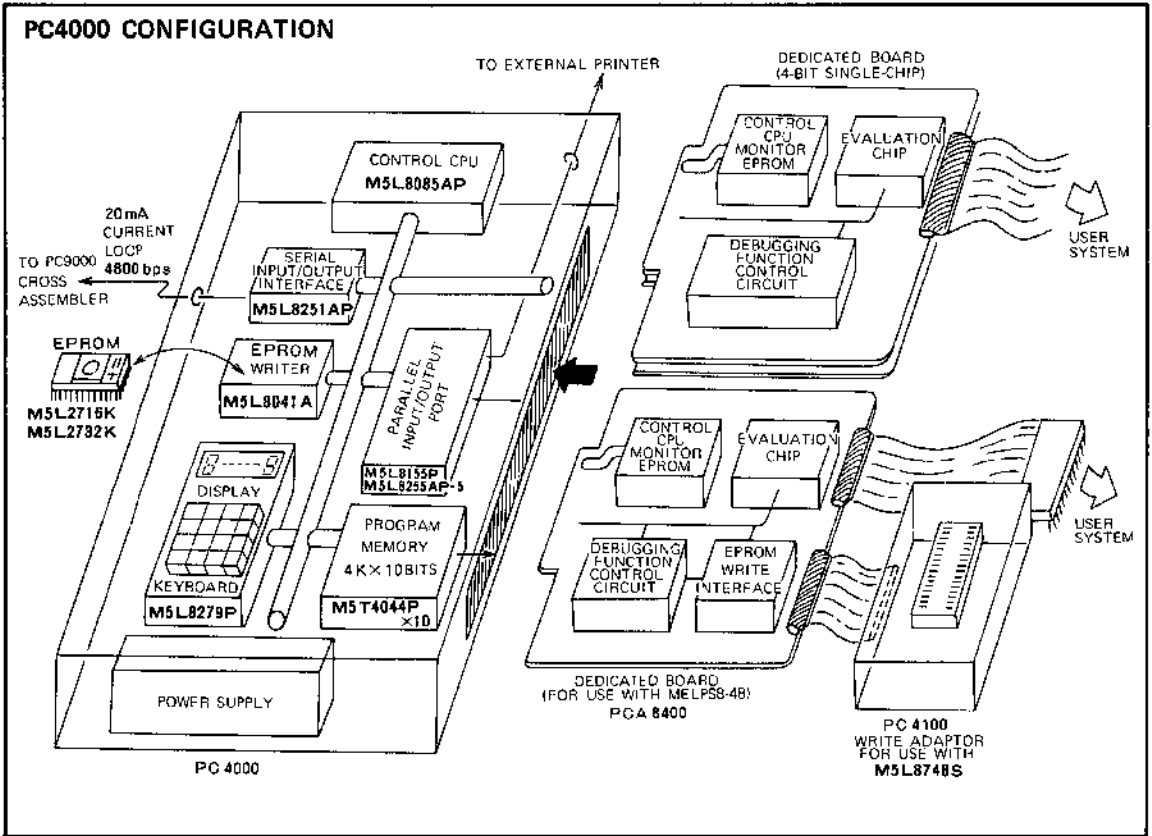

KEY FUNCTIONS (BASIC FUNCTIONS ONLY)

Symbol	Name	Function
SEND	Data transmit key	Converts program memory data to serial data and transmits to an external device
RCV	Data receive key	Receives serial data and writes this data into program memory
PROG	(EPROM) Program key	Writes program memory data into the EPROM inserted in the socket
LOAD	(EPROM) Load key	Sends data from the EPROM inserted in the socket to program memory
PRT	Print key	Data transmit to the optional printer
EXMP	Examine program memory key	Verification/correction of program memory contents
EXMR	Examine register key	Verification/correction of register contents
EXMM	Examine memory key	Verification/correction of RAM contents
RES	Reset key	Reset of program counter
RUN	Run (execute) key	Re-start of program execution at the specified address (real time)
BRK	Break point set key	Sets the break point address
STEP	Single step key	Executes the program one step at a time
O-F	Numerical keys	Used for input of address and data
ENT	Entry key	Effectively enters input numerical data

SPECIFICATIONS

Item	Specification
Method	The system is used with a dedicated board which includes the evaluation chip to perform in-circuit emulation
Applicable microcomputers	M58840-XXXXP M58494-XXXXP M58496-XXXXP M5L8048-XXXXP M5L8049-XXXXP and all other Mitsubishi single-chip microcomputers
Program RAM	Built-in, 4K x 10 bits (250ns access time)
Control CPU	M5L8085AP
Built-in EPROM writer circuit	Usable with 2716 or 2732 devices
Display	7-segment LED, 8 digits
Input	Key switches: Commands: 12 keys Numerical: 16 keys Entry: 1 key
Interface	① 20mA current loop serial input/output interface 4800bps, full duplex, one line (Selectable from 1200 to 9600bps) ② Centronix-compatible parallel interface, one line
Monitor function	Monitor programs for the appropriate object microcomputers are written into the two M5L2732K devices mounted on the dedicated board. Basic Functions <ul style="list-style-type: none"> • Transfer of RAM data with an external system • Read and write of EPROM data • Verification/correction of the built-in program memory (RAM) contents • Execution and halt at any arbitrary program address • Single-step execution of programs • Verification/correction of internal registers, memory, flags
User system connection	Input/output connections to the dedicated board by means of a cable
Dimensions	364 x 257 x 85 mm (excluding handle and key switch tops)
Power supply	AC 100V 100VA
Operating temperature	5 ~ 40°C
Storage temperature	20 ~ 60°C

DEBUGGING MACHINE

SPEECH SYNTHESIS EVALUATION UNIT

DESCRIPTION

The PC7000 is a device intended for use in evaluating speech synthesized from voice data by the PARCOR method under uniform conditions and enables complete evaluation of Mitsubishi speech synthesis products.

FEATURES

- Enables speech synthesis in response to keyed-in information
- Allows free selection of the number of repetitions of speech
- Enables up to a maximum of seven speeches to be continuously generated in response to one keyed input
- Spacing between words is freely settable
- Up to four words may be generated continuously with the programmed spacing
- EPROM data modification may be used to easily change the above programmed sequences
- Built-in power supply and speaker allow immediate use
- A line output is provided for test listening by means of external filters, amplifiers and speakers
- An external switch may be used to easily switch between male and female speakers
- An external switch may be used to select low or high bit rate

FUNCTION

The PC7000 includes a 16-key panel which allows programmed voice sequences to be called up from EPROM memory. In response to a single key up to eight voice instruction steps may be specified, enabling the generation of up to seven words continuously, four words continuously at the specified interval and the generation of repetitions of the entire sequence. The EPROM may be removed by means of a window provided on the PC7000.

Because the PC7000 is provided with a built-in power supply, audio amplifier, and speaker, it can be powered from the commercial power source and used for test listening immediately. In addition, a line output is provided for use with other amplifiers and speakers making connections with other audio equipment simple.

SPECIFICATIONS

Item	Specification
Speech generation section	Low pass filter, highpass filter, main amplifier
Keyboard section	16 input keys (0~F)
Volume control	Controls output volume
Speech output power	1W (Max)
Line output	Output before and after filtering
Speaker	12cm single cone, 8 Ω
EPROM	M5L2716K or M5L2732K (the EPROM may be removed from the PC7000 by means of an access window)
External switches	(1) Male/female speaker switch (2) Low-high bit rate switch (3) 2716/2732 EPROM switch

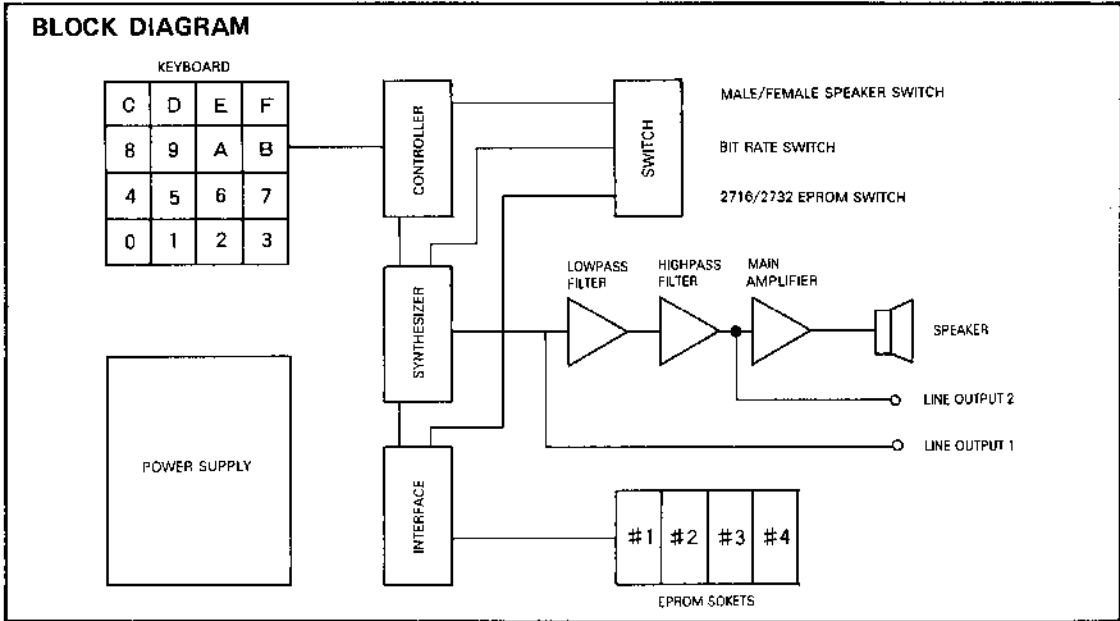

SPEECH SYNTHESIS EVALUATION UNIT

SOFTWARE

The PC7000 has a configuration similar to the PCA7002 single-board computer, and uses the same M5L8049-005P CPU as does the PCA7002. On the PCA7002, corresponding to the speech input to the 18 ports, speech is generated in accordance with speech sequences and speech addresses previously recorded in EPROM, whereas in the PC7000, of the 18 ports 1 through 16 correspond to the keyboard

inputs 0 through F. Therefore, it is necessary to store in the PC7000 EPROM addresses 0000₁₆ through 007F₁₆ voice sequences which correspond to the keyboard 0 through F.

For details of the method of writing voice sequence data and starting addresses, refer to the manual for the PCA7002.

MITSUBISHI MICROCOMPUTERS PC8500, PCA8503

MELCS 85/1 PORTABLE MICROCOMPUTER CONSOLE

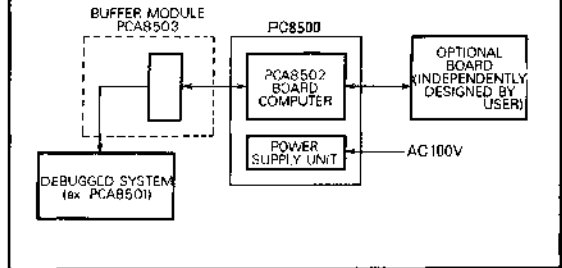

DESCRIPTION

The PC8500 portable microcomputer console is a microcomputer system embodying the PCA8502 board computer. Not only it does operate as a general-purpose microcomputer, but it also can be used as a debugging system, in which the M5L8085AP MELPS 85 8-bit microprocessor (identical with Intel's 8085A) is used. The PCA8503 is a buffer module that interfaces the debugged system with the PC8500 through an IC socket of the M5L8085AP, S, when the PC8500 is used as a debugging system.

FEATURES

- Can be used as a debugging system in which a microprocessor identical with the M5L8085AP is used.
- Interfacing of the PC8500 with the debugged system through an IC socket of the microprocessor on the debugging system.
- The PCA8503 is provided for the interface.
- Feasible to use the PC8500 as a customized unit by adding an optional board to the general-purpose microcomputer PC8500.
- The 24-key keyboard and the eight 7-segment LED display are furnished as input/output devices.
- Contains a circuit for a system typewriter on the board.
- The PC8500 is housed in a portable carrying case.

MELCS 85/1 SYSTEM CONFIGURATION

APPLICATIONS

- Debugging unit
Hardware and software development of a system in which an 8-bit microprocessor identical with the M5L8085A is used.
Testing for board computer.
Maintenance and inspection systems that use a board computer.
- General-purpose microcomputer
Application system that is customized by the user (e.g. PROM writer, data logger, board checking system, etc).

MELCS 85/1 PORTABLE MICROCOMPUTER CONSOLE

FUNCTION

The PC8500 is composed of the board computer PCA8502 and the power supply unit, as shown in the block diagram. The functions of the PCA8502 comprise the following hardware functional blocks:

- (1) CPU
- (2) Program memory
- (3) RAM
- (4) Keyboard display interface
- (5) Parallel I/O interface
- (6) Serial I/O interface
- (7) Special logical circuit designed for the debugging system

The PCA8502 offers 1K bytes of EPROM and 4K bytes of RAM and also releases the M5L 8255AP PPI (8-bit × 3 programmable I/O ports) for a parallel I/O interface.

Program monitoring is provided by a monitor that controls the keyboard and the LED display of the PCA8502 and a monitor that controls the system typewriter

The PCA8503 is a buffer module employed in interfacing the PC8500 (PCA8502) with a user system (debugged board), as shown in the block diagram, and supplied as an optional board.

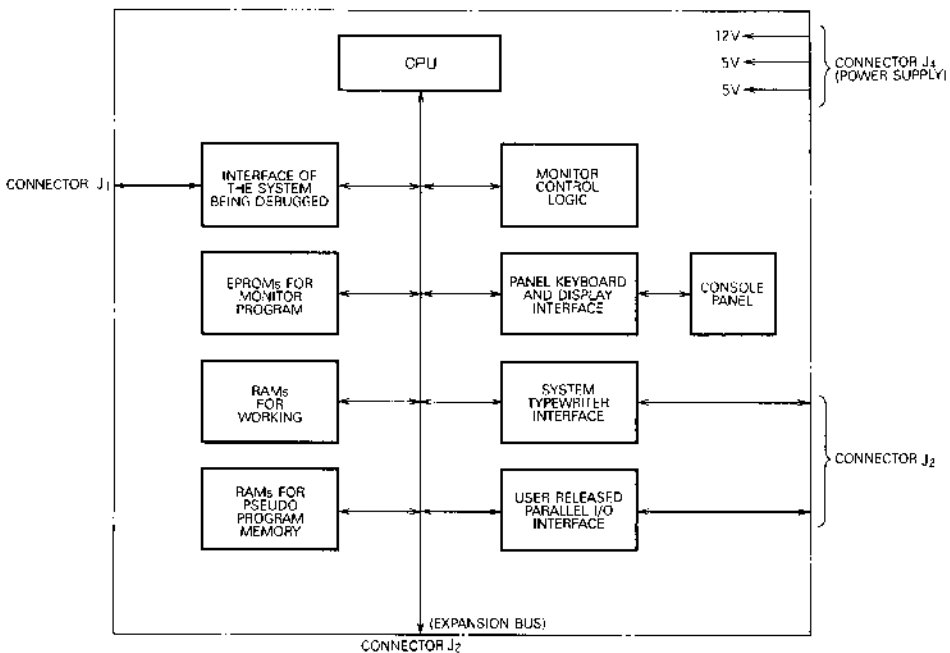

BLOCK DIAGRAMS
PC8500

PCA8503

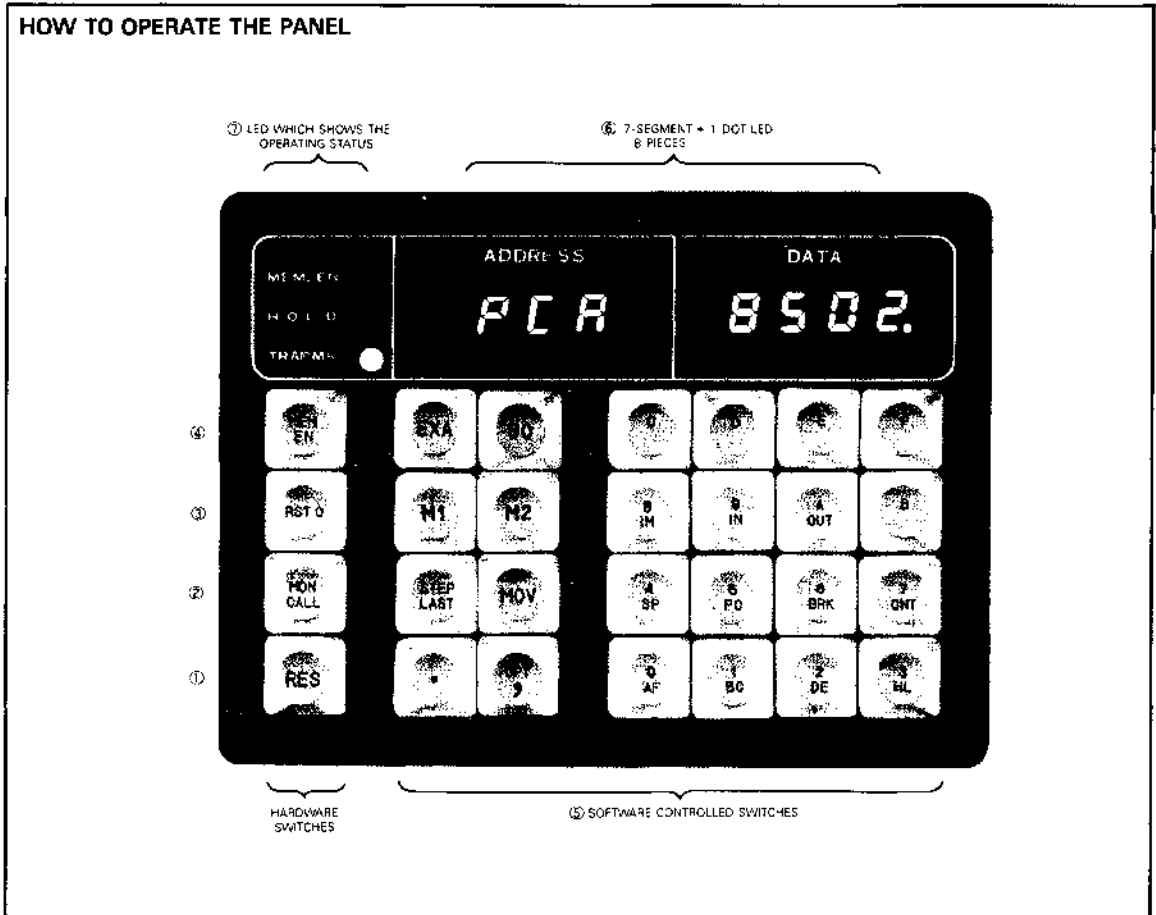

PCA8502 BLOCK DIAGRAM

MELCS 85/1 PORTABLE MICROCOMPUTER CONSOLE

HOW TO OPERATE THE PANEL

1 RES (RESET)

Resets the I/O controllers of the system, including the CPU, and the CPU enters the WAIT state.

2 MON CALL (MONITOR CALL)

With this switch, the control of the CPU is removed to the monitor area. As this switch was depressed following the depression of the "RES" switch, the CPU enters the monitor command request state after executing the monitor program.

3 RST 0 (RESTART 0)

As this switch was depressed after depressing the "RES" switch, it makes the CPU perform from the address 0₁₆.

4 MEN EN (MEMORY ENABLE)

Depression of this switch enables the pseudo program memory, and the RAM address provided in the system is changed to the area of 0000₁₆~0FFF₁₆ superseding the ROM area. While it is disabled, it can be used as an ordinary RAM that will have addresses designated by the mini-switches provided in the system.

5 Software control keyboard

This keyboard consists of 24 2-key rollover scanning keys, and is used for entering commands for the monitor program. It can also serve as a user-specified input device, when a user's program is prepared for it.

6 7-segment LED display

It is composed of 8 pieces of 7-segment LEDs and used as an output device for the monitor. It can also serve as a user-specified output device when a user's program is prepared for it.

7 Status indicating LEDs

The MEN EN indicator LED displays the state of the pseudo program memory; it indicates that the pseudo program is enabled when the LED is on.

The HOLD indicator LED shows that the CPU is in the HOLD state.

The TRAPMK indicator LED lights to show that the TRAP interrupt signal is being masked. It remains lit as long as the monitor program is in execution or the command designating TRAP interrupt is valid.

User released I/O port	8-bit × 3 I/O programmable ports	
Functions as a debugging system	Applicable CPU	M5L8085AP (identical with Intel's 8085A)
	CPU clock	Can be operated with clock from the user's system (3.125MHz max)
	Interface with user system	To be connected with the IC socket of the CPU of user's system through the buffer module (PCA8503)
	User's address area	All the address areas except those below, which must be used by the debugging unit, are released to users. Address area: F000 ₁₆ ~ FFFF ₁₆ I/O address area: F0 ₁₆ ~ FF ₁₆
	Interrupt	All interrupt signals to the CPU are released for users. As for TRAP interrupt, it is possible to mask it by the monitor command
Pseudo program memory	It is possible to substitute the address area 0000 ₁₆ ~ 0FFF ₁₆ of the user's system with the RAM in the debugging system.	

Item	Description
System monitor	<p>As a system monitor, there are two types of monitors: the keyboard monitor, which uses the keyboard and the LED display as I/O device, and a TTY monitor, which uses the system typewriter as I/O device</p> <p>Functions of the monitor are:</p> <ol style="list-style-type: none"> (1) Verifying the contents of the memory (2) Verifying registers of the CPU (3) Execution of user's program (4) Executing a program after setting breakpoint address (5) Step-by-step execution of program (6) Verifying I/O registers (7) Block transferring of data (8) Setting and resetting interrupt mask (9) Data dump and load to the memory (hexadecimal notation is available in the case of the TTY monitor)
Optional board	Available for expansion of the CPU bus A single optional board (approx. 140 × 310mm) can be added.
Connectors	<p>J1 (50 pins): for the interface with the user's system J2 (50 pins): for the parallel I/O port and the system typewriter interface J3 (40 pins): for CPU bus J4 (10 pins): for power supply connection</p>
Power supply	5V, 2.5A (typ) 12V, 150mA (typ) -5V, 90mA (typ)
Dimensions	(W × L × H): 310 × 300 × 22mm

SPECIFICATIONS OF THE PCA8503

Item	Description
Function	Interfaces the board computer PCA8502 with a user's system which has a CPU identical to the M5L8085A. Furnished with the driver/receiver and an extension cable.
Connectors	50 pins and 40 pins
Power supply	Supplied from the PCA8502, 5V/350mA (typ)
Cable	Approx. 1m long
Dimensions	(W × L × H): 120 × 100 × 25mm
Operating free-air temperature	0 ~ 50°C

SPECIFICATIONS OF THE PC8500

Item	Description
Function	In compliance with function of the PCA8502 implemented
Supply power input	AC100V±10%, 50Hz/60Hz
Internal supply power	5V/5A, 12V/300mA, -5V/300mA Those used in the board are 5V/2.5A, 12V/150mA, -5V/90mA (typ).
Operating free-air temperature	10 ~ 40°C
Dimensions (carrying case)	(W × L × H): 370 × 350 × 140mm
Weight	7kg

MELCS 85/1 PORTABLE MICROCOMPUTER CONSOLE

SYSTEM ADDRESS AREAS

Among the address areas used by the system, the memory addresses $0000_{16} \sim EFFF_{16}$ and the I/O device addresses $00_{16} \sim EF_{16}$ are all released for the user, and the rest of the areas are used by the system. So the user should stay within the prescribed areas.

Furthermore, the RAM area released for the user may be switched over of its address in the unit of 4K bytes using the mini-switches.

PSEUDO PROGRAM MEMORY

Among the address areas in the user's system, it is possible to substitute the area $0000_{16} \sim OFFF_{16}$ with the RAM within the system.

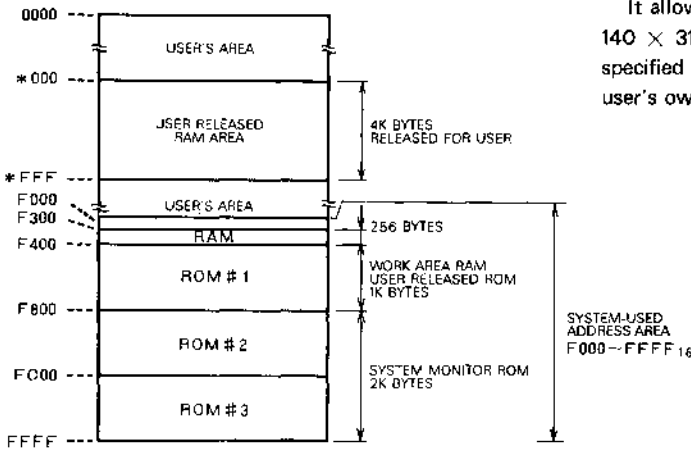

Substitution is enabled by depressing the MEM
EN key, which allows the RAM to access the area $0000_{16} \sim OFFF_{16}$, enabling the execution of a user's program, and altering the contents of the RAM.

OPTIONAL BOARD

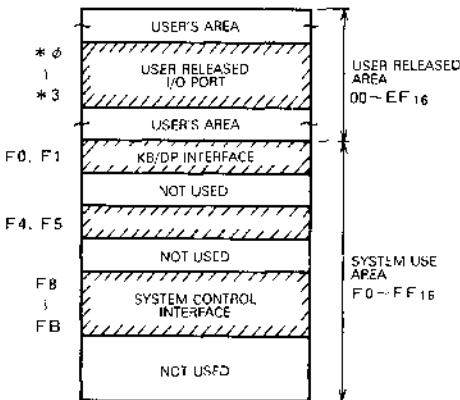

It allows expansion of the system as the bus lines of the CPU are extended to the connector J₃.

It allows addition of one extra board whose size is about 140×310 mm as an optional board with which a user-specified device may be obtained by preparing it with the user's own design.

CROSS ASSEMBLER MACHINE

DESCRIPTION

The PC9000 is a cross assembler machine. It is capable of converting programs for the Mitsubishi single-chip microcomputers written in assembler language to machine language. In addition, it can perform such debugging functions as disassembly and act as an EPROM writer.

FEATURES

- Input of the source program from the keyboard
- An efficient screen editor allows editing of source programs
- Program dump and load to the mini-floppy disk
- Object data write/read for 2708, 2716 and 2732 EPROM devices
- Listing using a Centronix-compatible printer is possible
- Data transmission is possible to the PC4000 debugging machine
- Usable with all types of Mitsubishi single-chip microcomputers
- Compact, desk-top design

APPLICATION

Software development support for Mitsubishi single-chip microcomputers.

FUNCTION

The PC9000 as shown in the configuration diagram consists of the following hardware

- (1) Control CPU and bootstrap ROM
- (2) 48K byte RAM
- (3) 2K byte display screen RAM
- (4) 9-inch CRT display circuit
- (5) EPROM writer circuit
- (6) ASCII keyboard
- (7) Hardcopy output by means of an internal mini-printer circuit or an external printer interface circuit
- (8) Floppy disk controller (two mini floppy disk drives)
- (9) Parallel input/output interface circuit (two lines)
- (10) Power supply

An M5L8085AP is used as the control CPU. The keyboard, CRT, mini-floppy disk drives, and printer interfaces are connected by means of a bus line. The keyboard is used for input of commands to the monitor and source program data verification. The 9-inch green CRT display screen is capable of displaying 24 lines of 80 characters. As a printer a 20 column mini-printer is built-in to the PC9000 in addition to the ability to use an 80 column printer having Centronix compatibility via an interface which is available. The built-in mini-printer may be used to output

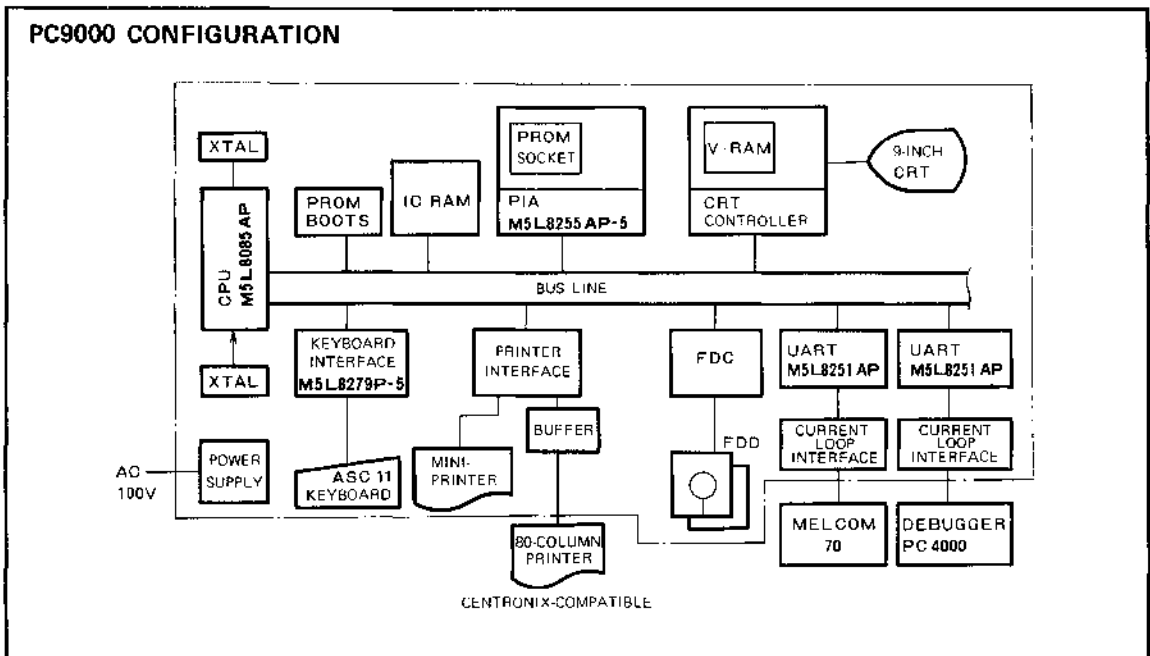

CROSS ASSEMBLER MACHINE

the disassembly results while the external printer may be used to output the assembly listing as well as disassembly listing.

FUNCTIONAL DESCRIPTION

The PC9000 contains the assembler, disassembler, source editor, and EPROM writer functions required for software support of microcomputers. These functions are summarized in the Table.

Function	Effect:	Applicable devices
Assemble	Source input: keyboard output: printer, EPROM, data transfer (with debugging unit)	All 4-bit single-chip PMOS, and CMOS microcomputers M5L8048, M5L8049 and M5L8041A 8-bit single-chip microcomputers
Disassemble	Disassembly of the specified file Output: 20 column printer, external printer	Same as above
Source editor	Deletion, insertion, modification, character search, and screen editing	Same as above
PROM writer	EPROM erase check, write, verification, read	M5L2708K, M5L2716K, M5L2732K

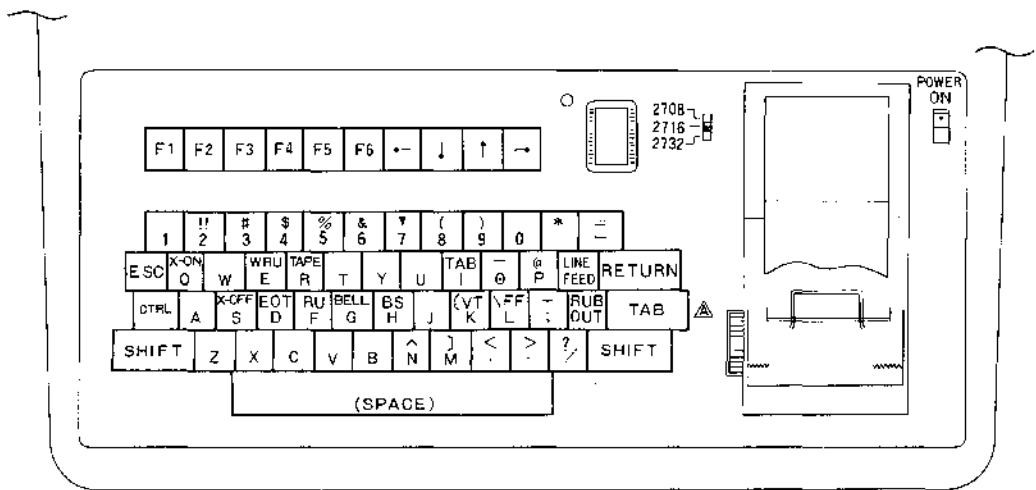

CROSS ASSEMBLER MACHINE

SPECIFICATIONS

Item	Specification
Structure	Desktop-type, single cabinet
C P U	Mitsubishi M5L8085AP (2.45 MHz clock)
IC memory	2K byte ROM (bootstrap area), 48K-byte DRAM, 2K-byte VRAM
Memory device	Mini floppy disk x 2 drives, double-sided, double-density
Display	9-inch green CRT display, 80 lines x 25 characters
Keyboard	Modified ASCII specifications, 2-key lockout
Dedicated printer	5 x 7 dot Matrix thermal printer, 20 columns, 2 lines/s. Paper width: 60mm.
Printer interface	Centronix, parallel interface Interface connector: 36-pin DDK Amphenol
Serial input/output interface	20mA current loop (2 lines)
Data transfer format	MELPS 85 Hexadecimal (equivalent to Intel Hexadecimal)
Applicable microcomputers	MELPS 8-48 (M5L8048-XXXXP, M5L8049-XXXXP and others) MELPS 4 (M58840-XXXXP and others) MELPS 41 (M58494-XXXXP) MELPS 42 (M58496-XXXXP and others)
Outer dimensions and weight	Desk top type 470(W) x 290(H) x 490(D), 17kg
Power supply	AC 100V ± 10% 50/60Hz

KEYBOARD ARRANGEMENT

MITSUBISHI MICROCOMPUTERS PCA4001

MELPS 4 DEDICATED BOARD

DESCRIPTION

The dedicated MELPS 4 PCA4001 board is for use with the PC4000 debugging machine for the M58840-XXXP and M58841-XXXSP single-chip 4-bit microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's systems by a flat cable
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware, and software for systems using the MELPS 4 (M58840-XXXP, M58841-XXXSP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4001 consists of the following hardware:

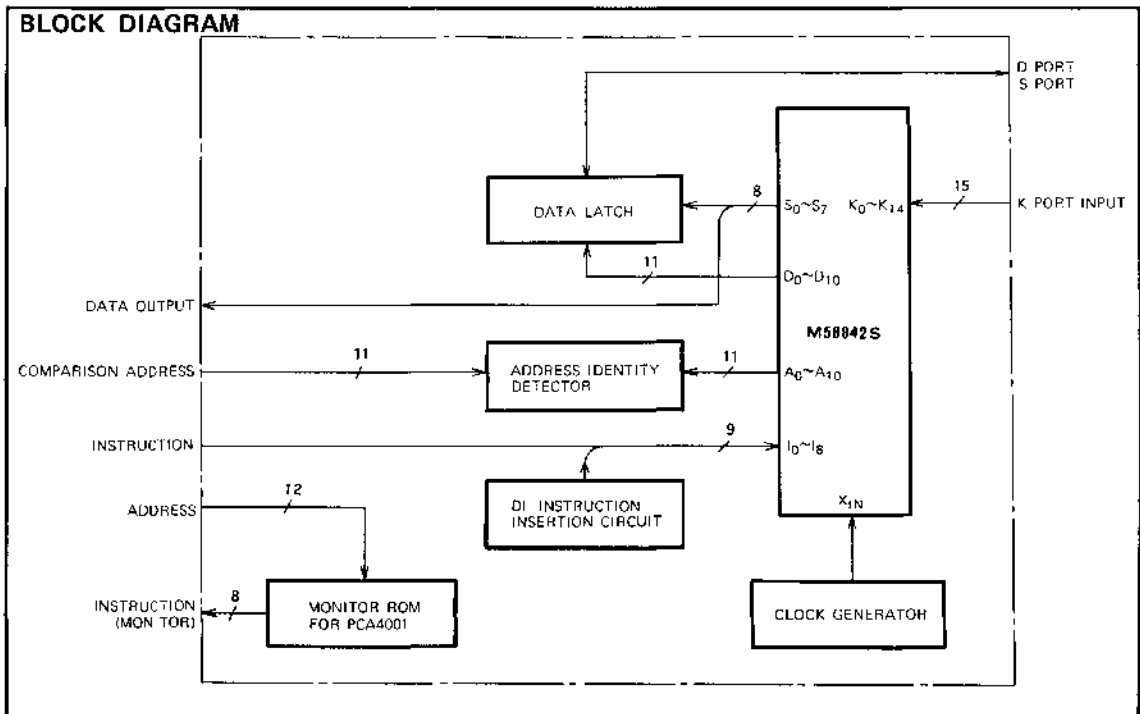

- (1) Evaluation chip (M58842S) and peripheral circuitry
- (2) EPROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The board and the user's systems can be connected by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for MELPS 4 microcomputers using the monitor program contents of a ROM mounted on the dedicated board. The evaluation chip (M58842S) loaded on the board executes program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item		Specification
Applicable micro-computers		M58840-XXXXP, M58841-XXXXSP
Clock frequency	Package	600kHz
	Variable range	300 ~ 600kHz
Applicable debugging machine		PC4000 (connected by a cartridge connector)
Power supply		Supplied by the PC4000
Connection to user's systems		By an accessory cable
Debugging functions (contents of monitor EPROM)		<ul style="list-style-type: none"> • Program execution from any address and halt • Single-step operation • Data writing to EPROM and reading • Confirmation and change of the contents of program RAM • Serial data transfer to an external device • Confirmation and change of the RAM in the evaluation chip and the contents of the following registers and flags • Program counter • Data pointer • Accumulator • B register • H/L registers

MITSUBISHI MICROCOMPUTERS PCA4003

MELPS 4 DEDICATED BOARD

DESCRIPTION

The PCA4003 is a dedicated MELPS 4 board for use with the PC4000 debugging machine for the M58843-XXXXP 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by a flat cable
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware and software for systems using the MELPS 4 (M58843-XXXXP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4003 consists of the following hardware.

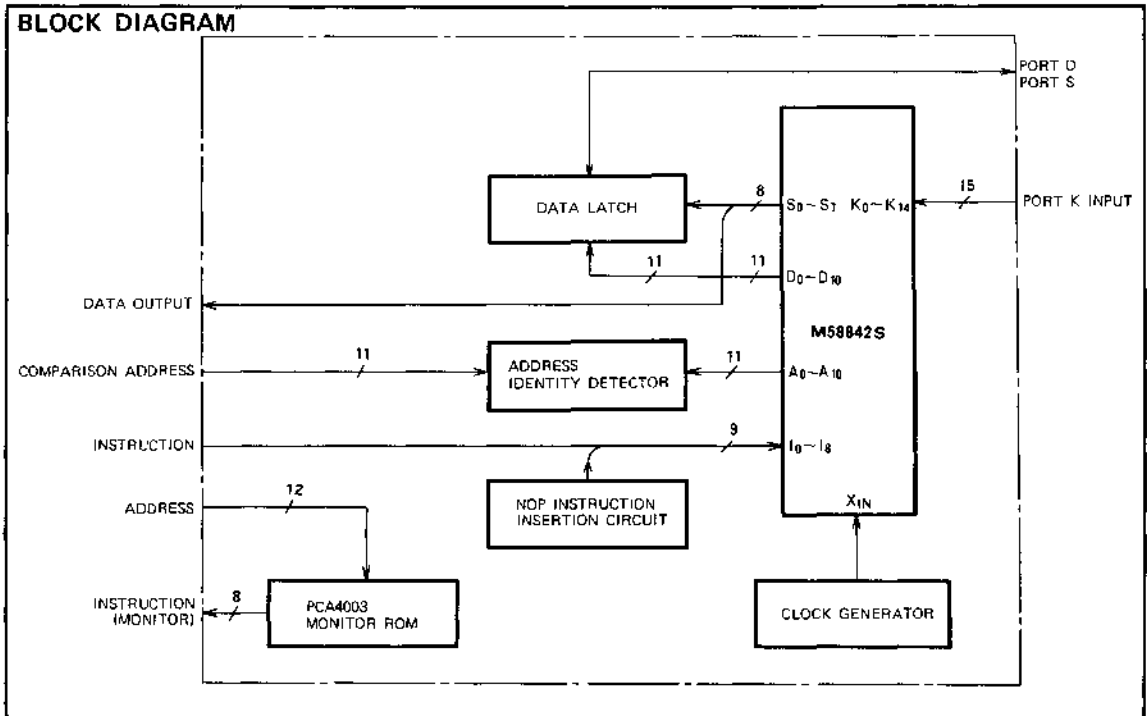

- (1) Evaluation chip (M58842S) and peripheral circuitry
- (2) EPROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The board and user system can be connected by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for MELPS 4 microcomputers using the monitor program contents of a ROM mounted on the dedicated board. The evaluation chip (M58842S) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item		Specification
Applicable microcomputers		M58843-XXXXP
Clock frequency	Package	455 kHz
	Variable range	300 - 600 kHz
Applicable debugging machine		PC4000 (connected by a card edge connector)
Power supply		Supplied by the PC4000
Connection to user's system		By an accessory cable
Debugging functions (contents of monitor, EPROM)		<ul style="list-style-type: none"> ● Program execution from any address and halt ● Single-step operation ● Data writing to EPROM and reading ● Confirmation and change of the contents of program RAM ● Serial data transfer to an external device ● Confirmation and modification of the RAM data in the evaluation chip and verification and modification of the following registers and flags: <ul style="list-style-type: none"> ● Program counter ● Data pointer ● Accumulator ● B register ● H/L registers

MITSUBISHI MICROCOMPUTERS PCA4004

MELPS 4 DEDICATED BOARD

DESCRIPTION

The PCA4004 is a dedicated MELPS 4 board for use with the PC4000 debugging machine for the M58844-XXXSP 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by a flat cable
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware and software for system using the MELPS 4(M58844-XXXSP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4004 consists of the following hardware.

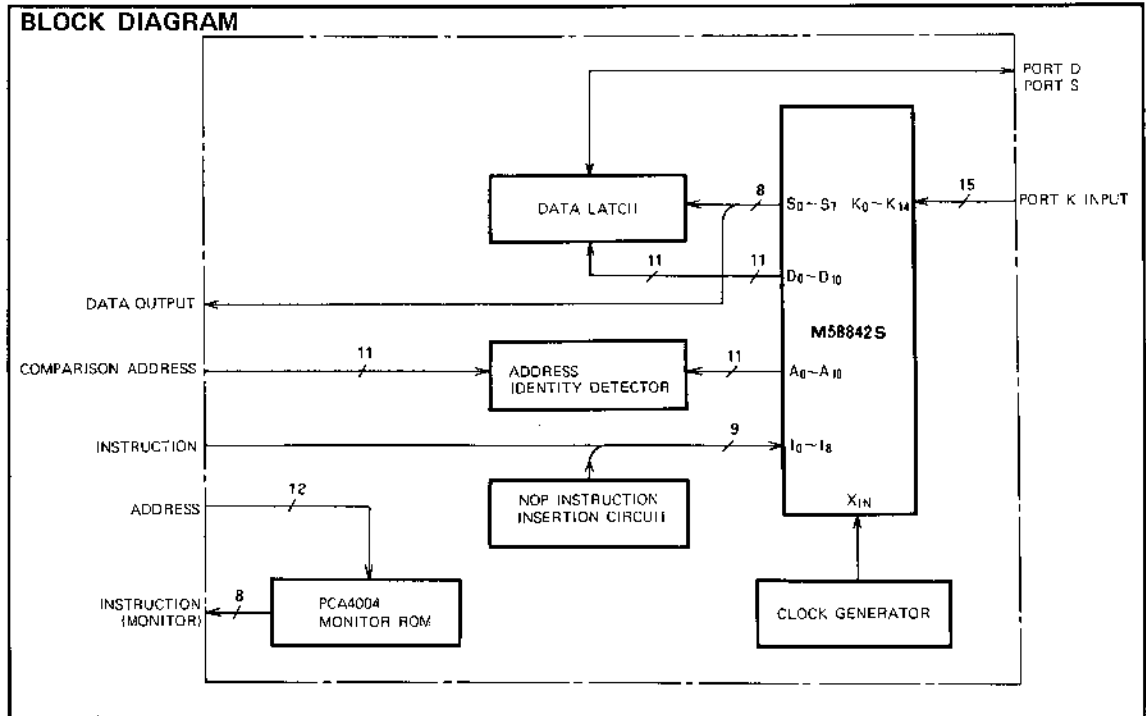

- (1) Evaluation chip (M58842S) and peripheral circuitry
- (2) EPROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The board and user system can be connected by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for MELPS 4 microcomputers using the monitor program contents of a ROM mounted on the dedicated board. The evaluation chip (M58842S) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item		Specification
Applicable microcomputers		M58844-XXXSP
Clock frequency	Package	455 kHz
	Variable range	300 - 600 kHz
Applicable debugging machine		PC4000 (connected by a card edge connector)

MITSUBISHI MICROCOMPUTERS PCA4005

MELPS 4 DEDICATED BOARD

DESCRIPTION

The PCA4005 is a dedicated MELPS 4 board for use with the PC4000 debugging machine for the M58845-XXXSP 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by a flat cable
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware and software for systems using the MELPS 4 (M58845-XXXSP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4005 consists of the following hardware.

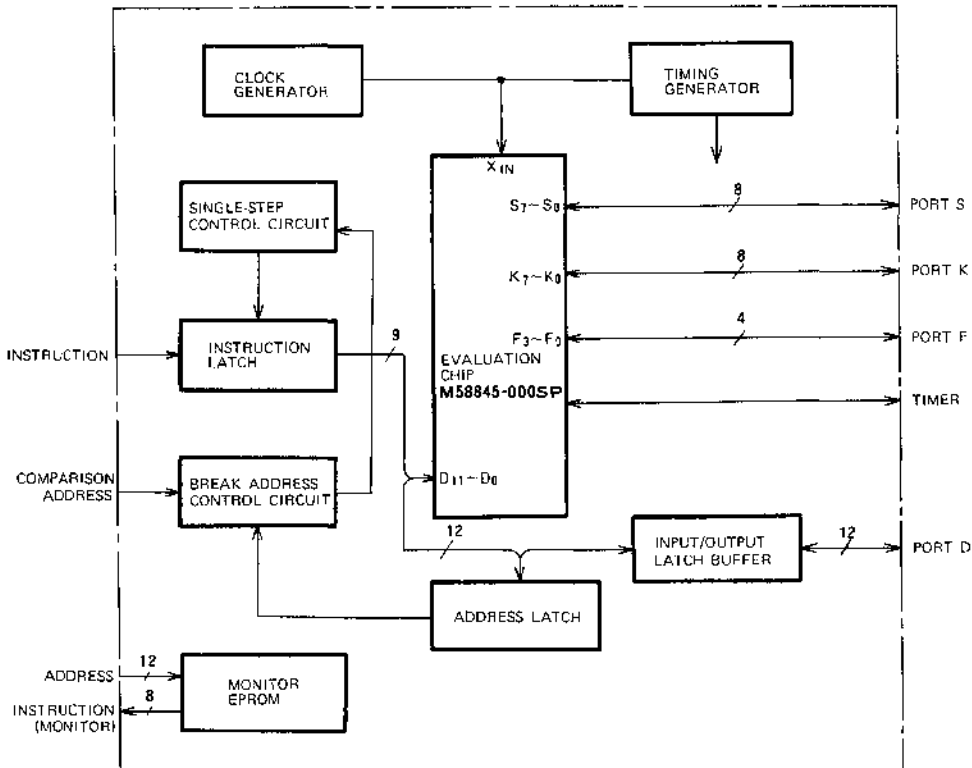

- (1) Evaluation chip (M58845-000SP) and peripheral circuitry
- (2) EPROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The PC4000 is connected to this board using a card edge connector and this board is connected to the user system by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for the M58845-XXXSP using the contents of the monitor ROM mounted on the dedicated board. The evaluation chip (M58845-000SP) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

MITSUBISHI MICROCOMPUTERS PCA4011

MELPS 41 DEDICATED BOARD

DESCRIPTION

The PCA4011 is a dedicated MELPS 41 board for use with the PC4000 debugging machine for the M58494-XXXP 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by a flat cable
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware and software for systems using the MELPS 41 (M58494-XXXP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4011 consists of the following hardware:

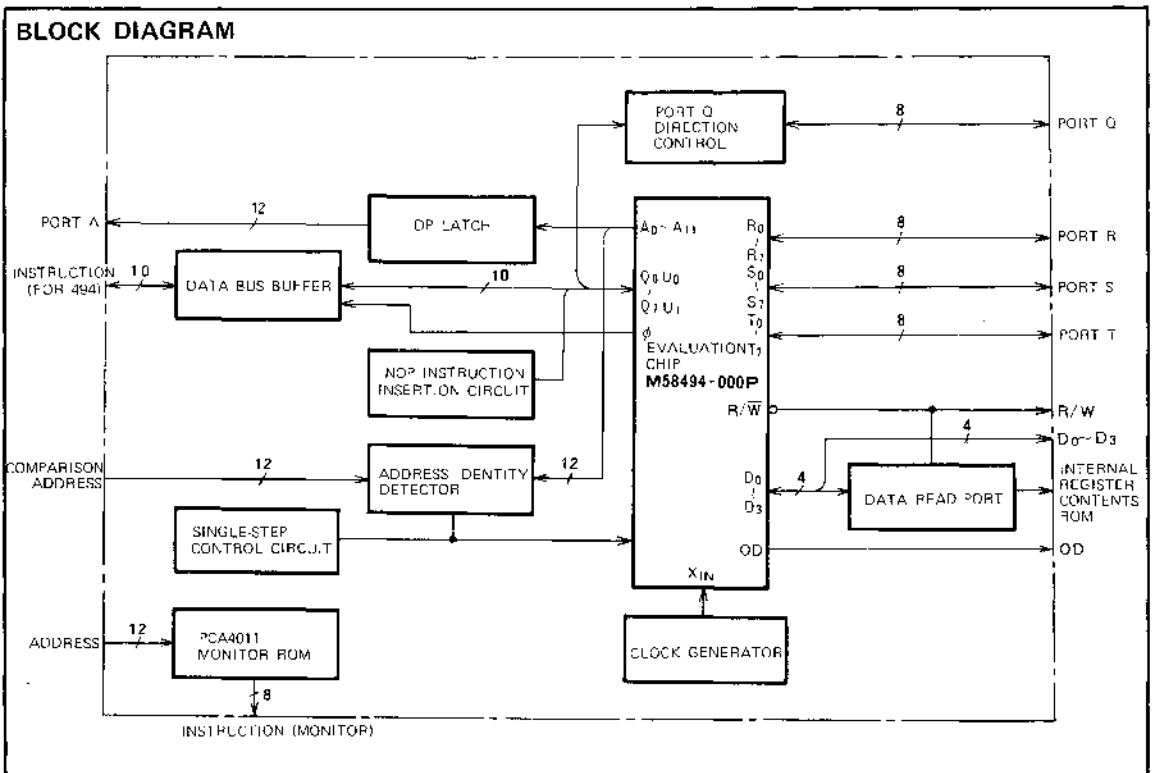

- (1) Evaluation chip (M58494-000P) and peripheral circuitry
- (2) ROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The PC4000 is connected to this board using a card edge connector and this board is connected to the user system by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for the MELPS 41 using the contents of the monitor ROM mounted on the dedicated board. The evaluation chip (M58494-000P) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item		Specification
Applicable microcomputers		M58494 - XXXP
Clock frequency	Package	250kHz
	Variable range	100 - 350kHz (externally connected)
Applicable debugging machine		PC4000 (connected by a card edge connector)
Power supply		Supplied by the PC4000
Connection to user's system		By an accessory cable
Debugging functions (contents of monitor EPROM)		<ul style="list-style-type: none"> ● Program execution from any address and halt ● Data writing to EPROM and reading ● Confirmation and change of the contents of program RAM ● Serial data transfer to an external device ● Confirmation and modification of the RAM data in the evaluation chip (M58494-000P) and the contents of the following registers and flags: <ul style="list-style-type: none"> ● Program counter ● S register ● Data pointer ● T register ● Stack pointer ● CY flag ● Accumulator ● B register ● O register ● R register

MITSUBISHI MICROCOMPUTERS PCA4012

MELPS 42 DEDICATED BOARD

DESCRIPTION

The PCA4012 is a dedicated MELPS 42 board for use with the PC4000 debugging machine for the M58496-XXXXP 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by flat cables
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks

APPLICATIONS

The development of hardware and software for systems using the MELPS 42 (M58496-XXXXP) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4012 consists of the following hardware:

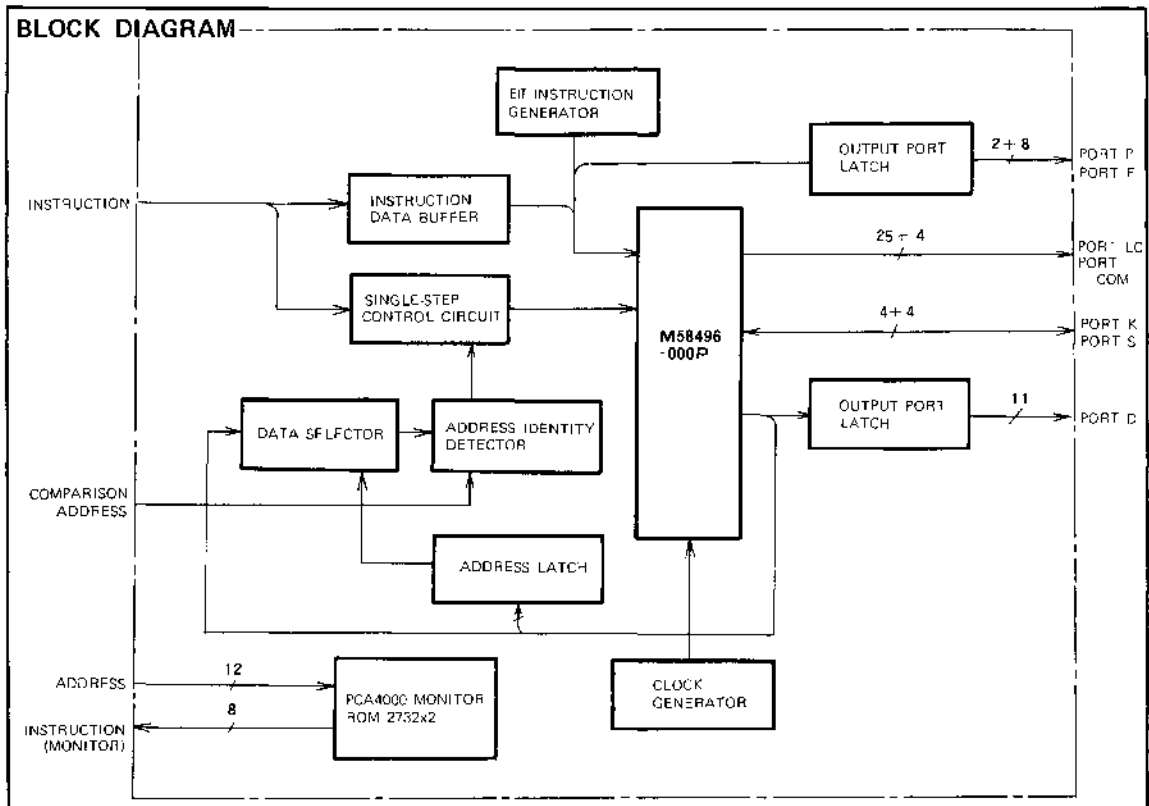

- (1) Evaluation chip (M58496-000P) and peripheral circuitry
- (2) ROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The PC4000 is connected to this board using a card edge connector and this board is connected to the user system by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for the MELPS 42 using the contents of the monitor ROM mounted on the dedicated board. The evaluation chip (M58496-000P) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item	Specification
Applicable microcomputers	M58496-XXXXP
Clock frequency	Package 4.194304MHz
	Variable range 2 ~ 4.2MHz
Applicable debugging machine	PC4000 (connected by a card edge connector)
Power supply	Supplied from the PC4000 when inserted into the debugging machine
Connection to user's system	By an accessory cable
Debugging functions (contents of monitor) (FPROV)	<ul style="list-style-type: none"> ● Program execution from any address and halt ● Single-step operation ● Data writing to EPROM and reading ● Confirmation and change of the contents of program RAM ● Serial data transfer to an external device ● Confirmation and change of the RAM in the evaluation chip (M58496-XXXXP) and the contents of the following registers and flags ● Data pointer ● Accumulator ● B register ● CY flag

MITSUBISHI MICROCOMPUTERS PCA4014

MELPS 42 DEDICATED BOARD

DESCRIPTION

The PCA4014 is a dedicated MELPS 42 board for use with the PC4000 debugging machine for the M58497-XXXX 4-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by flat cables.
- Single-step operation and breakpoint operation capability from the PC4000 debugging machine keyboard. Debugging functions such as confirmation of internal register contents.
- Can be used with external and internal clocks.

APPLICATIONS

The development of hardware and software for systems using the MELPS 42 (M58497-XXXX) single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA-4014 consists of the following hardware:

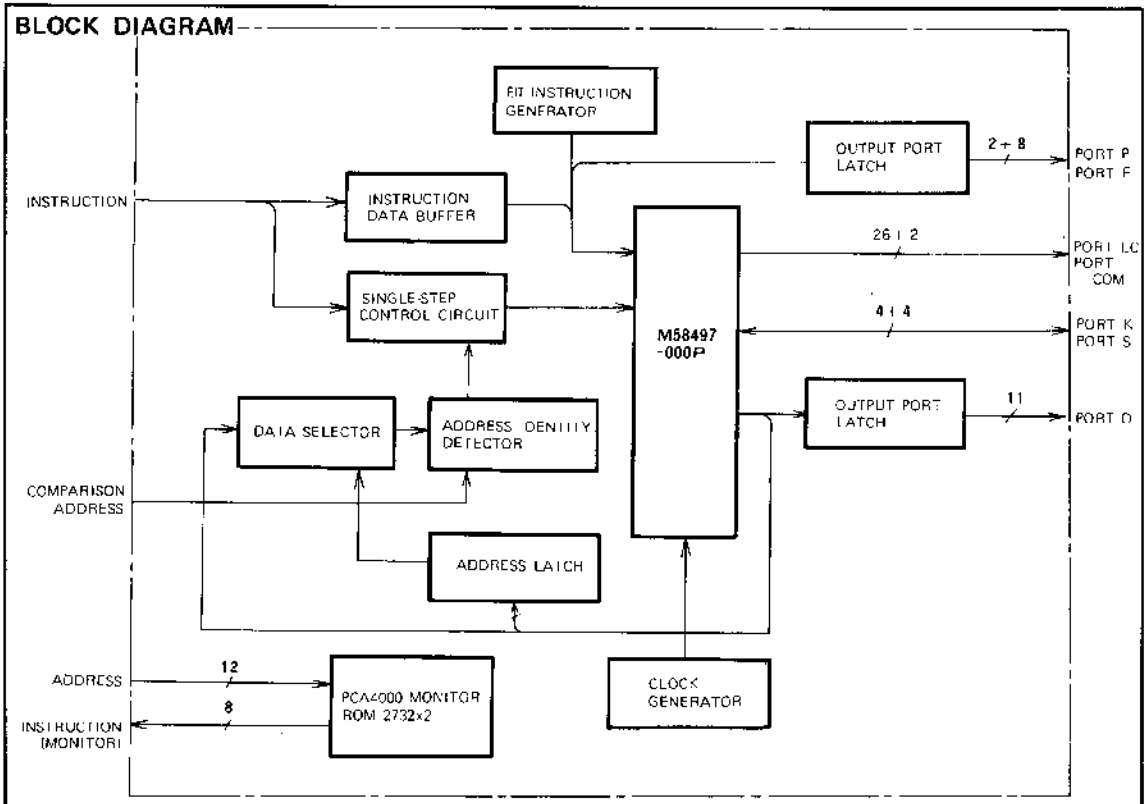

- (1) Evaluation chip (M58497-000P) and peripheral circuitry
- (2) EPROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

The PC4000 is connected to this board using a card edge connector and this board is connected to the user system by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for the MELPS 42 using the contents of the monitor ROM mounted on the dedicated board. The evaluation chip (M58497-000P) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

SPECIFICATIONS

Item		Specification
Applicable microcomputers		M58497-XXXXP
Clock frequency	Package	480KHz
	Variable range	2 ~ 4.2MHz / 32KHz
Applicable debugging machine		PC4000 (connected by a card edge connector)
Power supply		Supplied from the PC4000 when inserted into the debugging machine.
Connector to user's system		By an accessory cable
Debugging functions (contents of monitor EPROM)		<ul style="list-style-type: none"> ● Program execution from any address and halt ● Single-step operation ● Data writing to EPROM and reading ● Confirmation and change of the contents of program RAM ● Serial data transfer to an external device ● Confirmation and change of the RAM in the evaluation chip (M58497-300P) and the contents of the following registers and flags: <ul style="list-style-type: none"> ● Data pointer ● Accumulator ● B register ● CY flag

MITSUBISHI MICROCOMPUTERS PCA8400

MELPS 8-48 DEDICATED BOARD

DESCRIPTION

The PCA8400 is a dedicated MELPS 8-48 board for use with the PC4000 debugging machine for the 8-bit single-chip microcomputers and is used by inserting the board in the PC4000 cabinet.

FEATURES

- Connection to user's system by means of a 40-pin DIL plug
- Control circuits and connectors for the M5L8748S writing adaptor (PC4100)

APPLICATIONS

The development of hardware and software for systems using the MELPS 8-48 8-bit single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA8400 consists of the following hardware:

- (1) Evaluation chip (M5L8039P-6) and peripheral circuitry
- (2) ROM with the PC4000 monitor program
- (3) Single-step and breakpoint control circuit
- (4) Program memory interface circuit
- (5) Input/output buffer/latch circuit

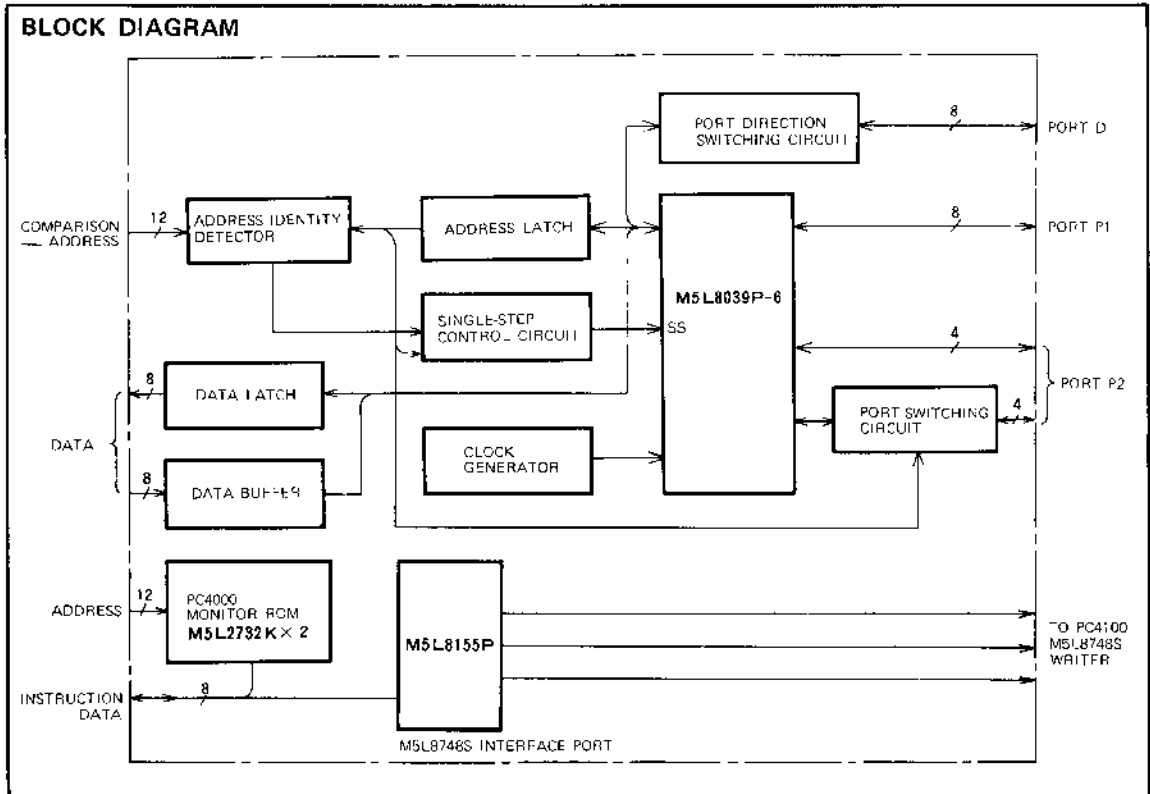

The PC4000 is connected to this board using a card edge connector and this board is connected to the user system by means of an accessory cable.

FUNCTION

The debugging machine PC4000 operates as a debugging machine for the MELPS 8-48 using the contents of the monitor ROM mounted on the dedicated board. The evaluation chip (M5L8039P-6) loaded on the board executes the program stored in the program memory in the PC4000 debugging machine.

The internal status of the evaluation chip is read out under monitor CPU control when single-step operation and breakpoint operation are halted.

An interface and connector to enable connection to the M5L8748S writing adaptor PC4100 has been provided, allowing programs to be written and read from the M5L8748S.

SPECIFICATIONS

Item		Specification
Applicable microcomputers		M5L8048-XXXXP M5L8049-XXXXP M5L8748S (PC4100) M5L8039P-6
Clock frequency	Package	6.144MHz
	Variable range	1 ~ 6.144MHz (By changing the oscillator crystal)
Applicable debugging machine	PC4000 (connected by a card edge connector)	
Power supply	Supplied from the PC4000 when inserted into the debugging machine	
Connection to user's system	By an accessory cable	
Debugging functions (contents of monitor EPROM)	<ul style="list-style-type: none"> ● Program execution from any address and halt ● Data writing to EPROM and reading ● Confirmation and change of the contents of program RAM ● Serial data transfer to an external device ● Confirmation and modification of the RAM data in the evaluation chip (M5L8039P-6) and the contents of the following registers and flags: <ul style="list-style-type: none"> ● Program counter ● Accumulator ● PSW 	
Other	By connecting the PC4000, read and write operations to the M5L8748S can be performed.	

MITSUBISHI MICROCOMPUTERS PC4100

M5L8748S PROGRAMMING ADAPTOR

DESCRIPTION

The PC4100 is a programming adaptor for use in writing a program developed on a MELPS 8-48 dedicated PCB400 board in a PC4000 debugging machine into the internal EPROM of the M5L8748S single-chip microcomputer.

FEATURES

- Interfaced to the PC4000 debugging machine and MELPS 8-48 board by means of a connector.
- A protective circuit prevents misinsertion of the device to be written into
- No external power supply is required

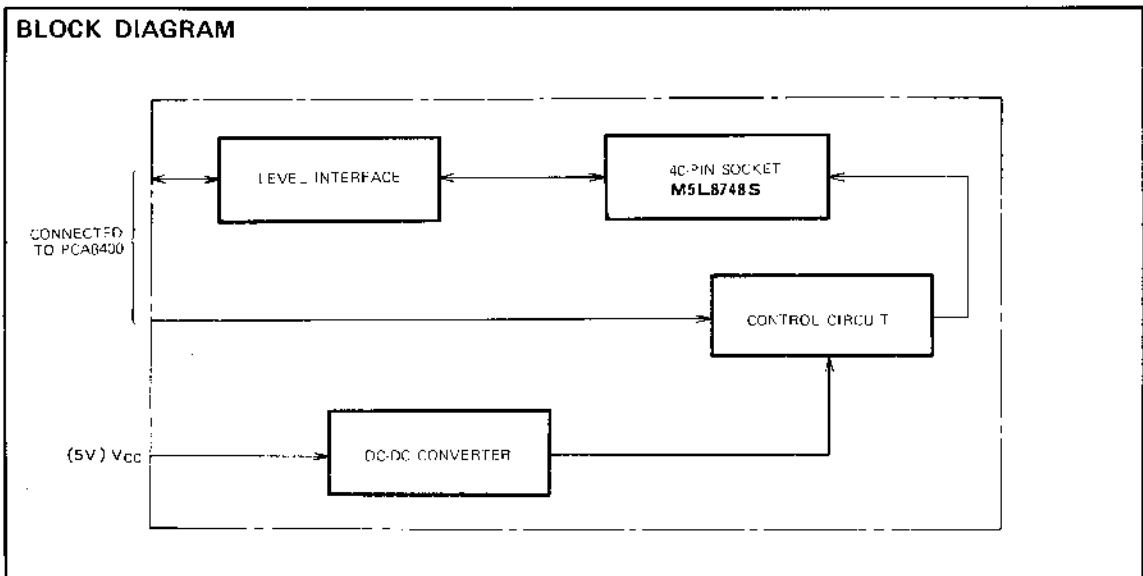

APPLICATIONS

Data writing into the M5L8748S

SPECIFICATIONS

Item	Specification
Applicable microcomputer	M5L8748S
Matching boards	PCB400 (MELPS 8-48 dedicated board) (Connected by a flat cable)
Power supply	Supplied from the PC4000 debugging machine when connected to the PCB400
Connector	Textool zero insertion force 40 pin socket
Misinsertion protection	Power supply is switched on and off by means of a read relay
Outer dimension	200 (L) x 130 (W) x 38 (H)mm

BLOCK DIAGRAM

MITSUBISHI MICROCOMPUTERS PCA4301

MELPS 4 EVALUATION BOARD

DESCRIPTION

The PCA4301 evaluation board is used as an evaluation board for MELPS 4 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58842S) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58840-XXXP and M58841-XXXSP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58840-XXXP and M58841-XXXSP
- Simple program modification using an EPROM
- Connection to user's system by means of a cable
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 4 4-bit single-chip microcomputers.

FUNCTIONS

The evaluation chip (M58842S) outputs the value of the program counter, and reads and executes the instruction stored in the appropriate EPROM address.

It is possible to have this board emulate the operation of a single-chip microcomputer.

CONFIGURATION

As can be seen in the block diagram, the PCA4301 consists of the following hardware.

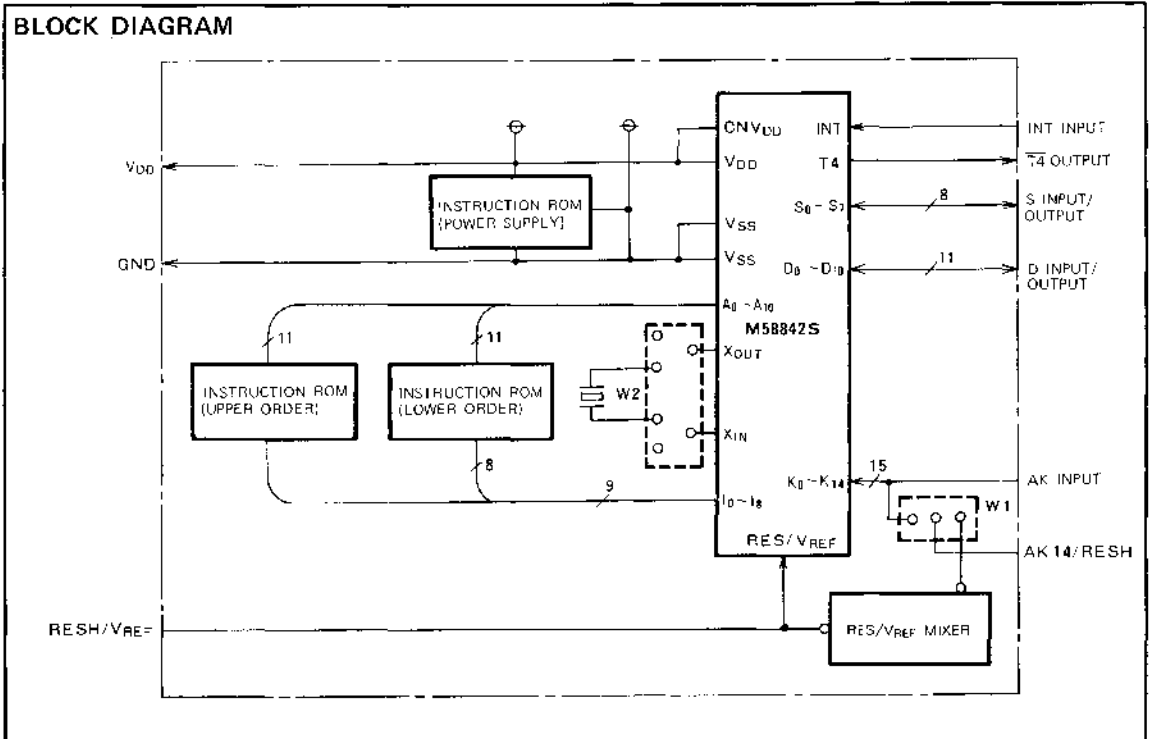

- (1) Evaluation chip and peripheral circuitry
- (2) Program EPROM socket
- (3) EPROM power supply circuit

The board and user system can be connected by means of an accessory cable.

SPECIFICATIONS

Item	Specification
Type	4-bit parallel processor
CPU	Mitsubishi Electric M58842S
Cycle time	10 μ s (when using a CF600kHz)
Memory	EPROM(H): 2K byte Upper order 1 bit (M5L2716K)
	EPROM(L): 2K byte Lower order 8 bits (M5L2716K)
Built-in clock	CF: 300 ~ 600kHz
	CF: 600kHz
Interrupts	1 level, 1 factor
Connector used	50-pin straight header
Supporting devices	PC4000 (single-chip microcomputer debugging machine) with PCA4001 (M58840-XXXP board) mounted
Power supply	<ul style="list-style-type: none"> • $-15V \pm 10\%$ (single supply) • Power supply current: 250mA (max) (during execution of a NOP instruction)
Outer dimensions	106.7 (L) x 125 (W) x 15 (H)mm

BLOCK DIAGRAM

DESCRIPTION

The PCA4303 evaluation board is used as an evaluation board for MELPS 4 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58842S) and the program EPROM (M5L2716K) possessing equivalent functions to the masked ROM M58843-XXXP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58843-XXXP
- Simple program modification using an EPROM
- Connection to user's system by means of a cable
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 4 4-bit single-chip microcomputers.

FUNCTION

The evaluation chip (M58842S) outputs the value of the program counter, and reads and executes the instruction stored in the appropriate EPROM address.

It is possible to have this board emulate the operation of a single-chip microcomputer.

CONFIGURATION

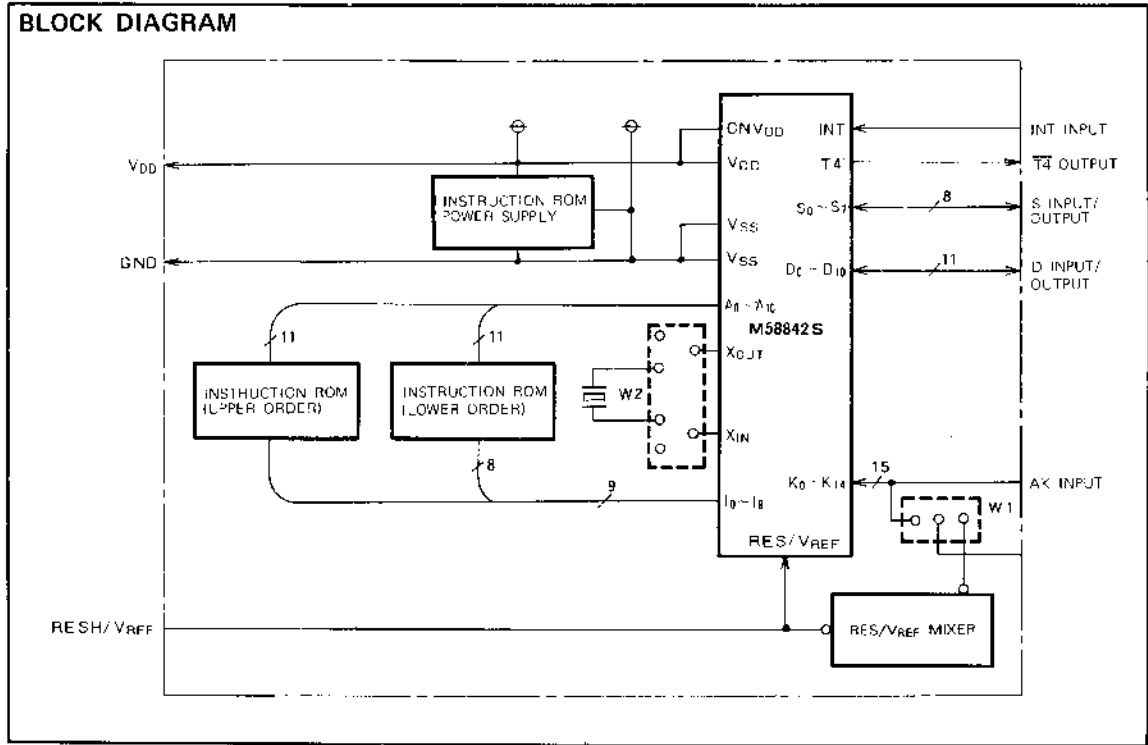

As can be seen in the block diagram, the PCA4303 consists of the following hardware.

- (1) Evaluation chip and peripheral circuitry
- (2) Program EPROM socket
- (3) EPROM power supply circuit

The board and user system can be connected by means of an accessory cable.

SPECIFICATIONS

Item	Specification	
Type	4-bit parallel processor	
CPU	Mitsubishi Electric M58842S	
Cycle time	10µs (when using a CF600kHz)	
Memory	EPROM(W1)	2K byte, Upper order 1 bit (M5L2716K)
	ERROM(I)	2K byte, Lower order 8 bits (M5L2716K)
Built-in clock	CF 300 ~ 600 kHz GF 600 kHz	
Interrupts	1 level, 1 factor	
Connector used	50-pin straight header	
Supporting devices	PC-4000 (single-chip microcomputer debugging machine) with PCA4003 (M58843-XXXP board) mounted	
Power supply	<ul style="list-style-type: none"> • $\pm 15V \pm 1\%$ (single supply) • Power supply current: 250mA (max) (during execution of NOP instruction) 	
Outer dimensions	106.7 (L) x 125 (W) x 15 (H)mm	

MITSUBISHI MICROCOMPUTERS PCA4304

MELPS 4 EVALUATION BOARD

DESCRIPTION

The PCA4304 evaluation board is used as an evaluation board for MELPS 4 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58842S) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58844-XXXSP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58844-XXXSP
- Simple program modification using an EPROM
- Connection to user's system by means of a cable
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 4 4-bit single-chip microcomputers.

FUNCTION

The evaluation chip (M58842S) outputs the value of the program counter, and reads and executes the instruction stored in the appropriate EPROM address.

It is possible to have this board emulate the operation of a single-chip microcomputer.

CONFIGURATION

As can be seen in the block diagram, the PCA4304 consists of the following hardware.

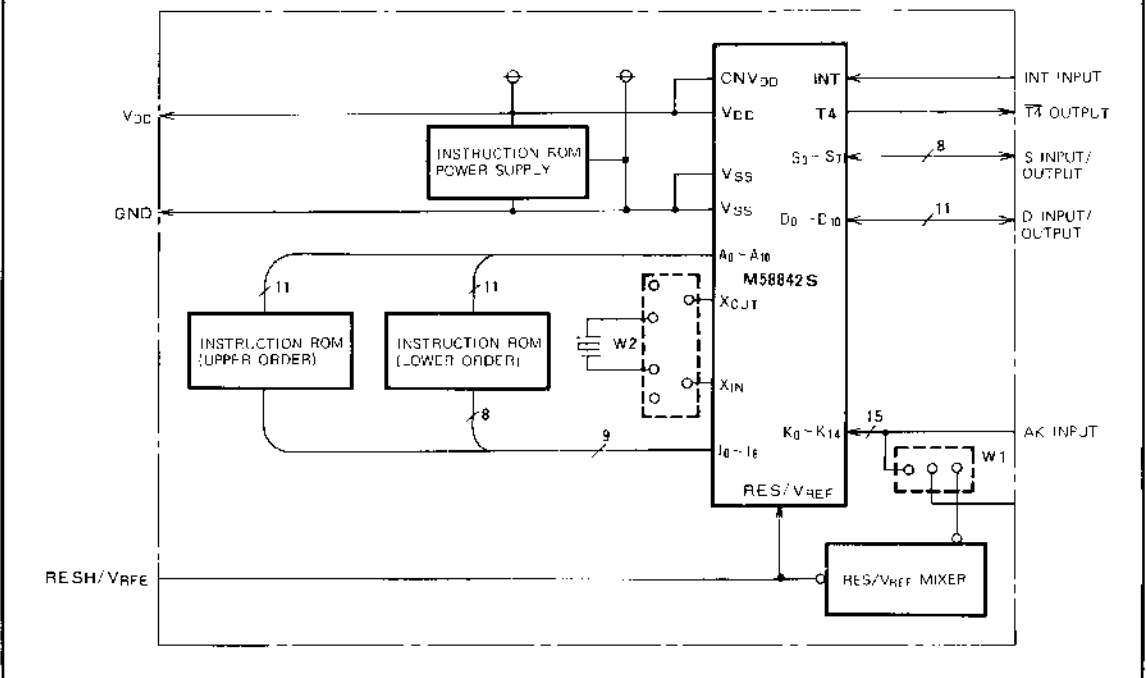

- (1) Evaluation chip and peripheral circuitry
- (2) Program EPROM socket
- (3) EPROM power supply circuit

The board and user system can be connected by means of an accessory cable.

MITSUBISHI MICROCOMPUTERS PCA4305

MELPS 4 EVALUATION BOARD

DESCRIPTION

The PCA4305 evaluation board is used as an evaluation board for MELPS 4 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58845-000SP) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58845-XXXSP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58845-XXXSP
- Simple program modification using an EPROM
- Connection to user's system by means of a cable
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 4 4-bit single-chip microcomputers.

CONFIGURATION

As can be seen in the block diagram, the PCA4305 consists of the following hardware.

- (1) Evaluation chip and peripheral circuitry
- (2) Program EPROM socket
- (3) EPROM power supply circuit

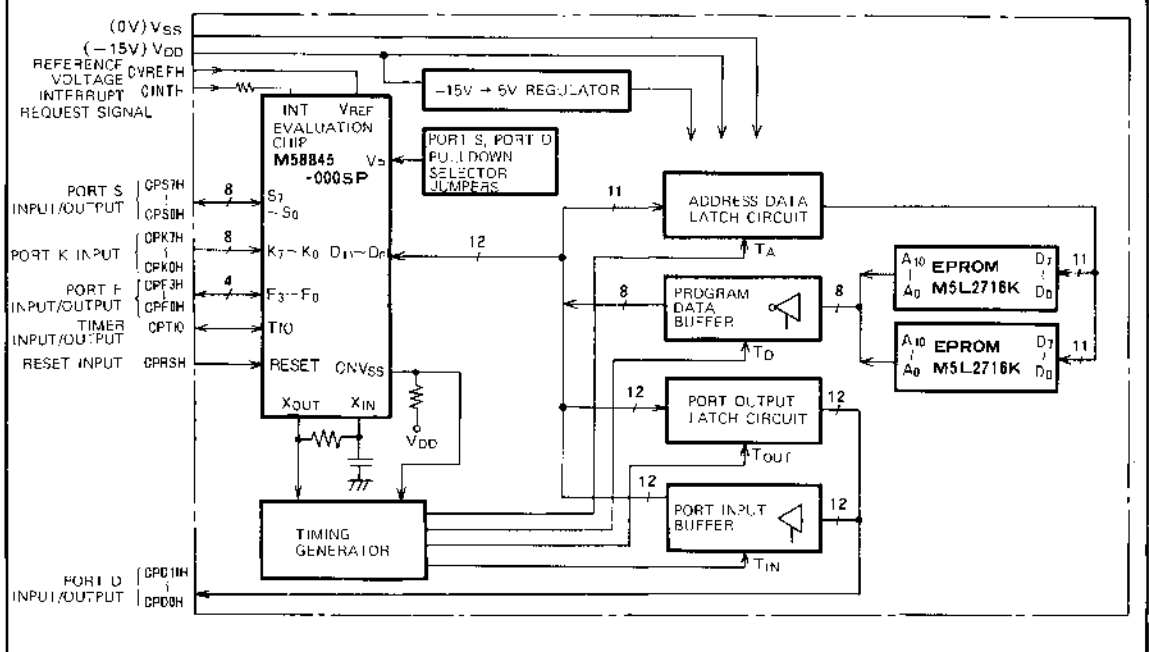

The board and user system can be connected by means of an accessory cable.

FUNCTION

The evaluation chip (M58845-000SP) outputs the value of the program counter, and reads and executes the instruction stored in the appropriate EPROM address.

It is possible to have this board emulate the operation of a single-chip microcomputer.

Clock generator		Built-in (ceramic filter or RC circuit)	
Timers		2	
Interrupts		INT pin	
Power supply		-1.5V $\pm 5\%$, 500mA (max)	
Connector used		68 conductor (34 each side) card-edge connector	
Outer dimensions		190 (L) x 180 (W) x 20 (H)mm	

DESCRIPTION

The PCA4101 evaluation board is used as an evaluation board for MELPS 41 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58494-000P) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58494-XXXP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58494-XXXX
- Simple program modification using an EPROM
- Connection to user's system by means of a cable
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 41 4-bit single-chip microcomputers.

CONFIGURATION

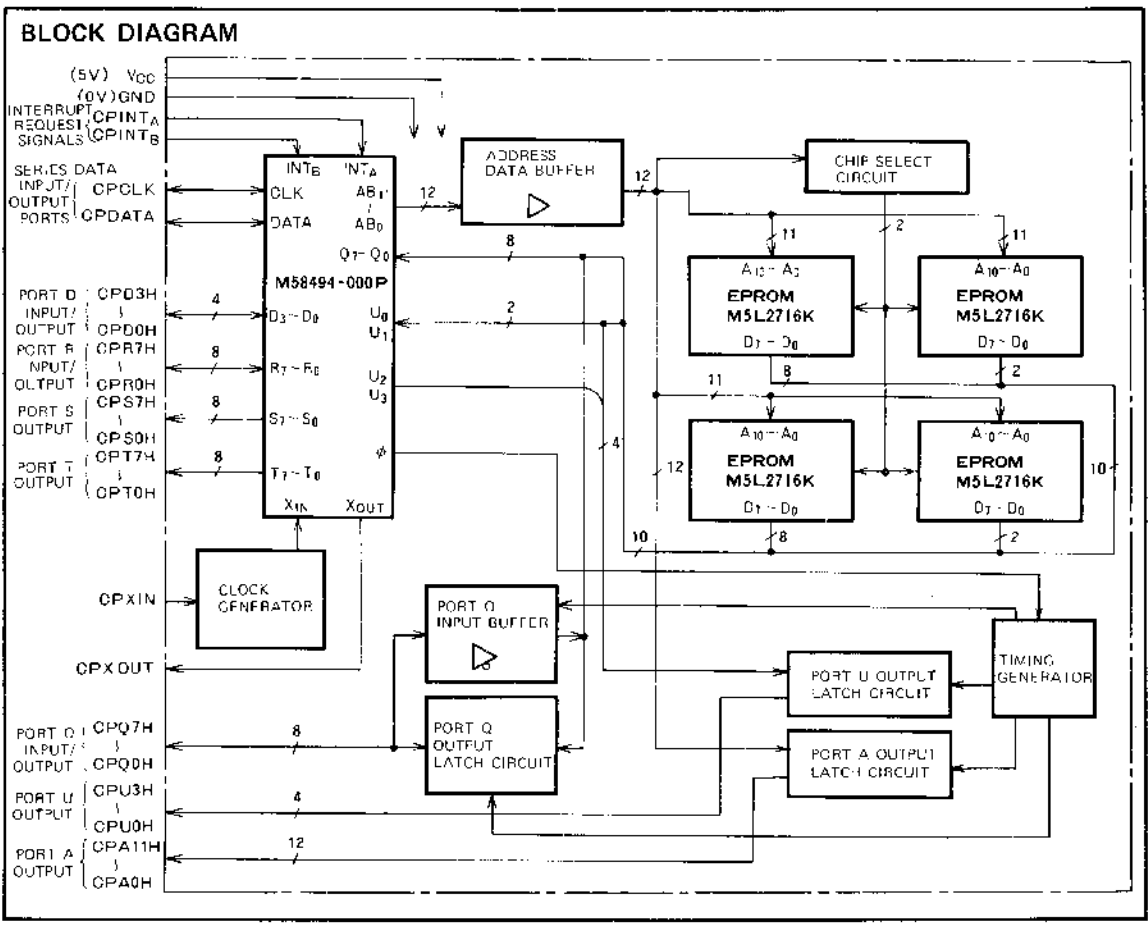

As can be seen in the block diagram, the PCA4101 consists of the following hardware.

- (1) Evaluation chip and peripheral circuitry
- (2) Address data latch circuit
- (3) Timing generator
- (4) Program EPROM socket
- (5) Port input/output latch buffers

The board and user system can be connected by means of an accessory cable.

FUNCTION

The evaluation chip (M58494-000P) performs time division of part of the port contents, outputs the value of the program counter, and reads in instructions from the EPROM and executes them. Port output buffer and latch control timing is derived from either an internal or an external clock generator. This board is usable to emulate the operation of the single-chip microcomputer.

SPECIFICATIONS

Item		Specification
Type		4-bit parallel processor
Evaluation chip		M58494-000P
Clock frequency	Internal	250kHz
	Range	100 ~ 350kHz
Memory		Program memory: 4K words x 10 bits (M5LZ718K x 4) Data memory: Internal: 32 x 4 bits External: 1024 words x 4 bits
I/O		Input/output ports: for a total of 20 lines R ₀ ~ R ₇ , Q ₀ ~ Q ₇ , D ₀ ~ D ₃ Output ports: for a total of 32 lines A ₀ ~ A ₁₁ , U ₀ ~ U ₃ , S ₀ ~ S ₇ , T ₀ ~ T ₇
Interrupts		INT _A INT _B Timer
Power supply		5 V ± 5 %
Connectors used		Two 50-pin angled headers

MITSUBISHI MICROCOMPUTERS PCA4201

MELPS 42 EVALUATION BOARD

DESCRIPTION

The PCA4201 evaluation board is used as an evaluation board for MELPS 42 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58496-000P) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58496-XXXXP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58496-XXXXP
- Simple program modification using an EPROM
- Connection to user's system by means of a cables
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 42 4-bit single-chip microcomputers.

FUNCTION

The evaluation chip (M58496-000P) performs time division of part of the port contents, outputs the value of the program counter, and reads in instructions from the EPROM and executes them. Port output buffer and latch control timing is derived from either an internal or an external clock generator. This board is usable to emulate the operation of the single-chip microcomputer.

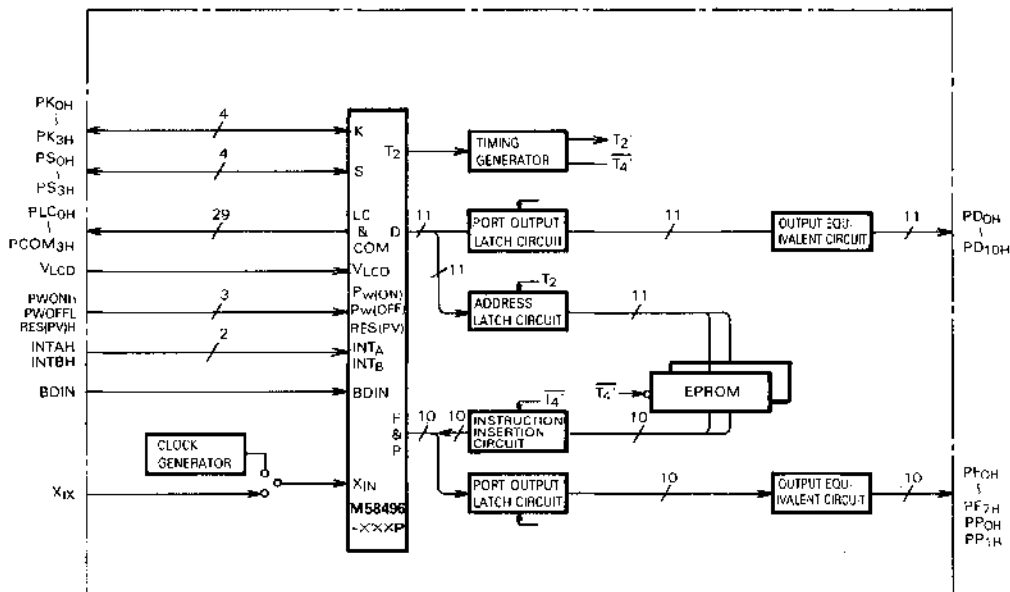

CONFIGURATION

As can be seen in the block diagram, the PCA4201 consists of the following hardware.

- (1) Evaluation chip and peripheral circuitry
- (2) Address data latch circuit
- (3) Timing generator
- (4) Program EPROM socket
- (5) Port/output latch

The board and user system can be connected by means of accessory cables.

MITSUBISHI MICROCOMPUTERS PCA4202

MELPS 42 EVALUATION BOARD

DESCRIPTION

The PCA4202 evaluation board is used as an evaluation board for MELPS 42 4-bit single-chip microcomputers.

When used in the external ROM mode, this board consists of the evaluation chip (M58497-000P) and the program EPROM (M5L2716K), possessing equivalent functions to the masked ROM M58497-XXXXP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M58497-XXXXP
- Simple program modification using an EPROM
- Connection to user's system by means of flat cables
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 42 4-bit single-chip microcomputers.

FUNCTION

The evaluation chip (M58497-000P) performs time division of part of the port contents, outputs the value of the program counter, and reads in instructions from the EPROM and executes them. Port output buffer and latch control timing is derived from either an internal or an external clock generator. This board is usable to emulate the operation of the single-chip microcomputer.

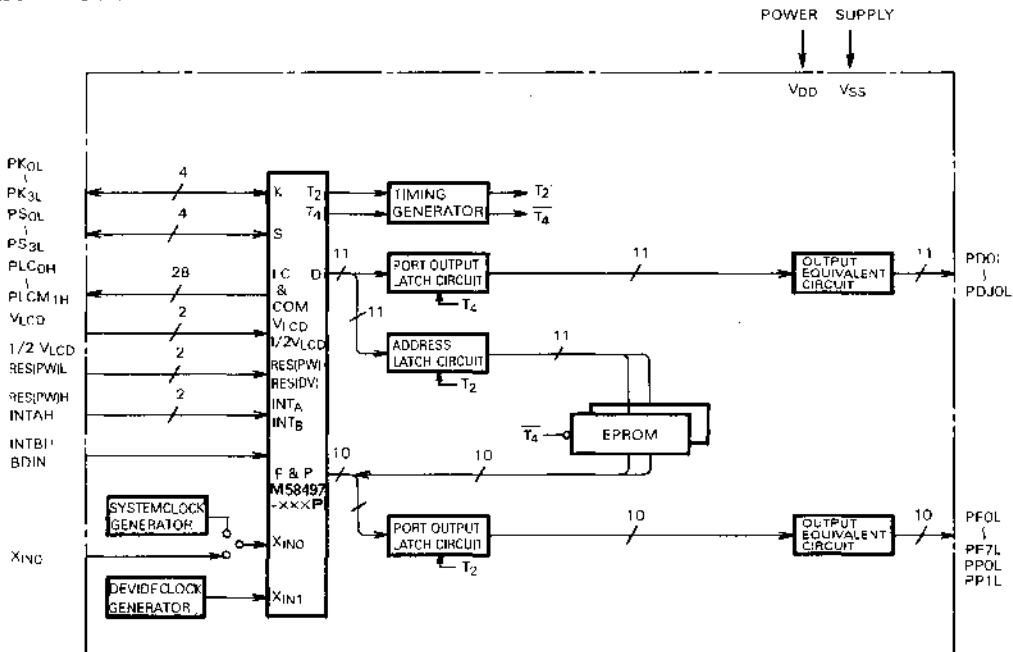

CONFIGURATION

As can be seen in the Block Diagram, the PCA4201 consist of the following hardware.

- (1) Evaluation chip and peripheral circuitry
- (2) Address data latch circuit
- (3) Timing generator
- (4) Program EPROM socket
- (5) Port input/output latch buffers

The board and user system can be connected by means of an accessory cable.

MITSUBISHI MICROCOMPUTERS PCAB402

MELPS 8-48 EVALUTION BOARD

DESCRIPTION

The PCAB402 evaluation board is used as an evaluation board for MELPS 8-48 8-bit single-chip microcomputers.

This board consists basically of the external ROM chip (M5L8039P-6) and EPROM (M5L2716K), possessing equivalent functions to the masked ROM M5L8048-XXXP and M5L8049-XXXP. When creating the mask for a developed program, this board is suitable for program verification and running tests.

FEATURES

- Board computer equivalent to the M5L8048-XXXP and M5L8049-XXXP
- Simple program modification using an EPROM
- Connection to user's system socket by means of a 40-pin DIL plug
- Built-in clock generator

APPLICATIONS

Program and applications equipment development for MELPS 8-48 8-bit single-chip microcomputers.

FUNCTION

The evaluation chip (M5L8039P-6) outputs the value of the program counter and reads in instructions from EPROM and executes them.

The board is equivalent in operation to a single-chip microcomputer.

CONFIGURATION

As can be seen in the block diagram, the PCAB402 consists of the following hardware:

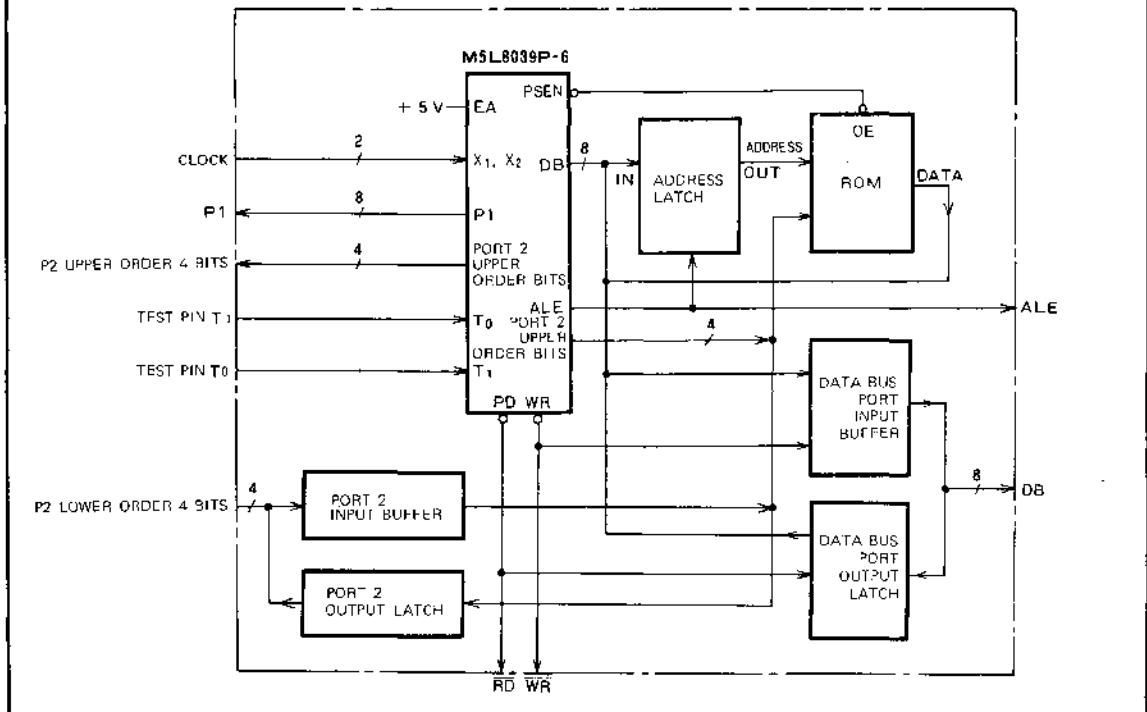

- (1) Evaluation chip and peripheral circuitry
- (2) Program EPROM socket
- (3) EPROM power supply circuit

The board and user system can be connected by means of an accessory cable.

SPECIFICATIONS

Item	Specification
Type	80bit parallel processor
CPU	M5L8039P-6 (equivalent to Intel 8039-6)
Cycle time	Clock supplied by user system (maximum 6MHz)
Memory	Program memory: 2K bytes (M5L2716K) Data memory: 128 bytes (built-in M5L8039P-6)
I/O	8-bit parallel port x3 Test pin x2
Interrupts	INT pin
Power supply	5V ±5%, 500mA (max)
Connector used	40-pin DIL IC socket
Outer dimensions	60 (L) x 65 (W) x 30 (H)mm

GENERAL DESCRIPTION

MELPS 4/41 software is the name used to designate a software series provided by Mitsubishi for development application programs for equipment in which single-chip microcomputers are used.

MELPS 4/41 software is used as a tool to develop application programs, and comprises all the programs—assembly, PROM programming and mask making—necessary to the manufacture of single-chip microcomputers.

MELPS 4/41 SOFTWARE CONFIGURATION

<p>Translates a symbolic source program written in assembly language and produces as output an object program in machine language.</p> <p>There are many kinds of control data and instruction codes and other functions can be changed easily.</p> <p>In MELPS 41, the coding format of is free and a number of input media can be used to input the source program.</p>	<p>Executes and checks a user's program on the pseudo CPU of the host computer. This allows more efficient program debugging and provides more extensive checking than can be accomplished by hardware.</p>	<p>Translates assembler binary object programs and outputs paper tape in hexadecimal form.</p> <p>Generates paper tape for PROM writers of Minaro Electronics or Takoda Rikon.</p>
	<p>Both MELPS 4 and MELPS 41 simulators feature</p> <ul style="list-style-type: none">● Many flexible control commands● Trace output, halt table and deleting● Interrupt operation capable of cyclic interruptions● Assignment of I/O ports and data <p>The MELPS 41 simulator also has:</p> <ul style="list-style-type: none">● Reverse assemble● Setting execution time count● Assignment of memory protect region	<p>M58840-XXXX and M58494-XXXX single-chip 4-bit microcomputers can be automatically programmed to customer's specifications. The plater instructions for automatic mask production and the program to test the production ROMs are automatically generated from the object program provided by the customer.</p>

MELPS 4/41 SOFTWARE

DEVELOPMENT OF APPLICATION PROGRAMS

The user can develop his application programs using MELPS 4/41 software as follows:

The cross assembler is used for object-program generation, and the simulator is used for program debugging. When the application program is finalized, the paper-tape generation program for PROM writers is used to generate a paper tape for the PROM writer.

1. EPROM: Newly developed application programs are programmed in EPROMs, using the PROM writer; then

these EPROMs are ready to be installed in sockets of an evaluation breadboard computer or other single-chip microcomputer.

2. Mask-programmable single-chip microcomputer: Mitsubishi Electric has developed a system to produce a mask-programmable single-chip microcomputer to the user's specifications. The object program can be in the PROM-writer format of either Minato Electronics or Takeda Riken.

PROGRAM DEVELOPMENT

Note 1 . With MELPS 41, paper-tape can also be used for source program input

MELPS 8/85 SOFTWARE

GENERAL DESCRIPTION

MELPS 8/85 software is the name used to designate a software series provided by Mitsubishi for developing application programs or operating systems for equipment in which MELPS 8/85 CPUs are used.

MELPS 8/85 software is divided into two parts. The first is that used as a tool to develop application programs, and

the second is that used as a part of application programs for MELPS 8/85 CPUs. MELPS 8/85 software can also be divided into two classifications: the first, host programs, which are developed to run on a host computer; and the second, target programs, which are developed to run on a MELPS 8/85 microcomputer.

SOFTWARE CONFIGURATION

<p>Compiles a source program written in PL/μ language and produces as output an object program in machine language. The complete Intel PL/M language is a subset of PL/μ. Therefore, any program written in PL/M can be compiled using a PL/μ compiler. Additional functions have been included in PL/μ that make it easy to use.</p>	<p>Executes and checks a user's program on the pseudo CPU in a host computer. This allows more efficient program debugging and provides more extensive checking than can be accomplished by hardware.</p> <p>FEATURES:</p> <ul style="list-style-type: none"> ● Provides traces and other debugging aids ● Provides simulated I/O operations ● Provides simulated interrupt operations ● Simplifies program modifications ● Provides flexibility for symbolic addresses ● Provides data for evaluation of execution time ● Batch or conversational processing can be used 	<p>Paper tapes for PROM writers can be generated by a cross compiler or a cross assembler. The tapes contain translated absolute object programs.</p> <p>Many kinds of paper tapes can be generated for the PROM writers of Takeda Riken, Minato Electronics, DATA I/O and PRO-LOG.</p>
<p>Translates a symbolic source program written in assembly language and produces as output an object program in machine language. Parts of a program can be translated and tested, after which they can be combined and linked because the individual outputs are relocatable. This makes it easy to develop modules and then combine them to form a complete program.</p>	<p>Provides data for evaluation of execution time</p> <ul style="list-style-type: none"> ● Batch or conversational processing can be used 	<p>M5873E-XXXXP 4K-byte mask-programmable ROMs can be automatically programmed to customer's specifications.</p> <p>The plotter instructions for automatic mask production and the program to test the production ROMs are automatically generated from the object program provided by the customer.</p>
<p>Translates a source program written in assembly language into an object program written in machine language for execution on the microcomputer.</p> <p>Paper-tape is used as the source-program input medium.</p> <p>The assembled object program is in MELPS 8/85 binary object format and is punched out on paper tape.</p> <p>Functions and language specifications of the assembler are included in the specifications of the cross assembler.</p>	<p>This is a basic operating monitor program to control execution of a program as well as to facilitate debugging a program. This program has a structure that makes it easy to expand or reduce the functions. DEVELOPMENT OF APPLICATION PROGRAMS

The user can develop his application programs using MELPS 8/85 software in any of three ways.

1. On a host computer: the MELPS 8/85 cross compiler or cross assembler is used for object-program generation, and the simulator is used for program debugging.
2. On a microcomputer: the MELPS 8/85 assembler is used for object-program generation, and the microcomputer is used for execution and implementation of programs.
3. On a combination of host computer and microcomputer: object programs are produced by the MELPS 8/85 cross compiler and/or the MELPS 8/85 cross assembler on a host computer. The object programs are debugged and implemented on a MELPS 8/85 microcomputer under control of the basic operating monitor.

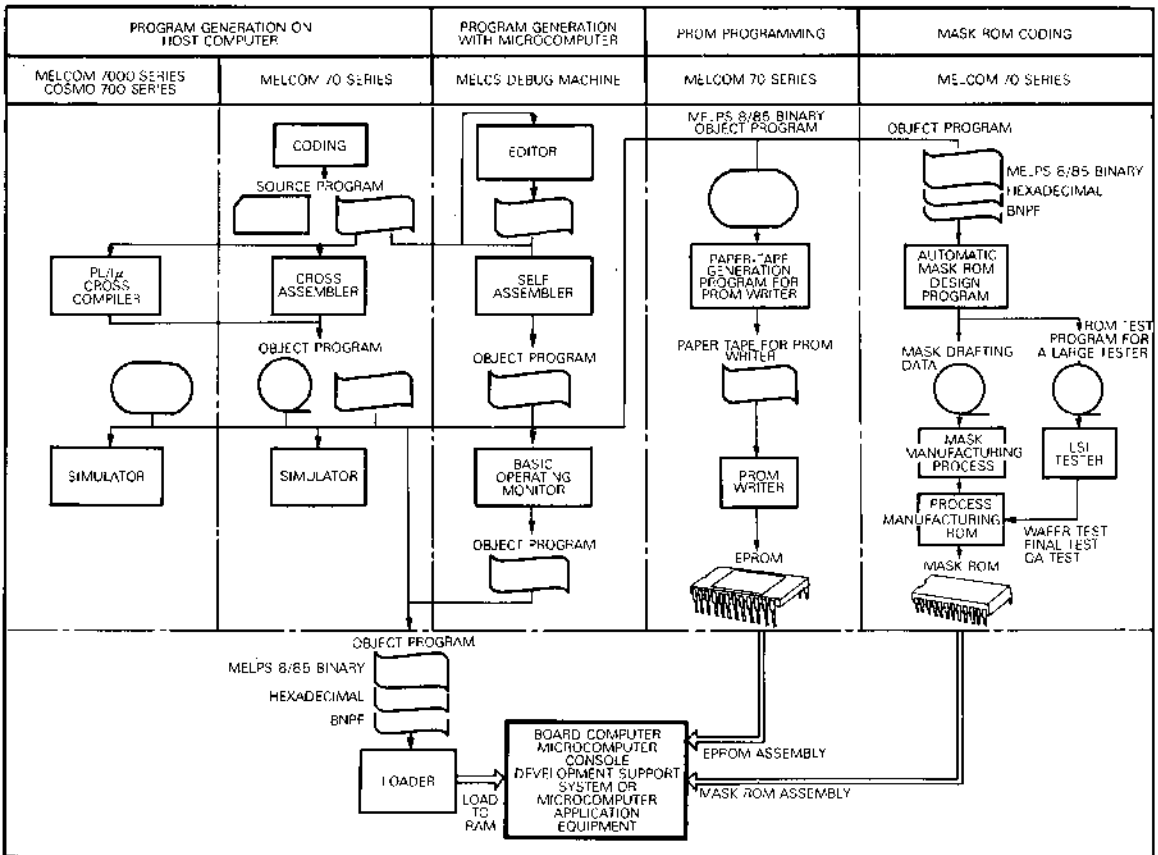

The user can develop MELPS 8/85 programs using general-purpose subroutines for functions such as arithmetic

operations, input/output control and logical operations.

Full utilization of these subroutines can facilitate program development, debugging and implementation. The final media of a developed program can be any of the following:

1. Paper tape: There are four basic forms of object programs on paper-tape: MELPS 8/85 binary, simple (IPL) binary, hexadecimal and BNPF. Object programs on paper tape are stored in RAMs and are loaded by the appropriate loader.
2. PROM: The developed program is programmed in a PROM using the PROM writer; then this PROM is installed in the appropriate PROM socket of the microcomputer.
3. Mask ROM: Mitsubishi Electric is ready to produce a mask ROM to a user's specifications. The object program can be in MELPS 8/85 binary, hexadecimal or BNPF form.

PROGRAM DEVELOPMENT

MITSUBISHI MICROCOMPUTERS MELPS 4 SOFTWARE

CROSS ASSEMBLER

DESCRIPTION

The MELPS 4 cross assembler has been prepared for the development of application programs suitable for equipment using the M58840-XXXP, M58841-XXXP, M58842S, M58843-XXXP, M58844-XXXP, M58846-XXXP and M58847-XXXP single-chip 4-bit microcomputer.

This cross assembler not only provides many pseudo instructions, control commands, and control data for improving programming efficiency, but it also provides program versatility for changing instruction codes and functions.

FEATURES OF THE CROSS ASSEMBLER

- 21 types of control data
- Instruction codes and functions easily changed
- Catalogs the control data in disk storage
- Constants can also be expressed in non-decimal notations
- Expandability using pseudo instructions
- Printouts available from the tables and cross-reference lists
- Execution computer: MELCOM 70 (memory capacity more than 24K words, monitor BDOS)
- Implementation language: FORTRAN IV (parts are written in assembly language)

FEATURES OF THE ASSEMBLY LANGUAGE

- 6 pseudo instructions
- 10 simulator control commands
- 68 machine instructions
- Decimal numbers can be used to define the constants of the machine instruction operand field.

INPUT/OUTPUT MEDIA

- Source input : Punched cards and magnetic disk
- Control data input : Punched cards and magnetic disk
- Control data command : Punched cards
- Execution command : System typewriter keyboard
- Object output : Magnetic disk
- Output lists : Line printer

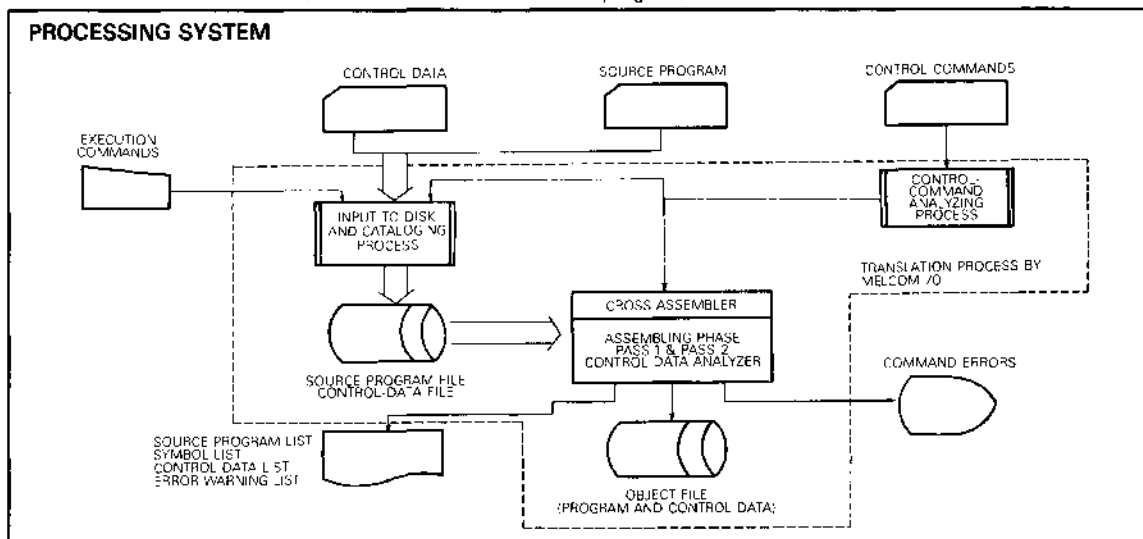

FUNCTION

This cross assembler converts source programs written in the MELPS 4 assembly language to machine instruction codes that are filed in disk storage in the form of binary absolute object codes.

The MELPS 4 cross assembler is a 2-pass translator that provides data and control command analysis along with cataloging functions.

Modifying the number of bits in an instruction code and setting mnemonic tables and numeric tables to constants can easily be accomplished by means of the control data. In this way, programming versatility is provided for changing functions, allowing the user free selection in defining the mnemonics of the machine instructions, etc.

The standard version of the MELPS 4 assembly language has 7 assembler control commands (see Table 1). In addition 6 pseudo instructions and 10 system simulator control commands (Table 2) can all be used in the source language program.

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included

		GBM-SR10-01A<93A0>

CROSS ASSEMBLER

CROSS ASSEMBLER

This cross assembler facilitates assembly by the use of the control commands shown in Table 1. Basically, it only requires the source program and control commands input by punched cards with control data being utilized only when necessary. All input is stored and filed in disk storage. The control data is processed by the control command analyzing processor, and the symbol table is created in pass 1. This is followed by pass 2, where each instruction is converted to machine language, while control data, labels and the assembly list are printed out as specified by the control commands. On the assembly list, the control commands, sequence numbers, location numbers and addresses are printed out, along with error and warning messages, followed by the ROM page list and the cross-reference list.

OBJECT LANGUAGE

The object file is composed of a name section and a text section.

The name section is filed on sector 0 of the object file and stores overall information such as the total number of instructions in the text section, control data, file name, source program file name, size of a single page and the module name.

The text section contains the data that controlled the conversion of the source program to instruction codes and other related data necessary for execution by the simulator.

ASSEMBLY LANGUAGE

The assembly language that the MELPS 4 cross assembler accepts consists of machine instructions and pseudo instructions.

1. Machine Instructions

There are 68 basic machine instructions. These are converted to their corresponding machine codes and then assembled into an object program. For the mnemonics, instruction codes and their functional descriptions, please refer to the data sheet provided for the M58840-XXXP single-chip 4-bit microcomputer.

2. Pseudo Instructions

Although the pseudo instructions are written in the source program together with machine instructions, they are not converted to instruction codes but are used to control the assembler and the simulator. The instruction codes will be written in the ROM.

The system simulation control instructions are among the pseudo instructions along with assembler-control instructions, numeric symbols defining instructions and list-control instructions. The pseudo instructions are shown in Table 2.

Table 1 Assembler control commands

Command	Format	Function	
Execution start	/// RUN	Starts execution of the cross assembler	
Execution end	/// END	Term inates execution of the cross assembler	
Input/output function assignment	/// ASMB4, x, y, z	Assignment of assembly executor and control data and assembly listings $x = \begin{pmatrix} A \\ P \end{pmatrix}$ x : Assembly control A : Assembly needed $y = \begin{pmatrix} L \\ N \end{pmatrix}$ y : Designation of data logging function y : Assembly listing $z = \begin{pmatrix} L \\ N \end{pmatrix}$ z : Control data listing L : Listing needed N : No listing needed	
File assignment control	Control data	/// CDISK, XXXXX	Assignment of the control file name (max. 6 characters)
	Source program	/// SDISK, XXXXX	Assignment of the source program file name (max. 6 characters)
	Object	/// BDISK, XXXXX	Assignment of the object file name (max. 6 characters)
Input/output device assignment	/// INPUT, x, y	Assignment of input device for the control data and source program $x = \begin{pmatrix} C \\ D \end{pmatrix}$ x : Control data input y : Source program input $y = \begin{pmatrix} C \\ D \end{pmatrix}$ C : Punched card input D : Disk input	

Table 2 Pseudo instructions

Classifier	Mnemonic	Instruction	Function
Assembler control instructions	TTL	Program title declaration	Declares the program title
	PAGE	Program counter paging	Sets the counter to the top address of the next page
	ORG	Program counter setting	Sets the counter to the top address of the program
	END	End declaration	Declares the end of the program
Symbol value equi- valence instruction	EQU	Symbol value setting	Sets a numerical value to the specific numerical symbol
List control instruction	EJE	Page eject declaration	Advances the printout form to the next page during output
	SIN	Data input	Reads the input data
	RIN	Mode cancellation	Cancels * * * mode input
System simulator control instructions	SDIS	Display content printout	Prints out the contents of the display
	RDIS	SDIS presetting	Enables execution of the SDIS instruction
	SSC	Step counter selection	Selects the step counters
	RSC	SSC presetting	Enables execution of the SSC instruction
	WSC	Step counter content printout	Prints out the contents of the step counters
	RWSC	WSC presetting	Enables execution of the WSC instruction
	SINT	Terminal input	Starts input from the terminal assigned
	RINT	SINT presetting	Validates execution of the SINT instruction

Note 1. Validation refers to the execution of one command before another to enable its function. For example, to execute the SSC instruction the RSC instruction must be executed first.

3. Language Format

The following format should be used in coding programs in this cross assembler.

The single-line statement is composed of the label, instruction, operand, comment, and identification fields. The format of the source statement is fixed as indicated in Fig. 1. Although the constant is usually a decimal number, it may be expressed by hexadecimal notation and other notation when defined by pseudo instructions and control data.

An asterisk (*) in the first column of a line indicates that the entire statement is used as a comment field.

The following are valid characters for use in statements:

- Alphabets: A~Z
- Numerics: 0~9
- Special characters: ; , * \$ + - * / ! & () . # % < > ? (space)

Fig. 1 Source statement format

(1) Label field

The value of the program counter at that time is set to the label. The number of characters used for a label is limited to a maximum of 6, and any of the alphanumeric and special characters specified above can be used. However, an asterisk (*) cannot be used in the first column of the label field.

(2) Instruction field

Mnemonic codes are written in this field, left-justified. For pseudo instructions, any of the mnemonics among the assembler-control instructions, numeric symbol definition instructions, list-control instructions, and system simulator control instructions may be used.

(3) Operand field

Parameters of the instruction are specified in this field. This field contains the label, defined symbol, or numerical value. The operand is stated from the 14th column, left-justified.

(4) Comment field

Whenever the operand is followed by more than one space to the end of the statement, the successive columns may be used for comments.

(5) Identification field

The use of this field is optional. Many find it convenient to use this field for a sequential identification card number.

ASSEMBLY LIST FORMAT

A source program prepared and assembled in the format indicated in the preceding paragraph may produce source, symbol table, cross reference, and ROM page list printouts. The format of an assembly list produced as an example is shown in Fig. 2. Please note that pages, locations, and object codes are indicated in hexadecimal notation.

MESSAGE FORMAT

Error and warning messages are printed out on the assembly list. In the case of errors, the message is printed out under the respective statement in the following format:

\$\$\$\$\$ERROR xxx\$

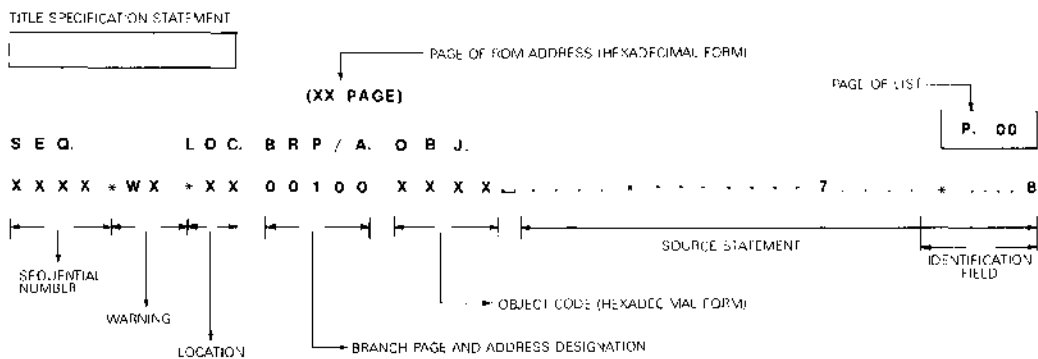

where "xxx" indicates the type of error by a numerical code.

In the case of warnings, the following message is printed between SEQ (sequential number) and LOC (location number):

* Wx * (where "x" indicates the degree of warning)

In addition the total numbers of errors and warnings are printed on the last line of the assembly list. The cross-reference list, however, will not be produced when any errors are indicated.

Fig. 2 Assembly list format

Example of an assembly list

An actual example of an assembly list, for an assembly made with the MELPS 4 cross assembler, is shown in Fig. 3.

Fig. 3 Example of an assembly list

34				END	EXA0110

- ① The program name is declared as "EXAMPLE PROGRAM".
- ② It shows that the start of the program was set to page 0 address 0 by means of the program counter setting instruction.
- ③ An asterisk (*) in the first column indicates that the entire statement is a comment.
- ④ Numeric value 13 (decimal number) is assigned to the symbol DIGMAX by means of the symbol value equivalence instruction.
- ⑤ The label XCG02 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 14 address 00.
- ⑥ The label XCG13 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 12 address 01.
- ⑦ The label XCG25 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 14 address 07.
- ⑧ This whole statement line is used as a comment * end.
- ⑨ The numerical value 0 is loaded in register X of the data pointer and 13 (decimal number) in register Y by means of the LXY instruction. As written, the results of this LXY instruction are nullified by the results of the following LXY instruction.
- ⑩ The numerical value 1 is loaded in register X of the data pointer and 13 (decimal number) in register Y by means of the LXY instruction.
- ⑪ The BM instruction in this case assigns the branch address of the label LBL4 to address 02 of page 14.

MITSUBISHI MICROCOMPUTERS MELPS 4 SOFTWARE

SIMULATOR

DESCRIPTION

The MELPS 4 simulator software has been prepared for facilitating program debugging for application programs suitable to equipment using single-chip 4-bit microcomputers. It also allows a significant saving of program-development time.

With this simulator, each instruction of the microcomputer is executed on a host computer just as though the program were being executed on an actual microcomputer system. This allows confirmation that the operations and sequences of a program are correct before the microcomputer system is built. Various control commands such as traces and halt tables are available for use during program development. The program, which was assembled and stored in disk storage by the MELPS 4 cross assembler, can then use this simulator to simulate its execution. The results of the simulation are printed out along with other helpful information for verification and debugging of a program under development.

FEATURES

- Trace and halt tables
- 20 control commands
- 10 control instructions that can be used along with pseudo instructions during source-program preparation
- Selective printout of input data for verification
- Selection of display digits (1~12 digits)
- Indication of each register, I/O port and memory file, etc

INPUT/OUTPUT MEDIA

- Object input: Cartridge disk storage
- Control commands: Punched card/keyboard and input data
- Execution commands: Keyboard input
- Trace dump: Input/output of the table by paper tape
- Simulation: Output of the result through the line printer or the system typewriter
- Messages: System typewriter

APPLICATIONS

- In conjunction with the MELPS 4 cross assembler as a tool for developing application programs for 4-bit microcomputers
- Especially useful for debugging programs prepared for the M58840-XXXX

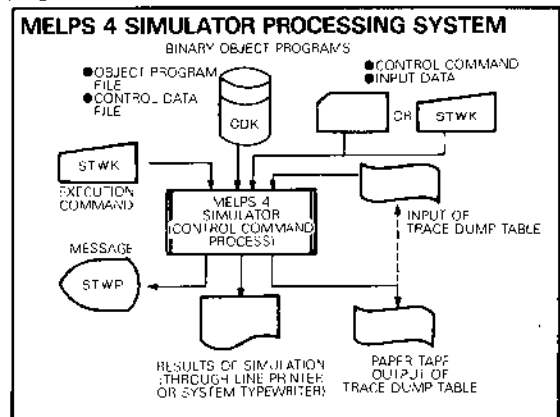

FUNCTIONS

Various control commands are provided by the MELPS 4 simulator to help determine if the program is operating properly according to original specifications. These control commands can set operating conditions and halt program

process, while indicating the system status, CPU state, and memory contents.

This simulator has 20 control commands, including trace dump, trace and halt tables, clear, printout of tables, set registers or stack pointers and carry flags, selective printout of input data, input/output of paper tape, etc. that may be used to facilitate debugging.

It also has 10 simulator-control pseudo instructions that may be assigned during the preparation of the source program.

Simulator

Binary object codes stored in the disk file (BDISK), generated by the MELPS 4 cross assembler, are processed in this program according to the conditions given by the control commands, and the result can be selectively printed out on the line printer or the system typewriter. Input and control data can be input through the card reader or the keyboard depending on the mode selected.

Input data format

Input data format of the simulator is shown below:

XXYY \cup n₁n₁n₁n₁ \cup n₂n₂n₂n₂

where, "XX" (or *, \$) indicates the input symbol, and "YY" (or -, ** - ON, OFF) the input mode symbol.

"n₁n₁n₁n₁" the analog value (digital) under on-state.

"n₂n₂n₂n₂" the analog value (digital) under off-state.

Control command input format

Normally, the control commands are expressed in the following format, but its relation with control commands is described in Table 1.

///XX \cup (parameter)

where, "XX" indicates the mnemonic of the control command.

There are two input modes: type-in mode or batch mode. But the simulator start ST command should be entered from the keyboard.

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Software manuals included
MELPS 4 simulator	GB1SM 0001	MELPS 4 Simulator Manual MELPS 4 Simulator Operating Manual GBM-S10-01A<93A0>

Table 1 Simulator control commands

Functional classification	Item	Control commands		Functions
		Action	Mnemonic	
Simulator control commands	Start condition setup	Starts simulation	ST	Designates the control command input device and the simulation result output device and assigns control data output
	Load program	Loads the object program	LO	Loads the absolute object program
	Command input reassignment	Reassigns the control command input	CM	Changes the command input device to another device
	Finishes simulation	Stops simulation	FN	Terminates the program execution, and control is returned to the monitor
Execution control commands	Trace	Trace region assignment started	TS	Assigns trace regions where the contents of the program counter, registers, and memory file will be printed out while being executed
		Trace region assignment discontinued	TD	Discontinues trace region assignment
		Printout of the trace table	PT	Prints out the trace table
	Halt	Halt-point assignment started	HS	Assigns halt points by page number, address and times of execution
		Halt-point assignment discontinued	HD	Discontinues halt-point assignment
		Printout of the halt-point table	PH	Prints out the halt-point table
	Data setup	Initialization of the program counter, registers, memory file, etc	MM	Sets the initial data to the program counter, registers, I/O ports, memory file, etc
		Resets of the program counter, registers, memory file, etc	CL	Resets the program counter, registers, I/O ports, memory file, etc
	Data printout	Printout of the data in the program counter, register, memory file, etc	DM	Dumps the contents of the program counter, registers, I/O ports, memory file, etc
		Dumps the trace and halt-point tables	DT	Outputs the contents of the trace and halt-point tables on paper tape
	Dump table	Reads the trace and halt-point tables	RT	Inputs the data of the trace and halt-point tables from paper tape
		Printout of the input data	PK	Prints out the contents of the periodical input data while the program is in execution
	Data input	Release of input data printout	NK	Releases printout of the contents of the periodical input data while the program is in execution
		Device assignment for data input	DV	Assigns the input device for the input data
	Program start	Continuance of program execution	RN	Starts to execute the program without changing the contents of the program counter, registers, I/O ports, memory file, etc
		Program execution	RS	Starts to execute the program after initializing the contents of the program counter, registers, I/O ports, memory file, etc

APPLICATION EXAMPLE

Once the command ST and its parameter are typed in through the system typewriter keyboard, successive commands may be entered through punched cards or the system typewriter keyboard. The command input device may be changed at any time by using the CM command.

Simulation is started on the object file in the disk storage that was stored there, after assembling, by the MELPS 4 cross assembler. When the MELCOM 70 is used, the simulator program should be called by the command EXEC SIML4 to start simulating operation.

The following commands must be assigned when tracing and executing the simulated program. Assignment of the input and printer devices, along with selection of the desired list printout, is entered by the ST command in the format ST, X, Y, Z. Here X represents the input device (S for the system typewriter and C for the card reader), Y represents the output device on which the simulation result is printed out (L for the line printer device and S for the system typewriter and W for both), Z represents the

need for the control data list output (L to output the control data list and N for omitting output).

The stored object program (BDISK file) is loaded by the simulator with the LO command in the format: LO file name.

The CL and MM commands should be used when initialization is required. When the program counter, registers, I/O ports, and memory file are to be cancelled, the command CL may be used. The format of the MM command is:

MM XXXX = nnnn

It is used in setting initial values. XXXX represents the symbol or numerical figure by which the program counter, registers, I/O ports or memory files are designated. And nnnn represents a parameter to be given.

Entry of the HS command:

HS pp: aa, nnnn

will make the machine halt at address aa of page pp after that instruction has been executed nnnn times.

Entry of the TS command:

TS p₁p₁: a₁a₁, p₂p₂: a₂a₂ [,R] [,M]

sets flags to make a trace effective from address a₁a₁ of page p₁p₁ to address a₂a₂ of page p₂p₂. R designates the output of the contents of the registers and M the memory file.

When the DM command is executed, the contents of each register and memory file at the time are printed out.

Program execution is commenced with the RS or RN command and continues until a location is reached that has been designated by the parameter of an HS command to print out its result. The RS command designates a start after cancelling the contents of the program counter, registers, I/O ports and memory file.

The assignment of the trace region is discontinued with the TD command, and the halt-point assignment with the HD command. The trace table is printed out with the PT

command, and halt-point table with the command PH, whenever required. Paper-tape dump and input of the trace and halt-point table is assigned with the DT and RT commands. To set up for input data, there are the PK command, which prints out the contents during the execution of selected data input, and the NK command, which discontinues printing. For the assignment of the input device, the DV command is provided.

Besides the above commands, 10 simulator-control pseudo instructions are used during source-program preparation and during simulation.

A typical example of the use of the MELPS 4 simulator control commands is shown in Table 2, and the results of a simulation example of the assembled program of Fig. 1, is shown in Fig. 2.

Table 2 Example of the use of simulator control commands

Command	Parameters	Function of the control command and its parameter(s)
ST	S, I, N	To start simulation, the I/O are assigned and control data is omitted or output. In this example, command input is assigned to the system typewriter, printout is assigned to the line printer and the list of the control data is omitted.
LO	BFILE	The file stored in the disk (BDISK) whose file name is BFILE is loaded.
CL		The program counter, registers, I/O ports and file memory are cleared and set to initial values.
HG	0: 5, 2	This assigns a halt-point. In this example, it will halt after the second execution of the instruction n address 5 of page 0.
TS	0: 1, E: F, R.	This command designates a trace from address 1 of page 0 to address F of page E, and orders display of the contents of the program counter, registers, and I/O ports after completing tracing.
PT		This command prints out the trace-table table. Assignments made by TS commands can be verified by this command.
PH		This command prints out the halt-point table. Assignments made by HS commands can be verified by this command.
MM	0, 1-2	The contents of column 1 of the memory file F _n are set to 2.
DM		The contents of the program counter, registers, I/O ports and memory file at the time this command is executed are printed out.
RN		Program is started without changing the contents of the program counter, registers, I/O ports and memory file.

** END SIMULATOR OF MELPS 4 **

```

- ① The file stored in the BDISK whose file name is 0H ILE is loaded
- ② The program title that was declared at the time of source program preparation is printed out
- ③ The contents of the program counter, stack pointer, registers, I/O ports and memory file are cancelled and set to initial conditions
- ④ The contents of address 0 of page 0 of the object program is printed out on the system typewriter by means of the data setup command in order to allow a location in the program code and to identify correct loading of the program.
- ⑤ Tracing is directed from address 0 of page 0 to address 4 of page 0 and the contents of the registers are displayed
- ⑥ This assigns a halt after once executing the program in address 4 of page 0.
- ⑦ Tracing designation in step ⑤ is discontinued by releasing the trace-region assignment
- ⑧ A new trace region is assigned. In this example, tracing is directed from address 0 of page 0 to address 5 of page 0, and the contents of the registers and memory file are to be printed out
- ⑨ The trace table is printed out in order to confirm that the trace has been registered correctly
- ⑩ This prints out the contents, in their initial states, of the program counter, registers, stack pointer, I/O ports and memory file.
- ⑪ The contents of the program counter, stack pointer etc. are printed out.
- ⑫ The contents of CPS, (either one of a pair of the data pointers or the carry is selected), ACC (accumulator), CY1 and CY2 (carry), DP1 and DP2 (data pointer), Z (file assignment) and Y (digit designation in the file) are printed out.
- ⑬ This indicates each bit in the contents of the ports D and S and the registers J and E
- ⑭ This indicates the contents of the interrupt request INT, interrupt acknowledge flag INTLF and the condition given for the INTHL
- ⑮ This indicates the contents of the registers, B, H, L and C respectively
- ⑯ The contents of the memory file before the execution of the program are printed
- ⑰ The program execution is started, and trace is carried out in accordance with the assignment given at step ⑧ and continues to indicate the contents of registers and memory file and then to halt at the halt point designated in step ⑥
- ⑱ The DM command is entered to print the contents of registers, etc. at the time the execution is terminated
- ⑲ This shows that each file in F₀ and F₂ is exchanged with F₁ and F₃ after executing the program shown in Fig 1
- ⑳ The simulation is now terminated, and control has returned to the monitor

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

DESCRIPTION

MELPS 4 PROM writer paper tape generation programs are used to convert the absolute binary object program generated by the MELPS 4 cross assembler into another format that can be used in a PROM writer. The program is output on paper tape in the new format.

With this program, a binary object program can easily be converted to hexadecimal object format that can be programmed directly into a PROM. It can produce paper tapes that meet the requirements for various types of PROMs and PROM writers because of its functional versatility.

FEATURES

- Outputs the binary object program in the disk storage to paper tape in hexadecimal format
- Paper tape output can be partitioned with a simple control command
- May be used in conjunction with the MELPS 4 cross assembler
- Execution computer: MELCOM 70 Minicomputer (memory capacity more than 16K words, monitor BDOS)
- Programming language: FORTRAN IV (parts are written in assembly language)

INPUT/OUTPUT MEDIA

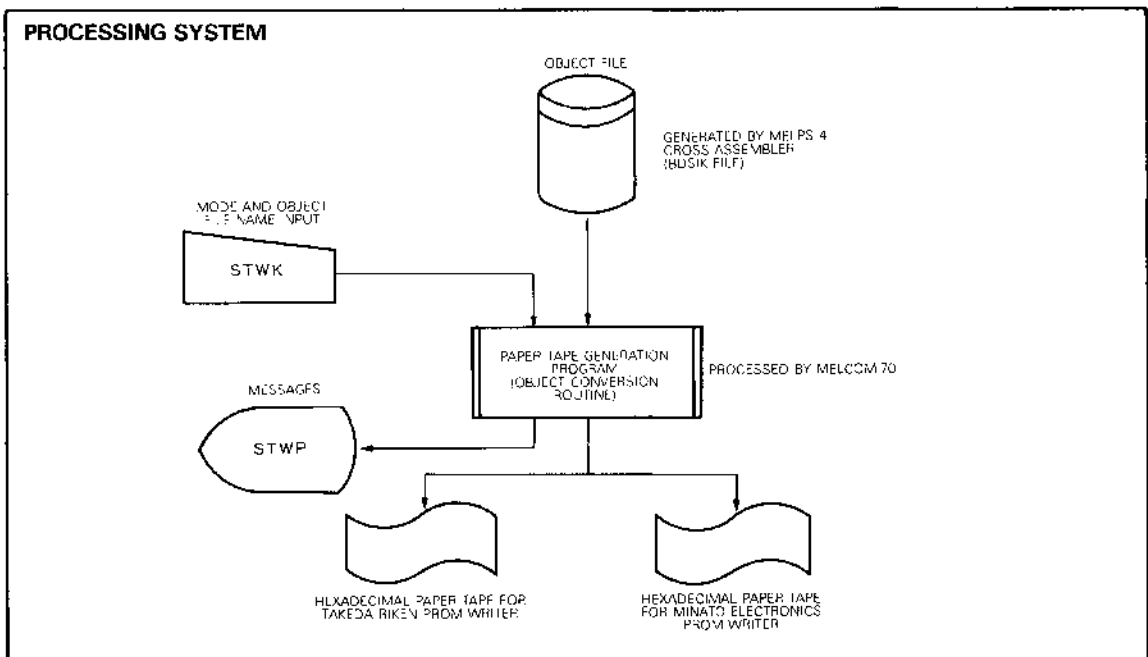

- Input: Cartridge disk storage
- Output: Paper tape (ASCII code, even parity)
- Control command input: Through the keyboard of the system typewriter
- Messages: System typewriter printout

APPLICATIONS

- For preparing programs for 1K words X 8-bit EPROMs (M5L2708S), etc., which are to be programmed by PROM writers supplied by Takeda Riken or Minato Electronics.

FUNCTION

This program is used for converting the absolute binary object format programs generated by the MELPS 4 cross assembler to hexadecimal object format compatible with the PROM writers manufactured by Takeda Riken (T310) and Minato Electronics (model 1830 and 1802). The paper-tape output is partitioned in accordance with PROM capacity (number of bytes).

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included
MELPS 4 paper tape generation program for PROM writer	GBISP0001	MELPS 4 paper tape generation program for PROM writer manual MELPS 4 paper tape generation program for operating manual GBM-SR10-01A<93A0>

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

PROGRAM PROCESSING

The program has conversion routines for Takeda Riken's and Minato Electronics' PROM writer. Select T₁ mode (for Takeda Riken's PROM writer) or M₁ mode (for Minato Electronics' PROM writer) through the system typewriter keyboard. Then the object program is converted to paper tape compatible with the selected PROM writer. When a (BDISK file) file name is called, a paper tape is output for the PROM writer. When a number of programs are to be converted from the same file, successive calls can be made until all the programs are converted. Termination of the job is directed with the E command, and control is then returned to the monitor.

The object file consists of name and text segments. The data to be converted is contained in the text segment. Instruction codes stored after sector 1 of the disk that correspond to machine instructions are converted to hexadecimal codes and output to paper tape.

Example of Hexadecimal Paper Tape Format

This program can generate paper tapes for Takeda Riken's PROM writer and Minato Electronics' PROM writer. Examples of both formats are shown in Figs. 1 and 2.

Example of Object Conversion

The program at present can output 1K-word units of paper tape up to a total of 4K words. An example is shown in Fig. 3.

Error Processing

When an error is encountered during object conversion, a message will be printed out in the following format:

\$\$\$\$\$\$ XXX\$

where, XXX indicates the error code.

Fig. 3 Example of object conversion

Fig. 1 Example of hexadecimal paper tape format of Takeda Riken

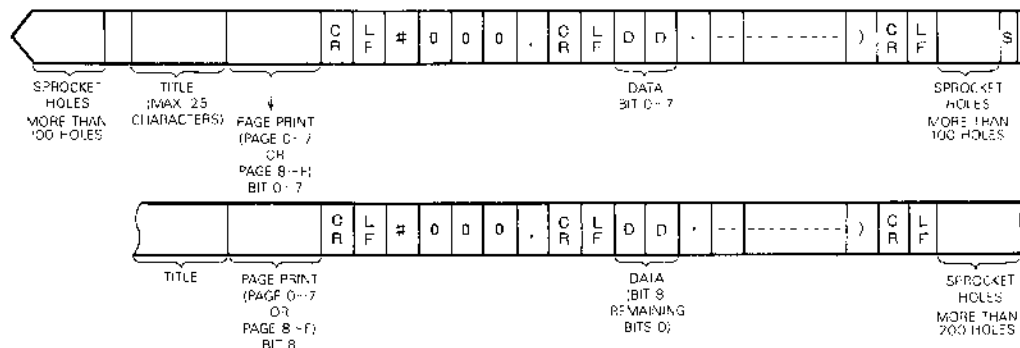

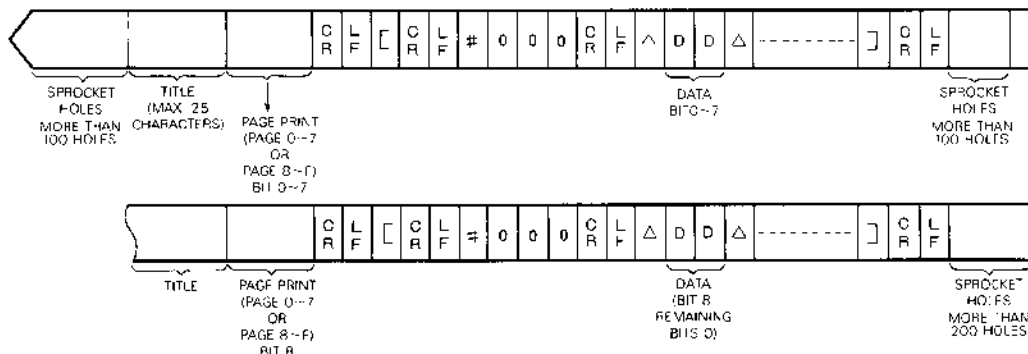

Fig. 2 Example of hexadecimal paper tape format of Minato Electronics

CROSS ASSEMBLER

DESCRIPTION

The MELPS 41 cross assembler has been prepared for the development of application programs suitable to equipment using the M58494-XXXP single-chip 4-bit CMOS micro-computer.

This cross assembler allows coding in free formats for improved programming efficiency and permits the use of various input media. It also provides program versatility for changing instruction codes and functions thanks to the control commands and control data employed.

FEATURES

Of the Cross Assembler

- Free-format coding.
- Various source-input media available
- Instruction codes and functions easily changed
- Catalogues the control data in disk storage
- Constants can also be expressed in non-decimal formats
- Numerical formula in the operand field can be processed
- Printouts available from the tables and cross-reference lists
- Execution computer: MELCOM 70 (memory capacity more than 24K-words, monitor BDOS)
- Implementation language: FORTRAN IV (parts are written in assembler language)

Of the Assembly Language

- 9 pseudo instructions
- 1 macro instruction
- 93 machine instructions
- The constants of the machine-instruction operand field can be defined using decimal numbers.

INPUT/OUTPUT MEDIA

- Source input: Punched cards, punched tapes, magnetic disk, and magnetic tape
- Control-data input: Punched cards, punched tapes and magnetic disk
- Control-data command: Punched cards and system-typewriter keyboard
- Object output: Magnetic disk and punched tapes
- Output lists: Line printer and system typewriter

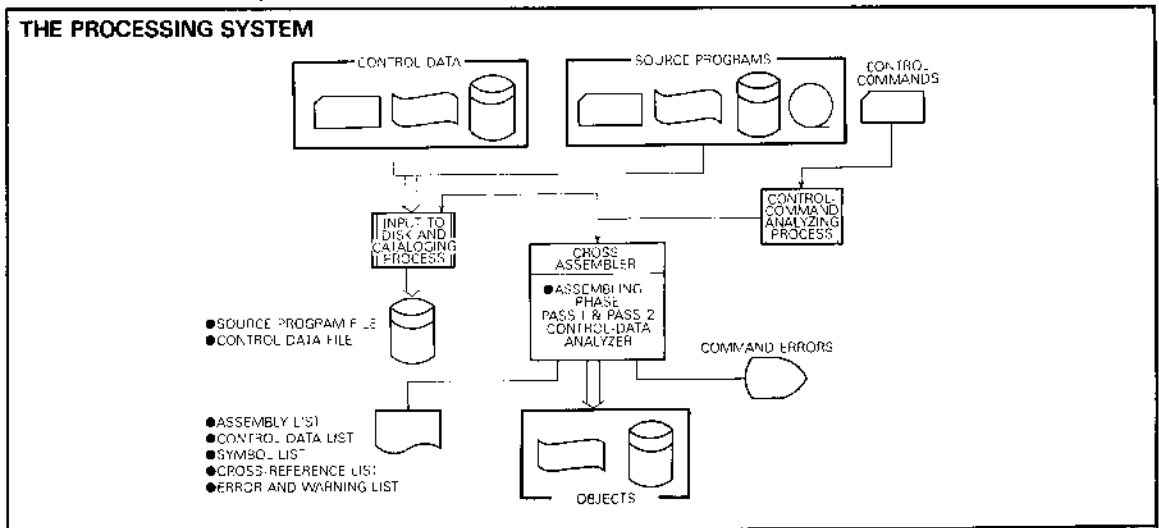

FUNCTION

This cross assembler converts source programs written in the MELPS 41 assembly language to machine instruction codes, which are filed in disk storage in the form of binary absolute object codes.

The MELPS 41 cross assembler is a 2-pass translator that provides data and control command analysis along with cataloging functions.

Modifying the number of bits in an instruction code and setting mnemonic tables and numeric tables to constants can easily be accomplished by means of the control data. In this way, programming versatility is provided for changing functions, allowing the user free selection in defining the mnemonics of the machine instructions, etc. Codes corresponding to the MELPS 41 mnemonics are displayed in a 10-bit form.

The MELPS 41 assembler language has 9 assembler

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included
MELPS 41 cross assembler	GB1AS0003	MELPS 41 Assembler Language Manual MELPS 41 Cross Assembler Manual MELPS 41 Cross Assembler Operating Manual

CROSS ASSEMBLER

control commands listed in Table 1 and 9 pseudo instructions (see Table 2).

CROSS ASSEMBLER

This cross assembler facilitates assembly by using the commands listed in Table 1. The source program and control data can be input by punched cards, punched tapes, magnetic tapes and magnetic disks. The control data can also be input by using these types of media. It is very convenient to prepare standard control data and store it in the magnetic disk if it rarely needs changes. The control data is processed by the control-command analyzing processor, and the symbol table is created in pass 1. This is followed by pass 2, where each instruction is converted to machine language, while control data, labels and assembly lists are printed out as specified by the control commands. In this case, the object codes in the assembly list are displayed in hexadecimal form. The control commands, sequence numbers, location numbers for all pages, locations of the pages to be jumped to, and source statements are printed out. In addition, error and warning messages are displayed, followed by the output of ROM-page and cross-reference lists.

OBJECT LANGUAGE

The disk object file is composed of a name section and a text section. In the case of punched tapes, the file consists of a name section, text section and an end-of-tape section.

The name section of a disk object file is filed on sector 0, and stores information such as the total number of instructions in the text section and control data.

Table 1 Assembler control commands

Command		Format	Function
Input/output function assignment		///ASM41, X, Y, U, Z	Assignment of assembly execution, object output, and control-data and assembly listings $X = \begin{pmatrix} A \\ P \end{pmatrix}$ X: Designation of assembly execution $U = \begin{pmatrix} O \\ D \end{pmatrix}$ U: Designation of object output A: assembly needed P: Cataloging function (N) O: Object output needed $Y = \begin{pmatrix} N \\ L \end{pmatrix}$ Y: Designation of assembly listing $Z = \begin{pmatrix} L \\ N \end{pmatrix}$ Z: Designation of control-data listing L: Listing needed N: No listing needed
Input-device assignment control		///INPUT, X, Y, Z	Assignment of input devices for the control data and source program and of magnetic-tape codes $X = \begin{pmatrix} O \\ D \\ P \\ N \end{pmatrix}$ X: Designation of control data input O: Card reader D: Disk $Y = \begin{pmatrix} O \\ D \\ P \\ M \end{pmatrix}$ Y: Designation of source-program input P: Punched-tape reader M: Magnetic tape N: No input $Z = \begin{pmatrix} A \\ E \end{pmatrix}$ Z: Code assignment E: EBCDIC code A: ASCII code
Output-device assignment control		///OUTPUT, X, Y	Assignment of object-output device and character selection for the single output-list line $X = \begin{pmatrix} D \\ P \end{pmatrix}$ X: Designation of object-output device $Y = \begin{pmatrix} C \\ B \\ O \end{pmatrix}$ Y: Designation of the no. of characters in a line D: Disk P: Punched tape C: Blank B: 80 characters O: 80 characters Blank 120 characters
File assignment control	Control date	///CDISK, XXXXXX	Assignment of the control-data file name (max. 6 characters)
	Program	///SDISK, XXXXXX	Assignment of the source-program file name (max. 6 characters)
	Object	///BDISK, XXXXXX	Assignment of the object file name (max. 6 characters)
Date assignment control		///CDATE, YY, MM, DD	Assignment of the year, month and day YY: Year (2 digit) MM: Month (2 digit) DD: Day (2 digit)
Execution-start control		///RUN	Starts execution of the cross assembler.
Execution-end control		///END	Terminates execution of the cross assembler.

The text section is filed from sector 1, and contains the data that controlled the conversion of the source program into instruction codes and other related data necessary for execution by the simulator.

ASSEMBLY LANGUAGE

The assembly language that the MELPS 41 cross assembler accepts consists of machine instructions, pseudo instructions, and macro instructions.

1. Machine Instructions

There are 93 basic machine instructions. These are converted to their corresponding machine codes and then assembled into an object program. For the mnemonics, instruction codes and their functional descriptions, please refer to the machine-instruction list of the M58494-XXXP.

2. Pseudo Instructions

Although the pseudo instructions are written in the source program together with machine instructions, they are not converted to instruction codes but are used to control the assembler. The instruction codes will be written in the ROM.

The pseudo instructions include assembler-control numeric-symbol defining, list-control, and memory-address setting instructions.

3. Macro Instructions

These instructions give one-word expressions for combined used of several machine instructions. When internal or external memory-address setting is to be carried out by using 'LXx,' 'LYy,' and 'LZz' RAM address instructions, for instance, the macro instruction (LZXY symbol) can be used instead.

Table 2 Pseudo instructions

Classification	Mnemonic	Instruction	Function
Assembler-control instructions	TTL	Program title declaration	Declares the program title
	ORG	Program counter setting	Sets the counter to the top address of the following program
	PAGE	Program counter paging	Sets the counter to the top address of the next page
	PAUSE	Assembly pausing	Stops the assembly for a short time (effective only for bus transfer delay)
	END	End declaration	Declares the end of the program
Symbol, label, operand, comment, and control data	EQU	Symbol definition setting	Sets a predetermined value to a specific numerical symbol
	EJE	Page eject declaration	Advances the printout form to the next page during output
Memory address setting	INTM	Internal memory address setting	Sets the internal memory address to the specified value
	EXTM	External memory address setting	Sets the external memory address to the specified value

Table 3 Macro instructions

Instruction	Function
LZX* $\#n$ ¹⁾	1) When the $\#$ is set by the INTM instruction, expansion is made into LXx and LYy instructions. 2) When the $\#$ is set by the EXTM instruction, expansion is made into LZz, LXx and LYy instructions.

Note 1 $\#$ is specified by the INTM or EXTM instruction; symbol n is hexadecimal and $0 \leq n \leq 4095$

4. Language Format

The following format should be used in coding programs in this cross assembler.

The single-line statement of the source program is composed of the label, instruction, operand, comment, and identification fields. Format of the source statement is free, as indicated in Fig. 1. Although the constant is usually a decimal number, it may be expressed by hexadecimal notation when defined by pseudo instructions and control data.

The following are valid characters for use in statements.

- Alphabetics: A~Z
- Numerics: 0~9
- Special characters: ; = , ▼ @ \$ + - * / ! & () , # % < > ? (blank)

(1) Label field

The value of the program counter at that time is set to the label. Any of the alphanumerics and special characters specified above can be used. The character : (colon) is placed at the rear end of the label field.

However, an asterisk (*) cannot be used in the first column of the label field.

(2) Instruction field

Mnemonic codes are written in this field. In addition to the machine instructions, use can be made of pseudo instructions such as the assembler-control, numeric-symbol definition, list-control, and memory-address setting instructions.

(3) Operand field

Parameters of the instruction are specified in this field. The field contains the label, defined symbol, or numerical value. It is usually necessary to leave a blank of one character or more behind the instruction.

(4) Comment field

This field is used for writing notes for the statement and is not converted to an object in the process of changing the source statement into its corresponding object.

Writing an asterisk(*) in the first column of the source statement enables the whole statement to be used as a comment.

Whenever the instruction or operand field is followed by more than one space, the successive characters may be regarded as comments.

(5) Identification field

The use of this field is optional. Many operators find it convenient to use it for the sequential identification card number.

Fig. 1 Source statement format

Note 2 A colon (:) is placed behind the label.

ASSEMBLY LIST FORMAT

A source program coded and assembled in the format indicated in the preceding paragraph may produce assembly-list, symbol-table-list, cross-reference-list, and ROM-page-list printouts. The format of an assembly list produced as an example is shown in Fig. 2. Please note that pages, addresses, locations, and object codes are indicated in hexadecimal notation.

MESSAGE FORMAT

Error and warning messages are printed out on the assembly list. In the case of errors, the message is printed out under the respective statement in the following format:

\$\$\$\$\$ERROR0xxx0\$ (Error message)

where 'xxx' indicates the type of error by a numerical code. The total number of errors is printed on the last line of the assembly list. The cross-reference list, however, will not be produced when any error is indicated.

Fig. 2 Example of an assembly list

- ① The program name is declared as "MELPS 41 EXAMPLE PROGRAM"
- ② An asterisk (*) in the first column indicates that the entire statement is a comment.
- ③ Numerical value 10 (decimal number) is assigned to the symbol 'A' by means of the symbol-value equivalence instruction
- ④ The value Z, X, Y = 2, 0, 0 is assigned to the symbol REG1 by means of the external-memory address-setting instruction
- ⑤ The value X, Y, 1, 0 is assigned to the symbol REG2 by means of the internal-memory address-setting instruction.
- ⑥ The following program is assigned to address 10 (hexadecimal number) of page 0 by means of the program-counter setting instruction
- ⑦ The numerical value 10 (decimal number) assigned to the symbol A is loaded in register A
- ⑧ The numerical value 1 is loaded in the page register
- ⑨ The value assigned to symbol REG1 is expanded in LZ, LX and LY instructions
- ⑩ The label INTEX is assigned by means of the BM instruction during assembly process and calls the subroutine starting at page 1 address 3
- ⑪ The value assigned to symbol REG2 is expanded in LX and LY instructions
- ⑫ The label EXTIN is assigned by means of the BM instruction during assembly process and calls the subroutine starting at page 1 address 0
- ⑬ The program-counter page number is advanced to that of the next page

MITSUBISHI MICROCOMPUTERS MELPS 41 SOFTWARE

SIMULATOR

DESCRIPTION

The MELPS 41 simulator software has been prepared for facilitating program debugging of application programs suitable to equipment using the M58494-XXXP CMOS single-chip 4-bit microcomputer or microprocessors. It also allows a significant saving of program-development time.

With this simulator, each instruction of the microcomputer is executed just as though the program were being executed on an actual microcomputer system. This allows confirmation that the operations and sequences of a program are correct from a software point of view before the microcomputer system is built. Simulations using various simulator control commands are possible, and the results of the simulations are printed out along with other helpful information for verification and debugging of the program under development.

FEATURES

- An ample 26 control commands
- Production and deletion of trace and halt tables are possible
- Interruption-generation setting and periodical interruption are possible
- I/O port -setting function
- Data-setting function
- Execution-time counting function
- Reverse assembly is possible
- Memory-protection area-setting function
- Execution computer: MELCOM 70 (memory: 24K-words or larger)
- Implementation language: FORTRAN IV (parts are written in assembler language)

INPUT/OUTPUT MEDIA

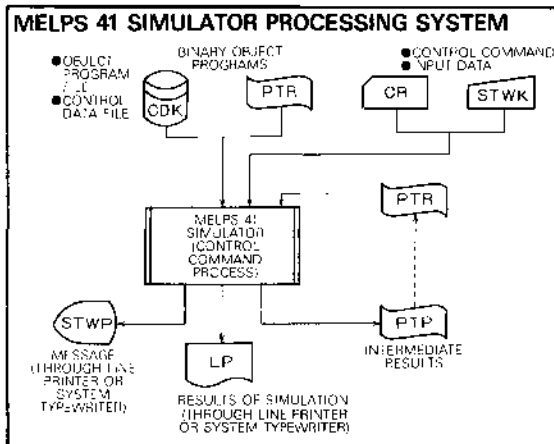

- Object input: Cartridge-disk storages, punched tapes
- Control commands: Punched cards and system-type-writer keyboard
- Intermediate results: Punched tapes
- Simulation results: Line printers and system typewriters
- Messages: Line printers and system typewriters

APPLICATIONS

In conjunction with the MELPS 41 cross assembler as a series of tools for developing application programs for single-chip 4-bit microcomputers. Especially useful for debugging programs prepared for the M58494-XXXP CMOS microcomputer.

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Software manuals included
MELPS 41 simulator	GB1SM0002	MELPS 41 Simulator Manual MELPS 41 Simulator Operating Manual

FUNCTION

Various simulator control commands are provided by the MELPS 41 simulator to help determine if the program is operating properly according to original specifications. These control commands can set operating conditions and halt program processes, while indicating the system status, CPU state and memory contents in a trace mode. Interruption-generation setting is also possible.

This simulator allows the production and deletion of trace and halt tables, table printouts, and the setting and printed indication of registers, stack pointers, carry flags, memories, and I/O ports. The 26 control commands can also be used for interruption generation, timer setting and reverse assembly.

SIMULATOR

Binary object codes stored in the disk file (BDISK), generated by the MELPS 41 cross assembler, are processed in this program, and a simulation is carried out according to the conditions given by the simulator control commands. The results of the simulation can be selectively displayed on a line printer or system typewriter. It is also possible to output or input intermediate results by means of punched tapes.

The simulator control commands are classified into (1) simulator control instructions for starting and ending simulations, loading and saving programs, and changing I/O devices, and (2) execution-control instructions for controlling simulation-execution status.

Control-Command Input Format

///XX□ (parameter)

XX: Specified by a 2-character symbol (26 kinds).

Parameter: A required parameter can be selected from those which have been defined in the control

Table 1 Simulator control commands

Function classification	Item	Control commands		Functions
		Action	Mnemonic	
Simulator control commands	Simulator start-up	Specification of simulation-start conditions	ST	Designates the control-command input device and the simulation-result output device, and sets them to start status.
	Execution-program setting	Execution-program loading	LO	Loads the absolute object program (designates input device file name).
	Program saving	Execution-program saving	SV	Outputs intermediate results of the program content, register, port, F/F, timer, and memory in punched tape.
	Designation of simulation output device	Selection of command-input and simulation-result output devices	DV	Designates the command-input device and simulation-result output device by using the device symbol.
	Simulator termination	Simulation-termination designation	FN	Terminates the program execution, and control is returned to the monitor.
Execution control commands	Trace	Trace-region assignment started	HS	Sets starting and termination addresses to the trace region, traces, and executes while printing out the contents of the registers, ports, timer, and memory as specified.
		Trace-region assignment discontinued	TD	Discontinues trace-region assignment by table-number designation.
		Printout of the trace table	PT	Prints out the trace table.
	Halt	Halt-point assignment started	HS	Assigns halt points by page number, address and times of execution.
		Halt-point assignment discontinued	HD	Discontinues halt-point assignment.
		Printout of the halt-point table	PH	Prints out the halt-point table.
	Data setting	Initialization of the program counter, registers, memory file, etc.	MM	Sets the initial data to the program counter, registers, I/O ports, memory file, etc.
		Reset of the program counter, registers, memory file, etc.	CL	Resets the program counter, registers, I/O ports, memory file, etc.
	Data printout	Printout of the data in the program counter, registers, ports, flip-flop devices, memory, timer, etc.	DM	Dumps the contents of the program counter, registers, I/O ports, memory, flip-flop device, timer, etc.
	Port control	Input-port control	IN	Controls the input-port data read-in device and the input port by print-mode designation.
		Export-port control	OT	Designates an output device for the data obtained from the output port.
	Interruption	Interruption-generation assignment started	IT	Sets interruption conditions such as interrupt on type, interruption-generation, head address, and generation cycle number.
		Interruption-generation assignment discontinued	ID	Deletes the interruption-generation table.
		Printout of the interruption-generation table	PI	Prints out the interruption-generation table.
	Execution step time	Execution-time setting and printout	TI	Sets the execution timer and prints out the number of execution steps.
	Memory protection	Memory-protection-region assignment started	PS	Designates the kind of memory, starting and termination addresses of the protected region, and inhibits write-in steps.
		Memory-protection-region assignment discontinued	PD	Discontinues the memory-protection assignment by the memory-protection table number.
Printout of the memory-protection region		PP	Dumps the contents of the memory-protection table.	
Execution start	Program execution on start-up	RN	Starts simulation execution. Termination by executing the halt point and the execution-limit stop number.	
	Program execution	GO	Starts simulation execution. Termination by halt-point execution. Trace-region assignment is invalid here.	
Reverse assembly	Reverse assembly control	PA	Reverse-assembles the specified region and prints out the source list.	

command. A comma (,) is used to divide one parameter from another.

The following are parameter-configuration examples: reserved word, address indication, numerical-value setting, numerical-value indication, and time setting.

1. Reserved word

This symbol is classified according to its function in the simulator, and specifies a predetermined character symbol, program counter (PC), memory, register, and port.

///MM REGS A = 9

2. Address indication

Address indications for the internal memory, external memory and ROM are possible.

///DM EXT M, 0:1:E, 0:A:5 External memory address indication

///DM INT M, 0:0, 1:0

Internal memory address indication

///MM PROG, OF:23

ROM address indication

3. Numerical value setting

A numerical value is set for each function parameter.

///MM FFLG, CY = 1

4. Numerical value indication

Decimal or hexadecimal notation is used.

///MM TIME, T1 = E

5. Time setting

The specified time is set.

///TI SET, 8:15:3

(Note : This parameter means 8ms, 15, 3μ sec.)

APPLICATION EXAMPLES

Once the command ST (this is used for specifying simulation-start conditions) and its parameter are typed in through the system-typewriter keyboard, successive commands may enter through punched cards or the system-typewriter keyboard. It is also possible to designate command-input and result-printer devices by setting the DV-command parameter.

Simulation is started on the object file in the disk storage that was stored there, after assembling, by the MELPS 41 cross assembler. When the MELCOM 70 is used, the simulator program should be called by the command //EXEC SIM41 to start simulating operation. The following are examples of command assignment in the case of tracing and execution during system-application program simulation.

Assignment of the input and printer devices is entered by the ST command in the format ST₁X, Y, where X represents the input device (S for the system typewriter, and C for the card reader; no designation equals the S designation in effect), and Y represents the output device on which the simulation result is printed out (L for the line printer and S for the system typewriter; no designation equals the L designation in effect).

The stored object program (BDISK file) is loaded by the simulator with the LO command in the format LO₁ file name. The CL command should be used for clearing the initial values and the MM command for setting initial values.

When the program counter, registers, I/O ports and memory file are to be cancelled, the command CL may be used. The MM command in the format of MM₁XXXX₁nnn

can be used for setting their values. Here XXXX represents the symbol or numerical figure by which the program counter, registers, I/O ports or memory files are designated, while nnn represents a parameter to be assigned.

Designating the halt command HS PP: aa nnnn will make the machine halt at address aa of page PP after that instruction has been executed nnnn times.

Entry of the TS command

TS₁P₁:a₁a₁, p₂p₂:a₂a₂, R, P, I, X₁:Y₁, X₂:Y₂(, E, Z₁:X₁:Y₁, Z₂:X₂:Y₂)

makes possible the assignment that a trace is to be carried out from address a₁a₁ of page p₁p₁ to address a₂a₂ of page p₂p₂. Here R designates the output of the contents of the registers and F/F print; P designates the ports and timer print; and I and E respectively designate print modes for the internal and external memories.

When the DM command is executed, the contents of each register, port, flip-flop device, memory, timer, and program counter are printed out.

Interruption can be carried out by the IT, ID and PI commands. The IT command designates the kind of interruption, the head address of interruption generation, and the number of generation cycles. ID discontinues the interruption-generation assignment, and PI effects interruption-generation table printouts.

The TI command can be used for execution timer setting and printouts. The PS, PD and PP commands are provided for memory protection. PS designates the memory-protection-region assignment, PD discontinues the memory-protection-region assignment in accordance with the memory-protection table number, and PP prints out the contents of the memory-protection-region.

Table 2 Examples of the use of simulator control commands

Application examples of control command	Function of the control command and its parameters
///ST ₁ S, L	To start simulation, the command input and simulation result printout devices are assigned. In this example, command input S is assigned to the system typewriter, and printout L to the line printer.
///LO ₁ D, BFILE	The file stored in the disk (BDISK) whose file name is BFILE is loaded.
///CL ₁ INTM, 0:0, 0:F	The designated internal memory is cleared from digit 0 to digit F of the 0 file.
///HS ₁ 5:F, 2	This assigns a halt point; in this example it will halt after the second execution of the instruction in address F of page 5.
///TS ₁ 0:5, E:F, R, P	This command designates a trace from address 5 of page 0 to address F of page E, and orders display of the contents of each register, flip-flop device, port and timer after completing tracing.
///IT ₁ INTA, 0:F, 5	This effects the generation of interruption A starting at address F of page 0 and after every 5 steps after that.
///PT ₁ INTA, 0:F, 5	This command prints out the trace table. Assignments made by TS commands can be verified by this command.
///PH	This command prints out the halt-point table. Assignments made by HS commands can be verified by this command.
///MM ₁ PORT, Q=A5	This sets A5 to port Q.
///MM ₁ INTM, 0:0 0:0 0=1 0:1 0=.	This command changes the value 0 in digit 0 of file 0 to 1.
///DM	The contents of the program counter, registers, I/O ports, flip-flop devices, memory, and timer at the time this command is executed are printed out.
///RN 50	This starts the execution of simulation, which is stopped when the halt point address is reached or when the number of execution steps reaches 50.

Execution is started by the RN and GO commands, and it is continued to the point specified by the HS parameter. In the case of RN the machine is stopped by executing the limit-step number and the IDLE instruction. In the case of GO, termination is effected after the execution of the IDLE instruction, and the trace-region assignment becomes invalid.

The assignment of the trace region is discontinued with the TD command, and the halt-point assignment with the HD command. The trace table is printed out with the PT command, and halt-point table with the command PH, whenever required.

The IN and OT commands can be used for I/O-port control. The DV command is provided for designating devices for command input and simulation-result printout.

Application examples of the use of the MELPS41 simulator control commands are listed in Table 2, and the results of a simulation example are shown in Fig. 1.

- ① The operation start-up of the MELPS 41 simulator is designated. At this time, it is specified that the control command is to be input through the system typewriter and the results of simulation output on the line printer.
- ② The program is loaded from the file BFILE of the disk.
- ③ Data is set from the 0:0 of the internal memory. The value 0 of the memory 0:0 is set to 1. The value 0 of the memory 0:1 is set to 2. The assignment is ended without changing the value 0 of memory 0:2.
- ④ Data is set from 2:1:0 of the external memory. The value 0 of the memory 2:1:0 is set to A (hexadecimal number). The assignment is ended without changing the value 0 of memory 2:1:1.
- ⑤ The address inside the program-counter page is set to 10 (decimal number).
- ⑥ Tracing of the region from address 16 of page 0 to address 17 of page 0 is designated, and the contents of the region from 2:0:0 to 2:1:F of the external memory are printed out.
- ⑦ When address 16 of page 0 is executed, the contents of the flip-flop device and register are printed out.
- ⑧ With the halt point set to address 1A of page 0, termination after a single execution is specified.
- ⑨ The contents of the registers and flip-flop device are printed, out.
- ⑩ The trace-region table is printed out.
- ⑪ The halt-point table is printed out.
- ⑫ The execution counter is initialized.
- ⑬ The program execution is started. Trace is carried out in accordance with the assignment given by steps ⑤ and ⑦ and is terminated at the halt point designated by step ⑧. Otherwise, termination is entered when 100 steps are executed.
- ⑭ The contents of the external memory before transferring the contents of the internal memory to it are printed.
- ⑮ This shows that the 16-digit data from 0:0 to 0:F in the internal memory have been transferred to the region 2:0:0-2:0:F of the external memory.
- ⑯ The contents of the internal memory before transferring the contents of the external memory to it are printed.
- ⑰ This shows that 16 digit data from 2:1:0 to 2:1:F in the external memory have been transferred to the region 1:0-1:F.
- ⑱ The number of steps executed and the execution time are printed.

MITSUBISHI MICROCOMPUTERS MELPS 41 SOFTWARE

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

DESCRIPTION

The MELPS 41 PROM writer paper-tape generation program is used to convert the absolute binary object programs generated by the MELPS 41 cross assembler into another format that can be used in a PROM writer. The program is output on paper tape in the new format. This program also allows converting paper tapes in hexadecimal form into binary objects.

With the MELPS 41 program, a binary object program can easily be converted to hexadecimal object format that can be programmed directly into an EPROM. It can produce paper tapes that meet the requirements for various types of EPROMs and PROM writers because of its functional versatility.

FEATURES

- Outputs the binary object program in the disk storage to paper tapes in hexadecimal format
- Converts hexadecimal-form paper tapes into binary objects
- Comparison function
- Outputs PROM-writer format selectively
- Paper-tape output can be partitioned with a simple control command
- May be used in conjunction with the MELPS 41 cross assembler
- Execution computer: MELCOM 70 minicomputer (memory capacity, more than 16K-words; monitor, BDOS)
- Programming language: FORTRAN IV (parts are written in assembly language)

INPUT/OUTPUT MEDIA

- Input: Cartridge-disk units, paper tapes (ASCII code, even parity)
- Output: Paper tapes (ASCII code, even parity), cartridge-disk units
- Control-command outputs: Through system-typewriter keyboard
- Message: System-typewriter printout

APPLICATIONS

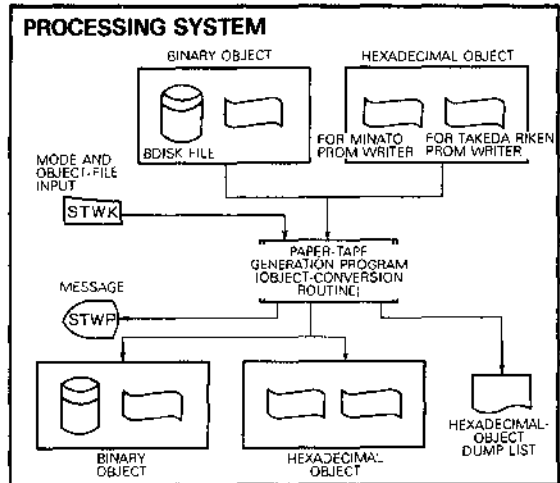

For preparing programs for EPROMs (M5L2708K, S M5L2716K, etc.) that are to be programmed by PROM writers supplied by Takeda Riken (T310) or Minato Electronics (Models 1830 and 1802).

FUNCTION

This program is used for converting the absolute binary object programs that were generated by the MELPS 41 cross assembler in the disk area to a hexadecimal object format compatible with Minato Electronics Models 1830

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included
MELPS 41 Paper-tape generation program for PROM writers	GB1SP0003	MELPS 41 paper-tape generation program for PROM writer manual MELPS 41 paper-tape generation program for PROM writer operating manual

and 1802 and Takeda Riken (T310). The paper-tape output is partitioned in accordance with EPROM capacity (number of bytes). The program also permits the processing of hexadecimal-format object paper tapes for input conversion and storage in the disk in a binary object format. Outputs on paper tapes are also available.

PROGRAM PROCESSING

The program has routines for selectively converting binary objects processed with the MELPS 41 cross assembler into paper tapes for Takeda Riken's and Minato Electronics' PROM writers.

Object conversion can be carried out by designating the input and output modes. For example, select BD mode for input and T1 mode for output (for Takeda Riken's PROM writer) or BD mode for input and M1 mode for output (for Minato Electronics' PROM writer) through the system-typewriter keyboard. Then the object program is converted to paper tapes compatible with the selected PROM writer only by calling the object file (BDISK file) into which it is to be converted and then putting in the number of paper-tape outputs. By putting the paper tapes after conversion into the disk of file 1 when the original data are in file 2, their contents can be compared with each other. The file-comparison function allows easy checking of the validity of the converted paper tapes.

It is also possible to input hexadecimal-format paper tapes, to store them in the disk as a binary-object file, and to output them on paper tapes. In this case, the binary-object paper tapes are composed of name, text and end segments. After completion of the conversion, control can be returned to the monitor by the EN command.

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

The object disk file consists of name and text segments. The data to be converted is contained in the text segment. Instruction codes stored after section 1 of the disk that correspond to the machine instructions are converted into hexadecimal codes and output to paper tapes.

Example of Hexadecimal Tape Output

This program can generate paper tapes for Minato Electronics' and Takeda Riken's PROM writers. It can output 8 paper tapes in 1K-byte units at maximum. Examples are shown in Figs. 1-3.

Example of Object Conversion

This program can output 1K-word units of paper tape up to a total of 8K-words. Fig. 4 shows an example in which conversion is made from an absolute binary object (disk) to paper tape.

Fig. 4 Example of object conversion

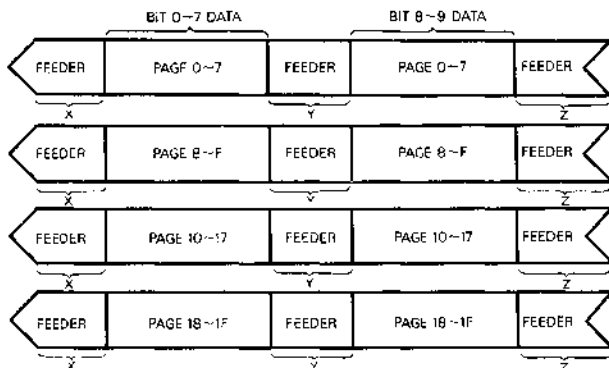

Error Processing

When an error is encountered during object conversion, an error message will be printed out in the following format:

\$\$\$\$\$ ERROR XXX

where XXX indicates the error code.

Fig. 1 Example of hexadecimal paper-tape output

Note: X, Y and Z denote the numbers of the sprocket holes: X: 100 or more, Y: 200 or more, Z: 200 or more.

MITSUBISHI MICROCOMPUTERS MELPS 42 SOFTWARE

CROSS ASSEMBLER

DESCRIPTION

The MELPS 42 cross assembler has been prepared for the development of application programs suitable for equipment using the M58496-XXXP single-chip 4-bit microcomputer.

This cross assembler not only provides many pseudo instructions, control commands, and control data for improving programming efficiency, but it also provides program versatility for changing instruction codes and functions.

FEATURES OF THE CROSS ASSEMBLER

- 3 types of control data
- Instruction codes and functions easily changed
- Catalogs the control data in disk storage
- Constants can also be expressed in non-decimal notations
- Printouts available from the tables and cross-reference lists
- Execution computer: MELCOM 70 (memory capacity more than 24K words, monitor 8DOS)
- Implementation language: FORTRAN IV (parts are written in assembly language)

FEATURES OF THE ASSEMBLY LANGUAGE

- 6 pseudo instructions
- 77 machine instructions
- Decimal numbers can be used to define the constants of the machine instruction operand field.

INPUT/OUTPUT MEDIA

- Source input : Punched cards and magnetic disk
- Control data input : Punched cards and magnetic disk
- Control data command : Punched cards
- Execution command : System typewriter keyboard
- Object output : Magnetic disk
- Output lists : Line printer

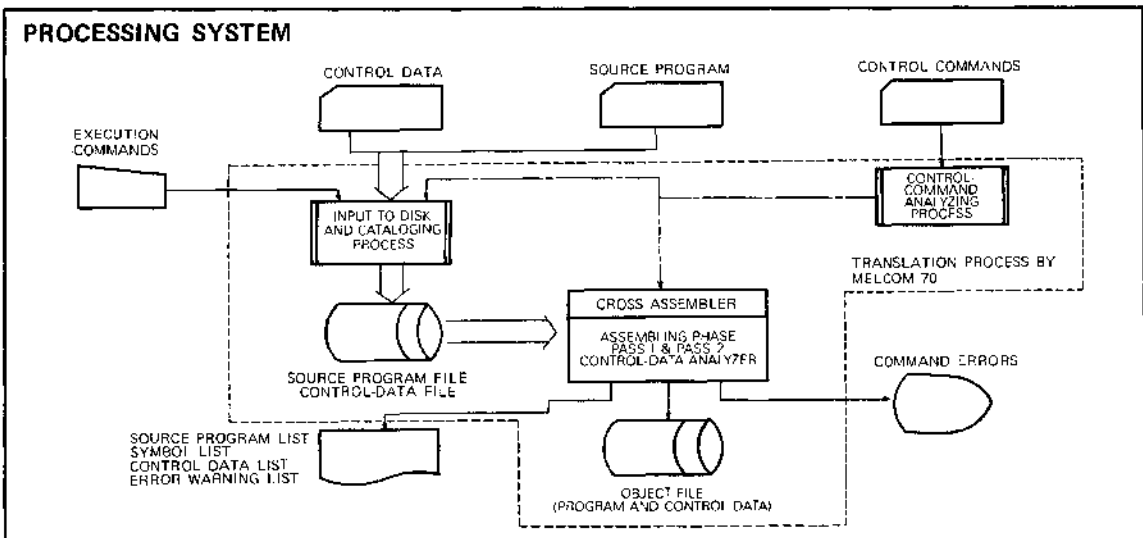

FUNCTION

This cross assembler converts source programs written in the MELPS 42 assembly language to machine instruction codes that are filed in disk storage in the form of binary absolute object codes.

The MELPS 42 cross assembler is a 2-pass translator that provides data and control command analysis along with cataloging functions.

Modifying the instruction code and setting mnemonic tables and numeric tables to constants can easily be accomplished by means of the control data. In this way, programming versatility is provided for changing functions, allowing the user free selection in defining the mnemonics of the machine instructions, etc.

The standard version of the MELPS 42 assembly language has 7 assembler control commands (see Table 1). In addition 6 pseudo instructions (Table 2) can be used in the source language program.

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included
MELPS 42 cross assembler	GBIAS0010	MELPS 42 Cross Assembler Manual GBM-SR 00-31A <03A0>

CROSS ASSEMBLER

This cross assembler facilitates assembly by the use of the control commands shown in Table 1. Basically, it requires only the source program and control commands input by punched cards with control data being utilized only when necessary. All input is stored and filed in disk storage. The control data is processed by the control command analyzing processor, and the symbol table is created in pass 1. This is followed by pass 2, where each instruction is converted to machine language, while control data, labels and the assembly list are printed out as specified by the control commands. On the assembly list, the control commands, sequence numbers, location numbers and addresses are printed out, along with error and warning messages, followed by the ROM page list and the cross-reference list.

OBJECT LANGUAGE

The object file is composed of a name section and a text section.

The name section is filed on sector 0 of the object file and stores overall information such as the total number of instructions in the text section, control data, file name, source program file name, size of a single page and the module name.

The text section contains the data that controlled the conversion of the source program to instruction codes and other related data necessary for execution by the simulator.

ASSEMBLY LANGUAGE

The assembly language that the MELPS 42 cross assembler accepts consists of machine instructions and pseudo instructions.

1. Machine Instructions

There are 77 basic machine instructions. These are converted to their corresponding machine codes and then assembled into an object program. For the mnemonics, instruction codes and their functional descriptions, please refer to the data sheet provided for the M58496-XXXXP single-chip 4-bit microcomputer.

2. Pseudo Instructions

Although the pseudo instructions are written in the source program together with machine instructions, they are not converted to instruction codes but are used to control the assembler. The instruction codes will be written in the ROM.

The assembler-control instructions, numeric symbols defining instructions and list control instructions are among the pseudo instructions.

The pseudo instructions are shown in Table 2.

Table 1 Assembler control commands

Command		Format	Function
Execution start		/// RUN	Starts execution of the cross assembler
Execution end		/// END	Terminates execution of the cross assembler
Input/output function assignment		/// ASMB4, x, y, z	Assignment of assembly execution and control data and assembly listings $x = \begin{pmatrix} A \\ P \end{pmatrix}$ x : Assembly control $y = \begin{pmatrix} L \\ N \end{pmatrix}$ y : Designation of cataloging function $z = \begin{pmatrix} L \\ N \end{pmatrix}$ z : Assembly listing z : Control data listing L : Listing needed N : No listing needed
File assignment control	Control data	/// CDISK, XXXXX	Assignment of the control file name (max. 6 characters)
	Source program	/// SDISK, XXXXX	Assignment of the source program file name (max. 6 characters)
	Object	/// BDISK, XXXXX	Assignment of the object file name (max. 6 characters)
Input/output device assignment		/// INPUT, x, y	Assignment of input device for the control data and source program $x = \begin{pmatrix} C \\ D \\ N \end{pmatrix}$ x : Control data input $y = \begin{pmatrix} C \\ D \\ N \end{pmatrix}$ y : Source program input C : Punched card input D : Disk input N : Control data no input

Table 2 Pseudo instructions

Classification	Mnemonic	Instruction	Function
Assembler control instruction	TTL	Program title declaration	Declares the program title
	PAGE	Program counter paging	Sets the counter to the top address of the next page
	ORG	Program counter setting	Sets the counter to the top address of the program
	END	End declaration	Declares the end of the program
Symbol value equivalence instruction	EGU	Symbol value setting	Sets a numeral value to the specific numeral symbol
List control instruction	EJE	Page eject declaration	Advances the printout form to the next page during output

3. Language Format

The following format should be used in coding programs in this cross assembler.

The single-line statement is composed of the label, instruction, operand, comment, and identification fields. The format of the source statement is fixed as indicated in Fig. 1. Although the constant is usually a decimal number, it may be expressed by hexadecimal notation when defined by pseudo instructions.

An asterisk (*) in the first column of a line indicates that the entire statement is used as a comment field.

The following are valid characters for use in statements:

Alphabets: A~Z

Numerics: 0~9

Special characters: ; = , * / ! & () .

% < > ? (space)

Fig. 1 Source statement format

(1) Label field

The value of the program counter at that time is set to the label. The number of characters used for a label is limited to a maximum of 6, and any of the alphanumeric and special characters specified above can be used. However, an asterisk (*) cannot be used in the first column of the label field.

(2) Instruction field

Mnemonic codes are written in this field, left-justified. For pseudo instructions, any of the mnemonics among the assembler-control instructions, numeric symbol definition instructions and list-control instructions may be used.

(3) Operand field

Parameters of the instruction are specified in this field. This field contains the label, defined symbol, or numerical value. The operand is stated from the 14th column, left-justified.

(4) Comment field

Whenever the operand is followed by more than one space to the end of the statement, the successive columns may be used for comments.

(5) Identification field

The use of this field is optional. Many find it convenient to use this field for a sequential identification card number.

ASSEMBLY LIST FORMAT

A source program prepared and assembled in the format indicated in the preceding paragraph may produce source, symbol table, cross reference, and ROM page list printouts. The format of an assembly list produced as an example is shown in Fig. 2. Please note that pages, locations, and object codes are indicated in hexadecimal notation.

MESSAGE FORMAT

Error and warning messages are printed out on the assembly list. In the case of errors, the message is printed out under the respective statement in the following format.

\$\$\$\$\$ERROR xxx\$

where "x x x" indicates the type of error by a numerical code.

In the case of warnings, the following message is printed between SEQ (sequential number) and LOC (location number):

* Wx * (where "x" indicates the degree of warning)

In addition the total number of errors and warnings are printed on the last line of the assembly list. The cross-reference list, however, will not be produced when any errors are indicated.

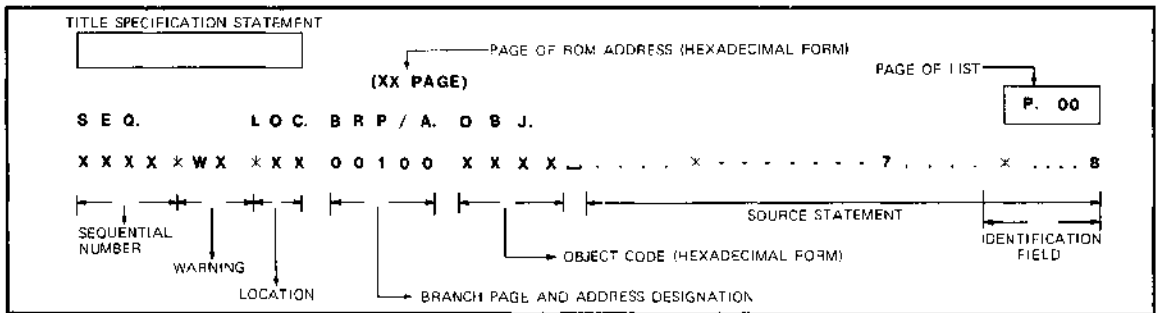

Fig. 2 Assembly list format

Example of an assembly list

An actual example of an assembly list for an assembly made with the MELPS 42 cross assembler is shown in Fig. 3.

SEQ.	LOC=BRP/A.	OBJ.	SOURCE STATEMENT	IDENTIFICATION FIELD
1			ORG D=0	EXAMPLE PROGRAM
2			FILE EXCHANGE	EXAMPLE PROGRAM

30	09	001	TAN 1	
31	0A	008	XAND 0	
32	*WD=06	104	BR LBL5	
33	0C	044	RT	
34			END	

- ① The program name is declared as "EXAMPLE PROGRAM".
- ② It shows that the start of the program was set to page 0 address 0 by means of the program counter setting instruction.
- ③ An asterisk (*) in the first column indicates that the entire statement is a comment.
- ④ Numeric value 13 (decimal number) is assigned to the symbol DIGMAX by means of the symbol value equivalence instruction.
- ⑤ The label XCG02 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 14 address 00.
- ⑥ The label XCG13 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 14 address 01.
- ⑦ The label XCG23 is assigned by means of the BM instruction during the assembly process, and calls the subroutine starting at page 14 address 07.
- ⑧ This whole statement line is used as a comment field.
- ⑨ The numerical value 0 is loaded in register X of the data pointer and 13 (decimal number) in register Y by means of the LXI instruction. As written, the results of this LXI instruction are nullified by the results of the following LXI instruction.
- ⑩ The numerical value 1 is loaded in register X of the data pointer and 13 (decimal number) in register Y by means of the LXI instruction.
- ⑪ The BM instruction in this case assigns the branch address of the label LBL4 to address 02 of page 14.

MITSUBISHI MICROCOMPUTERS MELPS 42 SOFTWARE

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

DESCRIPTION

MELPS 42 PROM writer paper-tape generation programs are used to convert the absolute binary object program generated by the MELPS 42 cross assembler into another format that can be used in a PROM writer. The program is output on paper tape in the new format.

With this program, a binary object program can easily be converted to hexadecimal object format that can be programmed directly into a PROM. It can produce paper tapes that meet the requirements of Takeda Riken's and Minato Electronics' PROM writers.

FEATURES

- Outputs the binary object program in the disk storage to paper tape in hexadecimal format
- Paper-tape output can be partitioned with a simple control command
- May be used in conjunction with the MELPS 42 cross assembler
- Execution computer: MELCOM 70 Minicomputer (memory capacity more than 16K words, monitor BDOS)
- Programming language: FORTRAN IV (parts are written in assembly language)

INPUT/OUTPUT MEDIA

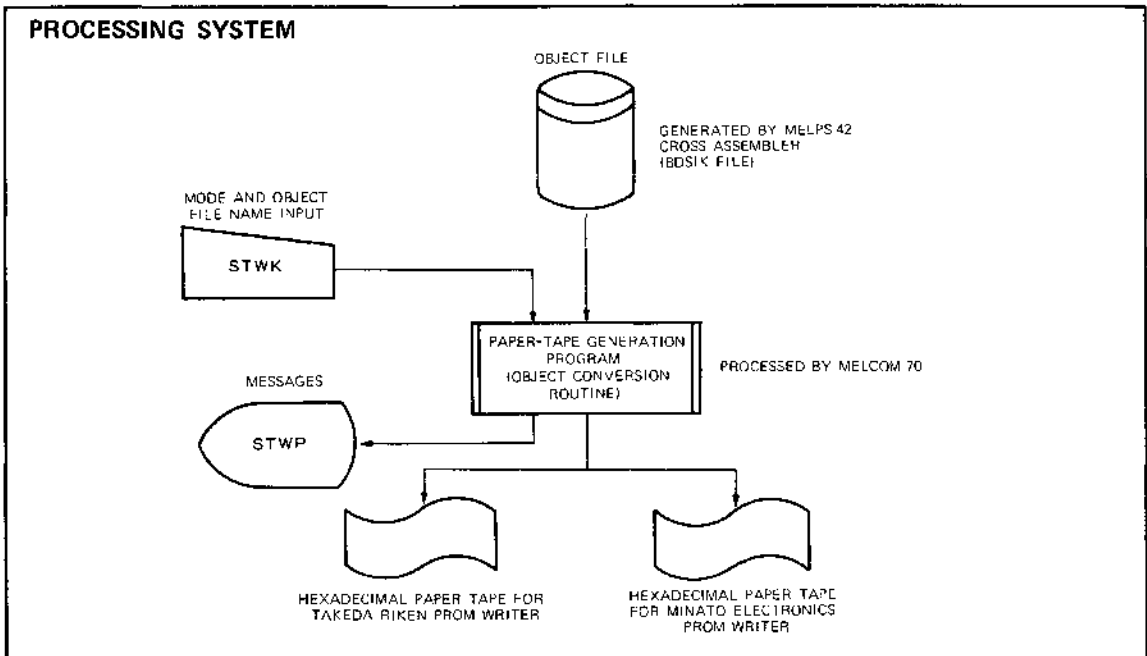

- Input : Cartridge disk storage
- Output : Paper tape (ASCII code, even parity)
- Control command input : Through the keyboard of the system typewriter
- Messages : System typewriter printout

APPLICATIONS

For preparing programs for 1K words X 8-bit EPROMs (M5L2708K, S), etc., which are to be programmed by PROM writers supplied by Takeda Riken or Minato Electronics.

FUNCTION

This program is used for converting the absolute binary object format programs generated by the MELPS 42 cross assembler to hexadecimal object format compatible with the PROM writers manufactured by Takeda Riken (T310) and Minato Electronics (model 1830 and 1802). The paper-tape output is partitioned in accordance with PROM capacity (number of bytes).

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included
MELPS 42 paper-tape generation program for PROM writer	GBISP 0006	MELPS 42 paper-tape generation program for PROM writer manual GBM-SR 00-33A <03A0>

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

PROGRAM PROCESSING

The program has conversion routines for Takeda Riken's and Minato Electronics' PROM writers. Select T₁ mode (for Takeda Riken's PROM writer) or M₁ mode (for Minato Electronics' PROM writer) through the system typewriter keyboard. Then the object program is converted to paper tape compatible with the selected PROM writer. When a (BDISK file) file name is called, a paper tape is output for the PROM writer. When a number of programs are to be converted from the same file, successive calls can be made until all the programs are converted. Termination of the job is directed with the E command, and control is then returned to the monitor.

The object file consists of name and text segments. The data to be converted is contained in the text segment. Instruction codes, stored after sector 1 of the disk, that corresponds to machine instructions are converted to hexadecimal codes and output to paper tape.

Example of Hexadecimal Paper-Tape Format

This program can generate paper tapes for Takeda Riken's PROM writer or Minato Electronics' PROM writer. Examples of both formats are shown in Figs. 1 and 2.

Example of Object Conversion

The program at present can output 1K-word units of paper tape up to a total of 4K words. An example is shown in Fig. 3.

Error Processing

When an error is encountered during object conversion, a message will be printed out in the following format:

\$\$\$\$\$\$\$ xxx\$

where, XXX indicates the error code.

Fig. 3 Example of object conversion

Fig. 2 Example of hexadecimal paper-tape format of Minato Electronics

CROSS ASSEMBLER

DESCRIPTION

The MELPS 8-48 cross assembler has been prepared for aiding the development of application programs suitable for equipment using the M5L8041-XXXP, M5L8048-XXXP and M5L8049-XXXP MITSUBISHI single-chip 8-bit micro-computers.

This cross assembler allows conversion of source programs written in the MELPS 8-48 assembler language by using a host computer into objects in the MELPS 8 binary language.

The assembler language has machine pseudo and macro instructions. The full equipment of pseudo instructions and control commands ensures high programming and debugging efficiency. Coding can be carried out in a free format.

FEATURES OF THE CROSS ASSEMBLER

- Flexibility in assembler-language changing
- Various input/output media available
- Free-format coding
- A symbol table is output as part of the object code.
- Executed on a MELCOM 70 minicomputer (with 24 K words of memory capacity or more, BDOS monitor)
- FORTRAN IV programming language (with some assembler language)

FEATURES OF THE ASSEMBLER LANGUAGE

- 10 pseudo instructions
- 6 Macro instructions
- Numerical formula used
- Character constants and strings used

- In addition to decimal notation as the standard format, binary, octal and hexadecimal notations can be used
- Machine-instruction compatibility with Intel Corporation's cross assembler

INPUT/OUTPUT MEDIA

- Source input: Punched cards, punched tapes, magnetic tapes, magnetic disks
- Control-command input: Punched cards
- Object code output : Magnetic disk

FUNCTION

This cross assembler converts source programs written in the MELPS 8-48 assembler language to machine-instruction codes, which are output as absolute objects.

The MELPS 8-48 cross assembler functions in two phases: control-command analyzing phase and assembly phase (intermediate-language-generation and listing phases).

The assembly-control commands listed in Table 1 are available. They cover use for execution start-up, termination assignment, I/O assignment, file assignment, link control and relocation assignment.

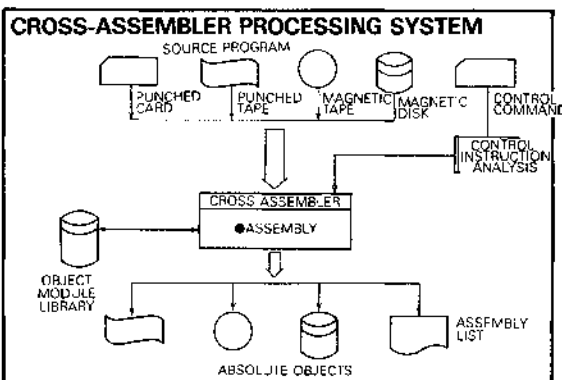

This cross assembler permits the use of the machine-instruction codes applicable to Intel's Models 8041, 8048 and 8049 and of the 10 pseudo instructions listed in Table 3.

CROSS ASSEMBLER

With various control commands and pseudo instructions, the MELPS 8-48 cross assembler ensures easy program debugging.

Source programs can be input by means of punched cards, punched tapes, magnetic tapes, and magnetic disks. When the control commands are read in, parameters to control assembly processing are generated by designating the assembly-control command.

In the assembly-processing stage, the source program is read in, and the intermediate language is generated in phase 1. This intermediate language and the source program are stored in the disk, and the absolute object is then produced. That can be output on punched tape, magnetic tape, magnetic disk or other media as specified.

PROGRAM ORDERING INFORMATION

Program name	Ordering No	Program and software manuals included
MELPS 8-48 cross assembler	GC1AS0200	Source program MELPS 8-48 Assembler Language Manual GCM-SR00-01A MELPS 8-48 Cross-Assembler Manual GCM-SR00-02A MELPS 8-48 Cross-Assembler Operating Manual GCM-SR00-03A

CROSS-ASSEMBLER OBJECT LANGUAGE

The objects produced by this cross assembler basically consist of name, symbol and text sections. An end section is placed at the rear end of an object. Fig. 1 shows the object-module configuration. Each name section is placed at the head of each object module, and serves for recording information such as the name of the object module, ROM/RAM information, and the number of symbols. The symbol sections are used to record information concerning the numeric symbols (labels) written in the source program. The text sections have data on the conversion of the source program to the instruction code. The end section specifies the termination of one object program.

ASSEMBLY LANGUAGE

Machine instructions pseudo and macro instructions can be used in the MELPS 8-48 cross assembler.

1. Machine Instructions

A total of 96 basic machine instructions are available. They are converted to their corresponding machine codes and then assembled into an object program. A classification of these instructions is given in Table 2.

For the mnemonics, instruction codes and their functions, please refer to the data sheet provided for the single-chip 8-bit microcomputers M5L 8041-XXXP, M5L8048-XXXP and M5L8049-XXXP.

2. Pseudo Instructions

Although the pseudo instructions are written in the source program together with machine instructions, they control the cross-assembler execution during assembly processing. That is, they are not converted into instruction codes to be written in the ROM but are used to control the assembler.

These instructions include those used for assembly control, numeric-symbol and memory-content definition, area securing, and list control. Table 3 lists the pseudo instructions.

3. Macro Instructions

These instructions consist of groups of several machine language instructions or simple instructions used to specify parameters. They consist of the 6 instructions MACRO, LOCAL, REPT, IRP, IRPC, and ENDM.

Fig. 1 Object-module configuration

Table 1 Control Commands and their Functions

Command	Format	Function
Execution-start control	///RUN	Starts execution of the cross assembler in accordance with the command designated.
Execution-end control	///END	Terminates execution of the cross assembler
Mode designation	///ASMB48, X, Y, Z	Specification of the processor for which assembly is to be performed and the ROM size MM: Mode designation MM = 48 8048 mode (including 8049) MM = 41 8041 mode X: Maximum ROM size designation X = 1 ~ 4 for 1 ~ 4K byte
Output option designation	///OPTIN, XX, XX	Selection of assembly listing, reference listing, and symbol listing for the object code including number of characters per line (same as ///OPTIN, LS, XL when abbreviated) XX: Output option selection XX = LS Assembly listing output XX = XL Reference listing output XX = SO Symbol object file output XX = PL 80 characters per line (132 maximum when no specifications made)
Source input device designation	///INPUT, X((Y))	Source input device designation (same as ///INPUT, C when abbreviated) X: Source program input device X = C Paper card X = D Magnetic disk X = P Paper tape X = M Magnetic tape Y: Magnetic tape character code (abbreviated as ASCII code) Y = A ASCII code Y = E EBCDEC code
File designation	///MDISK, XXXXX	Macro source working file name (maximum of 5 characters)
	///SDISK, XXXXX	Source program file name (maximum of 5 characters)
	///BDISK, XXXXX	Absolute object program file name (maximum of 5 characters)

4. Language Format

The following free format should be used in coding programs in this cross assembler.

The single-line statement of the source program is composed of label, instruction, operand, comment, and identification fields. The format of the source statement is free, as shown in Fig. 2, allowing easy coding and punching without the fear of dislocated columns. The following characters can be used in statements.

- Alphanumeric A~Z
- Numerics 0~9
- Special Characters ; , = , ▼ @ \$ + - * / ! & () .
 # % < > ? (blank)

Table 2 A Classification of Machine Instructions

Function classification	Functions of the instruction
Data-transfer instruction	Direct data setting Between registers Between memories and registers
Adding logic operation	Addition, AND, OR, EXOR logic operations Accumulator increase and decrease, clear and rotation shift, decimal correction
Register increase and decrease	Register increment, register decrement data-memory increment
Flag control	Carry clear, carry correction, clear-flag 0, 1 and flag 0, 1 correction
Subroutine control	Subroutine jump, return from subroutine return and status restore
Interruption control	External interruption possible External interruption prohibited Register-bank and memory-bank selection Clock-output enable
Input/output control	Between port and accumulator Port and immediate data OR and AND Between bus and accumulator Bus and immediate data OR and AND Between expander port and accumulator Expander-port and accumulator OR and AND
Jump instructions	Unconditional jump Indirect jump Register decrement skip Jump by carry 0, 1 Jump by accumulator 0 or non zero Jump by T0 = 0 or 1 Jump by T1 = 0 or 1 Jump by F0 = 1 or F1 = 1 Jump at the time of timer flag Jump at the time of IKT = 0 Jump by accumulator bit
Timer-counter control	Timer/counter read Timer/counter load Timer start, counter start Timer/counter stop Timer/counter interruption allowed Timer/counter interruption prohibited
Others	No operations

Fig. 2 Source-Statement Format

1. Label field

The value of the program counter at that time is set to the label. The number of characters used for a label is limited to a maximum of 6. The character : is placed at the back of this field. However, a semicolon (;) cannot be used in the first column of the label field.

2. Instruction field

Mnemonic codes of the machine and pseudo instructions are written in this field.

3. Operand field

Arguments (formula, data, parameters, etc.) for the instructions are written in this field. The label, defined symbol, formula, or numerical value is contained within it.

4. Comment field

This field is used for writing notes for the statement and is not converted to an object. Placing a semicolon (;) in the first column makes the whole statement a comment. When a semicolon (;) is placed halfway through the statement, the section after the semicolon is regarded as a comment.

Table 3 Pseudo Instructions

Classification	Item	Mnemonic	Instruction
Assembler-control instructions		NAM	Program name declaration instruction
		ORG	Program-counter setting instruction
		EOT	
		END	End-declaration instruction
Numeric-symbol and memory-content definition instructions		EQU	Numeric-symbol definition instruction
		SET	
		DB	Data-setting instruction
Region-securing instruction		DW	Address-setting instruction
		DS	Region-securing instruction
List control instruction		EJE	Page-feed declaration instruction

Table 4 Macro Instructions

Instruction	Description
Macro	Macro symbol definition instruction
ENDM	End instruction for a macro definition
LOCAL	Symbol replacement instruction
REPT	Repeat instruction
IRP	Infinite repeat instruction
IRPC	Direct number infinite repeat instruction

Table 5 Expression Formats for Numeric Values, Character Constants and Formulae

	Item	Expression
Numeric values	Binary	—
	Octal	nQ
	Decimal	n
	Hexadecimal	nH
Character constants	A (1-byte)	'A'
	AB (2-byte)	'AB'
	A'B (3-byte)	'A 'B'
Formulae	4 Arithmetic-rule operations	+, -, *, /
	Logic formula	—
Others	Program counter	\$

5. Identification field

The use of this field is optional. Many operators find it convenient to use it for the sequential identification card number.

CODING FORMAT

Programs written in the MELPS 8-48 assembler language can be coded in free formats.

General formats for using the control commands and program coding for this cross assembler are described below, together with a citation of a few examples.

1. Control Commands

1. Control-command general format

LABEL	STATEMENT AND
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33	/// XYZ, P1, P2, P3,

XYZ : Assembly-control-command symbols
 P1, P2, P3 : Assembly-control parameters

2. Example of assembly control

LABEL	STATEMENT AND
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33	/// ASM48, L, C, N
	/// SDISK, XXXXX
	/// RUN

The source program is input through the card reader, and an assembly list is output.

2. MELPS 8/48 Assembler-Language Program

1. General format of program coding

LABEL	STATEMENT AND COMMENT	IDENTIFICATION SEQUENCE
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22	LABEL: MNEM OPE : COMM	72 73 74 75 76 77 78 79 80
		SEQ 000
		010
		020

LABEL: A colon (:) is always placed behind the label name
 MNEM Instruction symbol (mnemonic)
 OPE Operand (:) or more blanks must always be included
 :COMM Comment (A semicolon (;) is always placed at the head)
 SEQ Sequential No. (columns 73-80)

2. Example of program

LABEL	STATEMENT AND COMMENT
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33	/// *** PROGRAM EXAMPLE ***
	/// *DECIMAL ADDITION
	NAM EXAM
	ROM
	X EQU 10
	Y EQU 50
	CNT EQU 10
	ORG 500H
	MOV R0, #X
	MOV R1, #Y
	MOV R2, #CNT
	CLR C : CLEAR CARRY
BR:	MOV A, @R0
	ADDC A, @R1
	DA A
	MOV @R0, A
	INC R0
	INC R1
	DJNZ R2, BR
	OUTL P1, A
	END

- ① The lines having a semicolon (:) in the first column are regarded as comments.
- ② The program name is declared as "EXAM" by the NAM pseudo instruction.
- ③ The following lines are regarded as a ROM region.
- ④ The decimal numbers 10, 50, and 10 are assigned respectively to symbols X, Y, and CNT.
- ⑤ The program start address is address 500 in hexadecimal notation.
- ⑥ The values #X, #Y, and #CNT are respectively put into registers R0, R1, and R2.
- ⑦ The carry is cleared.
- ⑧ The contents of label BR memory at R0 (at the address to be jumped to: the colon (:)) shows a label) are put into accumulator A.
- ⑨ The contents of the carry and data memory at R1 are added to each other, and put into the accumulator.
- ⑩ The accumulator contents are decimal-corrected.
- ⑪ The accumulator contents (decimal-corrected results of the addition) are put into the memory data at R0.
- ⑫ The contents of registers R0 and R1 are incremented.
- ⑬ Register R2 is decremented and if the contents are not 0 (zero), branching to BR follows. If 0, execution proceeds to next step.
- ⑭ The contents of the accumulator are output in port 1.
- ⑮ The end of program is declared.

MITSUBISHI MICROCOMPUTERS MELPS 8-48 SOFTWARE

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

DESCRIPTION

This program is used to convert absolute binary object formatted programs, which are produced by the MELPS 8-48 cross assembler, into other language formats and then produce a paper tape that can be used as input for a PROM writer.

The functional configuration of this program offers automatic conversion of object programs from one format to another format as well as comparison processing. In addition, it provides extensions suitable to various applications.

FEATURES

- It selectively produces partitioned, punched paper tapes with simple control commands.
- It converts MELPS 8 binary object programs stored on disks into various hexadecimal formats on paper tape.
- It converts various hexadecimal-format paper tapes into MELPS 8 hexadecimal format.
- Comparison-matching control functions for MELPS 8 hexadecimal format paper tape as well as other formats.
- Output of various block sizes as specified by the block size (i.e., paper-tape partition) parameter.
- Sorting capability to put files in address sequence.
- Execution computer: MELCOM 70 minicomputer (memory capacity: more than 24K-words; program: about 5,000 steps).
- Implementation language: FORTRAN IV (parts are written in assembler language).

INPUT/OUTPUT MEDIA

- Conversion of MELPS 8 binary to hexadecimal paper tapes
 Input: cartridge disk units
 Output: paper tapes (even-parity ASCII code)

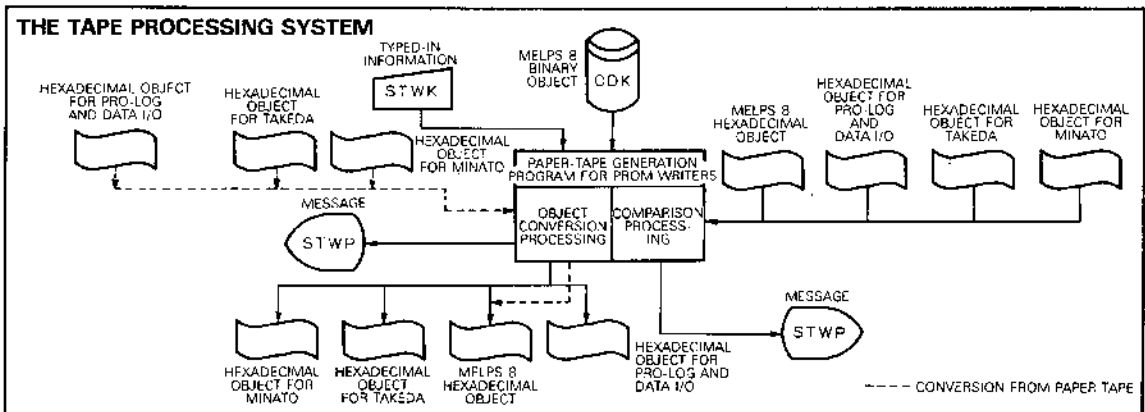

- Conversion of other hexadecimal paper tapes to MELPS 8 hexadecimal paper tapes
 Input: paper tapes in other hexadecimal format (even-parity ASCII code)
 Output: paper tapes in MELPS 8 hexadecimal format (even-parity ASCII code)
- Comparison of MELPS 8 hexadecimal with other hexadecimal paper-tape formats and self comparison
 Input: paper tapes (even-parity ASCII code)
 Output: printed on system typewriter
- Control-command input
 Through system-typewriter keyboard

APPLICATIONS

Programs are applicable to the M5L2708K and -S (1K-word by 8-bit), M5L2716K (2K-word by 8-bit), and other similar ROMs when prepared by a PROM writer produced by Takeda Riken, Minato Electronics, Pro-log, and Data I/O.

FUNCTION

This program converts absolute binary object programs (abbreviated MELPS 8 binary), created in the disk area by the MELPS 8-48 cross assembler, into hexadecimal object programs. These hexadecimal object programs can be used to program PROMs on PROM writers produced by Takeda Riken (T310), Minato Electronics (Type 1830), Pro-log Ltd. (Series 90), and Data I/O (abbreviated hereafter as Takeda, Minato, Pro-log, and Data I/O). This program also converts absolute binary object programs into the MELPS 8 hexadecimal format and creates paper tapes with blocks of suitable size. The program can also convert paper tapes of Takeda, Minato, Pro-log and Data I/O into MELPS 8 hexadecimal format and compare the object paper tapes.

Fig. 1 Medium conversion

DESCRIPTION

This cross compiler is supplied on magnetic tape to users of MELPS 8/85 CPUs. It is written in FORTRAN IV for execution of the MELCOM 7000 and can be easily run on other host computers with a FORTRAN IV compiler.

The PL/1 μ language gives MELPS 8/85 microcomputer users the same advantages that users of mini and large computer systems have with the high level programming languages that are currently available. It has the same language structure as PL/1 and has been designed to take advantage of the system architecture of the microprocessor. System designers can use PL/1 μ to quickly and easily implement new applications. In addition, programs written in PL/1 μ are self-documenting; so they can be easily changed and maintained. PL/1 μ is recognized as one of the best suited languages for programming microcomputer applications because the user retains the control and efficiency of an assembly language.

FEATURES

Of the PL/1 μ Cross Compiler

- Conditional compile with preprocessor
- Inline assembly
- Source program editing at compile time

- Assignment of programs to ROM or RAM regions
- Generates a relocatable object program
- Linking function
- Easily understood error messages
- Flexibility in input/output media
- Execution computer: MELCOM 7000 (UTS/VS)
- Implementation computer: MELPS 8/85 microcomputer
- Implementation language: FORTRAN IV

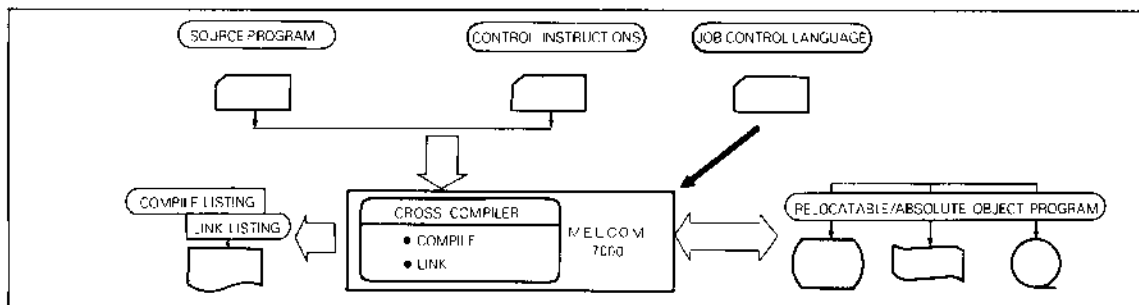

Of the PL/1 μ Language

- Bit operations
- Three-level structure
- One-dimensional arrays
- Allocation of variables to specified absolute addresses
- Multi-entry function
- Interrupt function

FUNCTION

PL/1 μ has a preprocessor that allows user to modify programs under development at compile time through the use of conditional compile, exchange, exclude and include functions. A program is divided into fixed and variable segments, and these segments are automatically assigned to the appropriate memory (RAM or ROM) during compiling. The link editor can link up to 20 object programs (files).

Fig. 1 PL/1 μ cross compiler processing system

PROGRAM ORDERING INFORMATION

OPERATIONS

Users of PL/1 μ will find it flexible and easy to use because of its many special features such as the preprocessor, the link editor and the memory manager.

The preprocessor has 10 statements that can be used at compile time to edit a PL/1 μ source program. These can generate, exchange or delete program text, as well as modify definitions, references and macro instructions.

The link editor is able to link up to 20 object programs that have been generated by MELPS 8/85 software. The memory manager divides PL/1 μ programs into fixed and variable segments and assigns the segments to the appropriate memory. A fixed segment is assigned to a non-write area (ROM) while a variable segment is assigned to a write area (RAM) during compiling; at the same time, the starting address of each segment is recorded for linking (see Fig. 2).

Fig. 2 Linking of two programs

PL/1 μ LANGUAGE

The PL/1 μ language is a subset of the popular PL/I language with the addition of special functions to take advantage of the microprocessor's architecture. The main features of the PL/1 μ language are as follows:

Easy to Read and Write

The statements are written in free format and are independent of columns and lines. The statements are formatted in natural language. It is easy to express, read and understand the programs. Programs written in PL/1 μ are self-documenting.

Block-Structured Language

Programs written in PL/1 μ consist of one or more blocks that are called procedures. A procedure (block) can be thought of as a subroutine. The block structure of PL/1 μ simplifies modular programming. Each procedure can be conceptually simple and therefore easy to formulate and debug.

BASIC LANGUAGE SPECIFICATIONS

1. Statements

The basic unit of the PL/1 μ language is called a statement. A procedure (block) is composed of one or more statements, and a program is composed of one or more

procedures. The statements are categorized as follows:

- | | |
|------------------------------------|--|
| Statements – Procedure definition: | PROCEDURE statement |
| – Declaration: | DECLARATIVE statement |
| – Condition: | IF statement |
| – Non-condition: | Assignment statement, DO group, and others |

The last character of a statement must be a semicolon (;). A statement may have a label (identifier) that is the name of the statement.

Example **EXAMPLE: X = Y + Z;**

2. Identifiers

PL/1 μ identifiers are used to name variables, procedures, macro instructions and statements. An identifier may be up to 31 characters in length, and the first character must be an @, ? or alphabetic (A~Z) character. The remaining 30 characters may be alphanumeric (A~Z, 0~9), @ or ?.

Reserved words may not be used as identifiers in the PL/1 μ language.

LANGUAGE SPECIFICATIONS

Item	Specification
Character set:	65-character set Alphabetic: A-Z , Currency Unit (\$), Numeric: 0-9 Special: = + - * / , . : ; < > % ' () ^ ? (blank)
Comments	/ * * /
Identifiers	3' or less alphanumeric characters
Reserved words	IF DO GO TO OR BY ON EOF END XOR AND NOT MOD HALT THEN ELSE CASE CALL GOTO DATA BYTE PLUS MAIN LABEL BASED MINUS WHILE ENTRY ENABLE RETURN BINARY DISABLE DECLARE ADDRESS INITIAL ALIGNED OPTIONS INTERNAL EXTERNAL RELOCATE GENERATE INTERRUPT PROCEDURE LITERALLY UNALIGNED
Constant types	Binary, octal, decimal, hexadecimal character string

MITSUBISHI MICROCOMPUTERS MELPS 8/85 SOFTWARE

SIMULATOR

DESCRIPTION

A pseudo CPU and a pseudo memory are modeled in the host computer by the simulator, and programs in the pseudo memory are executed by the pseudo CPU to debug and test programs.

The simulator contains a powerful set of 26 control commands for efficient program debugging.

FEATURES

- Set of 26 powerful control commands
- Batch and conversational processing
- Symbolic addressing
- Execution time calculations
- Intermediate results saved in specified format
- Binary, octal, decimal and hexadecimal numbers are selectable
- Assignment of program segments to ROM or RAM region
- Memory protection
- Interrupt function
- Flexibility in input/output media
- Continuous processing of input/output data
- Execution minicomputer: MELCOM 70 (memory capacity more than 24K words, monitor BDOS)

- Programming language: FORTRAN IV (parts are written in assembly language)

FUNCTION

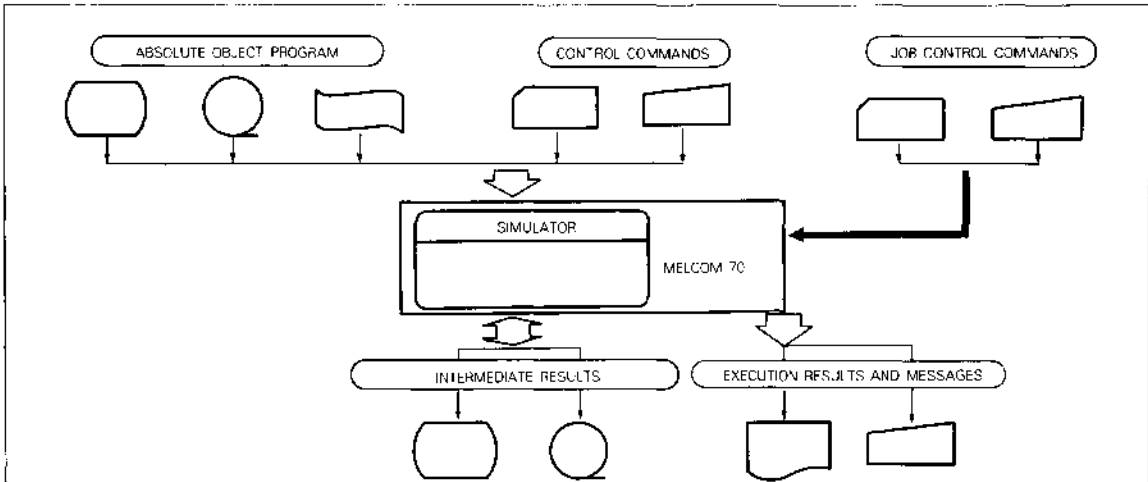

The trace command function assigns a specific trace region so that it traces only the specified program steps. Execution of the simulation can be halted by a breakpoint that can be assigned to any location. Program debugging efficiency can be expected to increase by the use of these functions.

Memory protect and ROM regions are simulated. This means the simulator will not allow writing in a ROM region and will not allow either reading or writing in a memory protect region. Therefore, the program under simulation is completely simulated, including the state of the memory in the object computer system.

Input/output media

- Object program input: Paper tape, magnetic tape and magnetic disk
- Control command input: Punched card and keyboard
- Simulation intermediate results output: Magnetic tape and magnetic disk
- Simulation result output: List
- Input/output data: Punched card, keyboard, paper tape and magnetic tape

CROSS ASSEMBLER FUNCTIONS

The control commands and pseudo instructions in this cross assembler give the user flexibility and improve the efficiency of programming. The cross assembler allows linking, multi-assembly and conditional assembly.

The control commands are shown in Table 1, and the features and their limitations are shown in Table 2.

Table 1 List of control commands

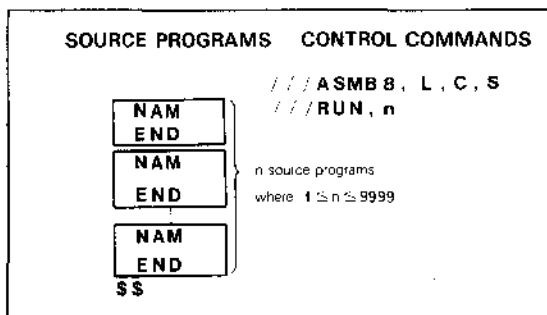

Classification	Control command name	Mnemonic
Assembler control	Execution start	RUN
	End	END
Execution control	Input/output assignment	ASMB8
	Block assignment	BLOCK
		SDISK
	File assignment	ODISK
		BDISK
Link control command	Link assignment	LINKG
	Link location assignment	LKLOC

Table 2 Cross assembler features and their limitations

Features	Limitations
Relocatable object programs	
Link editor	Maximum 20 programs on the disk
Program segmented to non write area (ROM) and write area (RAM)	
Multi-assembly	Maximum 9999 programs
Conditional assembly	Maximum 20 blocks
Flexibility in I/O media selection	Card, disk, paper tape, magnetic tape

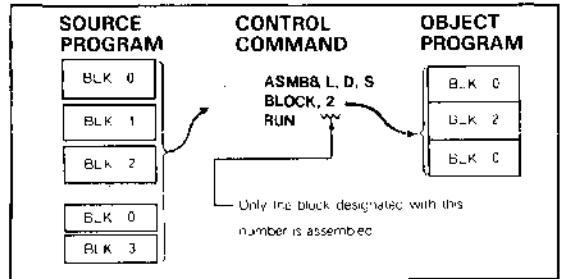

1. Multi-Assembly

Many programs can be batch-assembled in one run.

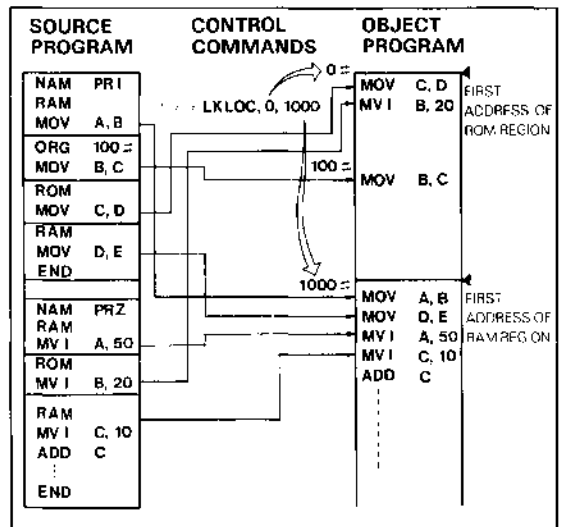

2. Conditional Assembly

Only the designated blocks of a source program are assembled.

3. Linking of ROM/RAM Regions

ROM and RAM regions are linked separately.

CROSS-ASSEMBLER OBJECT PROGRAM

The cross-assembler object program is composed of many object modules, and each module is composed of a name, a symbolic part and a text part. A final part ends each object program.

The symbolic part contains the symbolic name corresponding to symbols. It is possible to program using symbolic names because each module contains a symbolic part.

The object is composed of an 8-bit binary code, and one byte of the instruction code is expressed with one character (8 bits).

Fig.1 Structure of object modules within an object program

ASSEMBLY LANGUAGE FUNCTIONS

The assembly language consists of mnemonic instructions (each corresponding to a machine language instruction), pseudo instructions and macro instructions.

Pseudo instructions are executed by the cross assembler when a source program is being assembled, and they modify the object program. Macro instructions are converted to small segments of machine instructions that are then inserted in the object program. These inserted segments execute the functions of the macro instruction.

Algebraic expressions, alphanumeric constants, character strings, octal numbers, decimal numbers, hexadecimal numbers and symbols may be used as an operand in instructions.

1. Machine Instructions

There are 78 basic machine instructions. These are converted to their corresponding machine language instructions and then inserted in the object program.

A summary of the machine instructions is given in Table 3.

Table 3 Summary of machine instructions

Classification	Instruction functions
Data transfer instructions	Direct data set Between registers Between memory and registers
Addition, subtraction, logical operations and compare instructions	Addition, subtraction, comparing and logical operations using the accumulator together with registers, memory or carry flag
Increment and decrement instructions	Registers, register pairs and memory incremented or decremented
Circulate and shift instructions	Circulate or shift the accumulator's contents
Accumulator adjust instructions	Complement, decimal adjust
Carry instructions	Complement, set
Jump instructions	Unconditional jump Conditional jump
Subroutine call instructions	Unconditional subroutine call Conditional subroutine call
Return instructions	Unconditional return Conditional return
Input/output control instructions	Input and output control
Interrupt control instructions	Enable interrupts Disable interrupts
Stack operation instructions	Saves the contents of registers Restores the contents of registers
Others	CPU halt No operation

2. Pseudo instructions

Pseudo instructions control the execution of the cross assembler while source programs are being assembled. They are not assembled as instructions in the object programs. As shown in Table 4, there are 13 pseudo instructions.

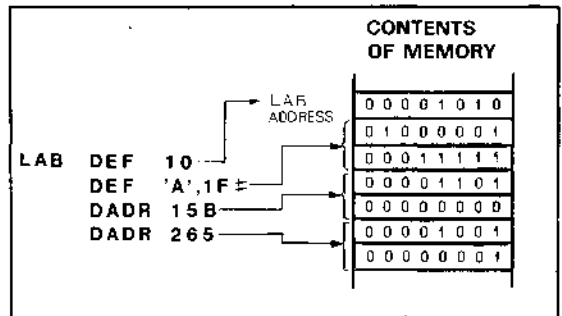

Table 4 List of pseudo instructions

Classification	Mnemonic symbol	Name
Assembler control instructions	NAM	Program name declaration
	ORG	Program counter setting
	ROM	ROM region declaration
	RAM	RAM region declaration
	BLK	Block declaration
	END	End declaration
Link symbol assignment instructions	ENT	Entry name declaration
	EXT	External reference symbol declaration
Memory contents definition instructions	EQU	Value symbol setting
	DEF*	Data setting
	DADR*	Address setting
Storage allocation instructions	BSS**	Storage allocation
List control instructions	EJE	Page eject declaration

*DEF and DADR pseudo instructions set the data or the address in the memory location where the instruction is. See Fig. 2

**BSS pseudo instruction sets the program counter to the value of the operand.

Fig. 2 Example of DEF and DADR pseudo instructions

3. Macro Instructions

Macro instructions are converted to object program segments in machine language that executes the macro instruction functions. The following two macro instructions are included in this cross assembler.

Table 5 Macro instructions

Instructions	Name	Corresponding statement
GET i, j	Data input instruction	IN n
PUT i, j	Data output instruction	OUT n

MITSUBISHI MICROCOMPUTERS MELPS 8/85 SOFTWARE

CROSS ASSEMBLER

DESCRIPTION

This cross assembler is used to convert source programs in assembly language to object programs in MELPS 8/85 format (8-bit binary format) on a host computer. The assembly language consists of mnemonic instructions (each mnemonic instruction corresponds to a machine language instruction), pseudo instructions and macro instructions. It is obvious that the assembly language makes programming and modification of programs easy. The pseudo instructions and control commands in this cross assembler give the user flexibility and improve programming efficiency.

FEATURES

Of the Cross Assembler

- Generates a relocatable object program
- Linking function
- Multi-assembly
- Conditional assembly
- Flexibility in input/output media
- Output of symbolic table of the object program
- Execution computer: MELCOM 70 (memory capacity more than 24K words, monitor BDOS)

- Implementation language: FORTRAN IV (parts are written in assembly language)

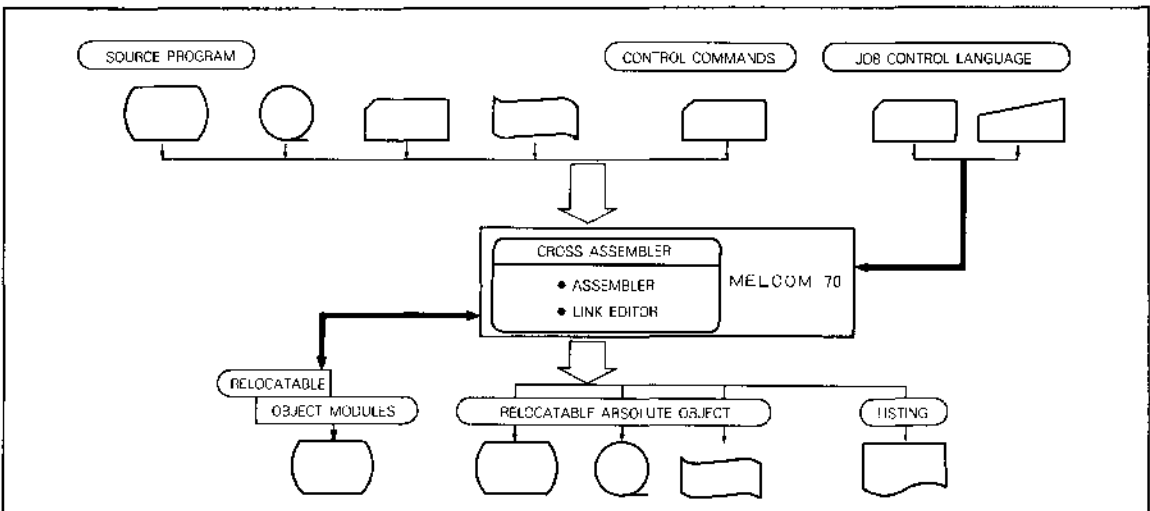

Of the Assembly Language

- 13 pseudo instructions
- Algebraic expressions
- Character constants and strings
- Octal, decimal and hexadecimal numbers
- The mnemonic codes of the machine instructions are the same as Intel's

INPUT/OUTPUT MEDIA

- Source input: Punched card, paper tape, magnetic tape and magnetic disk
- Object input: Magnetic disk
- Control command input: Punched card
- Object output: Paper tape, magnetic tape and magnetic disk

METHOD OF CODING CONTROL COMMANDS

The input formats for control commands are shown in Fig. 1.

Fig. 1 Input formats for control commands

Column no.	1					72	73	80
Contents	Blank	Command	Blank	Parameter list	Blank	Comment	Sequence number	
No. of columns	1 or more columns	The number of characters in the command	1 or more columns	The number of characters in the parameter list	1 or more columns	Free	8 columns	
Remarks	The command, parameter list and comment must be less than 73 columns						Not required if the command is typed in from the system typewriter	

CONTROL COMMANDS

The simulator includes 26 control commands as shown in Table 1.

Table 1 List of control commands and their functions

Functions	Item	Control commands		Comments
		Action	Mnemonic command	
Simulator control commands	Start	Start simulation	<u>START</u>	Starts simulation and designates the input unit for control commands.
		Reinitialize	<u>REINIT</u>	Sets the state to the same state it was after the START command execution was completed.
	End	End simulation	<u>END</u>	Returns to the monitor when executed during simulation.
		Program loading or saving intermediate results	Load object program Save intermediate results	<u>LOAD</u> <u>SAVE</u>
	Changing control command input unit	Changes to card reader	<u>BATCH</u>	The command input unit is changed to the card reader.
Changes to system typewriter		<u>TYPE</u>	The command input unit is changed to the system typewriter.	
Executive control commands	Start	Starts execution of the object program	<u>GO</u>	The stop point can be designated by either an address or the number of instructions to be executed.
		Starts execution of the object program	<u>RUN</u>	Continuous execution until a HLT instruction is encountered.
	Stop	Assigns a breakpoint	<u>BREAK</u>	A breakpoint is assigned by an address or a range.
		Releases an assigned breakpoint	<u>NOBREAK</u>	A breakpoint assigned is released.
		Steps	<u>STEP</u>	Breakpoints are assigned after every specified number of machine instructions.
	Assigning memory regions	Assigns a ROM region	<u>ROM</u>	It is declared that region assigned with this command is the ROM region.
		Releases an assigned ROM region	<u>NOROM</u>	The assigned ROM region is released.
		Assigns a memory protection region	<u>PROT</u>	A memory protect (unaccessible) region is assigned.
	Trace	Releases an assigned memory protect region	<u>NOPTOT</u>	An assigned memory protect region is released.
		Assigns a trace region	<u>TRACE</u>	Printing out the contents of registers, the program counter and flip flops along with the executed instruction codes while executing the instructions in a trace region.
		Releases an assigned trace region	<u>NOTRACE</u>	The assigned trace region is released.
	Set data		<u>SET</u>	Registers, stack pointers, program counter, flag flip flops, I/O ports and the contents of memory are set.
	Interrupt		<u>INTER</u>	If interrupt is enabled, within 3 byte instruction associated with this command is executed.
Counts the number of cycles		<u>TIME</u>	Counts the total number of cycles of the machine instructions executed before this command is encountered.	
Assigns a base		<u>BASE</u>	A base for printing is assigned.	
Printing out	Prints out	<u>DISPLAY</u>	The contents of registers, stack pointers, program counter, flag flip flops, I/O ports and memory are printed according to the assigned base.	
Conversion of values		<u>CONV</u>	The current program counter or the assigned value is printed out in binary, octal, decimal or hexadecimal.	
I/O commands	Input/output simulation	Input simulated	<u>IP</u>	Defines an input string for a machine instruction IN.
		Output simulated	<u>OP</u>	Defines an output string for a machine instruction OUT.

Note 1: The underlined part of the mnemonic command can be used as a short mnemonic.
2: The control command 'START' is the first command, and its input unit must be the card reader.

EXAMPLE OF SIMULATION

The program shown in Fig. 2 is simulated using the control command in the sequence shown in Table 4. The program in Fig. 2 is named 'CON102'. It converts a decimal integer (0~65,535) to a binary number.

The decimal number to be converted is stored in addresses DED1~DED5 in ASCII code, and the converted result is stored in addresses BID and BID+1 (see Table 2). Further, if characters other than 0~9 are found in addresses DED1~DED5, the A register is set to '1' as an error flag; and if the converted result is more than 65,535, the carry flip-flop is set to '1' as an error flag.

The simulation is executed in three segments as follows:

1. The test values are set in memory addresses DED1~DED5.
2. The program is executed.
3. The simulator confirms that the contents of addresses BID and BID+1 are the correct value for the conversion of data in addresses DED1 (address 9113)~DED5 (address 9117). At the same time, it confirms that the contents of register A and the carry flip-flop are correct.

The objective program listing is shown in Fig. 2, and explanations of the simulation control commands using this example are shown in Table 4.

Table 2 Memory location and contents

Address	Contents	Explanation of contents
DED1	a	The 5-digit decimal integer is $a \times 10^4 + b \times 10^3 + c \times 10^2 + d \times 10 + e$ and a, b, c, d and e are set in ASCII code.
DED2	b	
DED3	c	
DED4	d	
DED5	e	
BID	Converted results	Low-order 8 bits are stored in BID and high-order 8 bits in BID+1.
BID+1		

Table 3 Error flags for conversion

Number to be converted	Item	Error and no error display		Converted result
		A register	Carry flip-flop	
Integer 0~65,535		0	0	Correct
More than 65,535		0	1	Not correct
Character other than decimal digits		1	0	Not converted

Note 3: Overflow is displayed by being carry flip-flop as 1, and error is so A register as 1.

Fig. 2 Assembly listing of the objective program "CON102"

Table 4 Example of the use of simulation control commands

START M70, CARD	MELCOM 70 is used as the host computer, and the input unit for the control commands is selected to be the card reader.
LOAD START, S	The object program is input from the paper-tape reader (device number 5).
SET CPU SP=10000 PC=9000	The stack pointer is set to the value 10,000, and the program counter is set to the value 9,000.
SET MEMORY, DED1=31# SE M, DED2:DED5=32#, 33#, 35#, 37#	Data is set in memory. 31# is stored in location DED1, 32# in DED2, 33# in DED2+1, 35# in DED2+2, and 37# in DED5.
BREAK C0002, C0003, C0004, C0005	Breakpoints are assigned.
DISPLAY CPU, SP, PC	Displays the contents of the stack pointer (SP) and the program counter (PC) for confirmation.
D M, DED1:DED5	Confirms whether or not the correct value is set in memory. Here, D is the abbreviated command for DISPLAY and M for MEMORY.
GO *	The program is executed until the machine instruction HLT is encountered, printing out the contents of the PC and SP registers and flip-flops at each breakpoint that was assigned by BREAK above.
D M, 9119:9120 (B)	Confirms whether the conversion is correct or not, displaying the result of the conversion in binary form. It can also be confirmed by finding the change of the contents of registers H and L in the list that is printed out during execution.
TIME	The number of cycles executed is counted.
NOBR C0002, C0003, C0004, C0005	The breakpoints assigned with BREAK are released.
S M, DED1=36# S M, DED2:DED5=35# S M, DED4=43#	36# is set in address DED1, 35# in addresses DED2~DED5 and 43# in address DED4.
S CP, PC=9000	9,000 is set in the program counter.
GO	Executes until a HLT instruction is encountered.
D M, 9113:9120	The data and the result are printed in the hexadecimal because the BASF command is not used. In this case, including a character other than 0~9 confirms whether or not a '1' is set in the A register after execution.
SAVE 2, SAV1	Intermediate results are saved in the SAV1 of the disk.

START M70, C	MELCOM 70 is used as the host computer, and the input unit for the control commands is selected to be the card reader.
LO CONT, 2, SAV1	The intermediate results that were saved are loaded from the disk. The file name is 'SAV1'.
TYPE	The input unit for control commands is changed from the card reader to the keyboard.
S CPU, SP=10000, PC=9000	The program counter and the stack pointer are set.
S M, DED1:DED5=37#, 35#	37# is set in address DED1, 35# in DED1+1, 37# in DED1+2, 35# in DED1+3 and 37# in DED5.
GO	Executes until a HLT instruction is encountered. Confirms whether or not a '1' is set in the carry flip-flop because the data exceeded 65,535.
S CPU, PC=9000	The start address is set.
S M, DED1:DED5=30#	30# is set in addresses DED1~DED5.
GO	Executes until an HLT instruction is encountered.
D M, 9113:9120	Confirms the conversion result.
S CPU, PC=9000	The start address is set.
S M, 9113=36# S M, 9115=35#	36# is set in address 9113, 35# in address 9115.
GO	Execution starts. Executes until an HLT instruction is encountered.
D M, 9113:9120	Confirms the conversion result.
END	Declares the end of simulation.

MITSUBISHI MICROCOMPUTERS MELPS 8/85 SOFTWARE

PAPER-TAPE GENERATION PROGRAM FOR PROM WRITERS

DESCRIPTION

This program is used to convert absolute binary object formatted programs, which are produced by the MELPS 8/85 cross-assembler, into other language formats and then produce a paper tape that can be used as input for a PROM writer.

The functional configuration of this program provides for automatic conversion of object programs from one format to another format. In addition, it provides extensions suitable to various applications.

FEATURES

- Producing, selectively, punched paper tapes with simple control commands
- Converting MELPS 8 binary object programs stored on disks into various hexadecimal formats on paper tape
- Converting various hexadecimal formatted paper tapes into MELPS 8 hexadecimal format
- Matching control functions for MELPS 8 hexadecimal formatted paper tape as well as other formats
- Output of various block sizes as specified by the block-size parameter
- Sorting capability to put files in address sequence
- Executing computer is a MELCOM 70 minicomputer
- Implementation language: FORTRAN IV (parts are written in assembler language)

INPUT/OUTPUT MEDIA

- Converts MELPS 8 binary to hexadecimal paper tape.
Input: cartridge disk
Output: paper tape (even-parity ASCII code)
- Converts other hexadecimal paper tapes to MELPS 8

hexadecimal paper tapes.

Input: Paper tape in other hexadecimal format (even-parity ASCII code)

Output: Paper tape in MELPS 8 hexadecimal format (even-parity ASCII code)

- Compares MELPS 8 hexadecimal with other hexadecimal paper-tape formats.

Input: Paper tape (even-parity ASCII code)

Output: Printed on system typewriter.

- Inputs system commands.

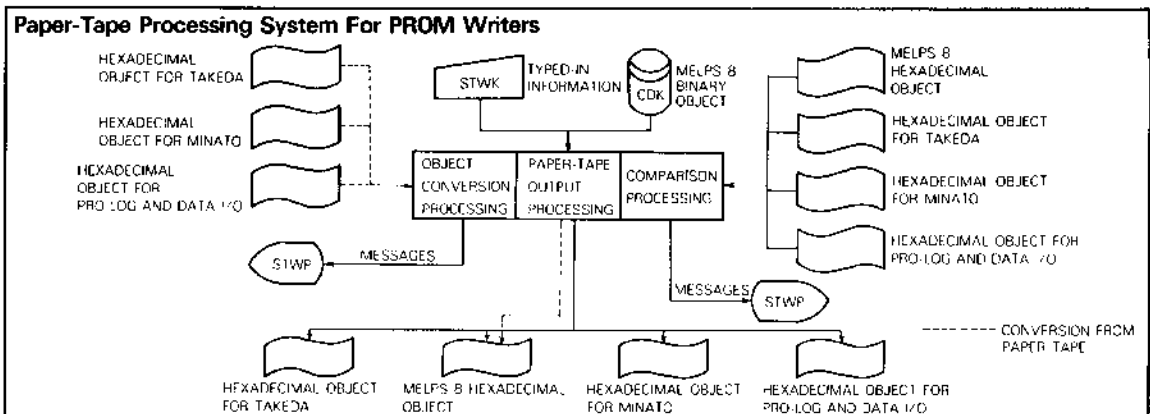

Input using the keyboard of the system typewriter

APPLICATIONS

- Programs are applicable to the M58563S (256-word by 8-bit), M5L 2708K, S (1024-word by 8-bit, M5L 2716K (2048-word by 8-bit) or other similar ROMs when being programmed by a PROM writer made by Data I/O, Pro-log, Takeda or Minato Electronics.

FUNCTION

This program converts absolute binary object programs (abbreviated MELPS 8 binary), created on the disk by the MELPS 8/85 cross assembler, into hexadecimal object programs. These hexadecimal object programs can be used to program PROMs on PROM writers such as those made by Data I/O, the Series 90 made by Pro-log Ltd., the T-310 made by Takeda Riken and the 1830 made by Minato Electronics (abbreviated elsewhere to Data I/O, Pro-log, Takeda and Minato). This program also converts absolute binary object programs into MELPS 8 hexadecimal format and creates a paper tape with blocks of suitable size. The program can also convert paper tapes of Data I/O, Pro-log, Takeda and Minato into MELPS 8 hexadecimal format and compare the functions of each.

MITSUBISHI MICROCOMPUTERS MELPS 8/85 SOFTWARE

SELF ASSEMBLER

DESCRIPTION

The MELPS 8/85 self assembler is a target program that has been prepared for the development of application programs suitable to microcomputers using the MELPS 8/85 CPU and devices utilizing microprocessors.

The PTS-A version of the MELPS 8/85 self assembler requires fewer control commands than the cross assembler, and is capable of assembly, even without a host mini-computer, using an inexpensive debug machine.

The coding for this self assembler is easy, since input data in the MELPS 8/85 self assembler language (B-version) may be handled in free format.

FEATURES

Of the Self Assembler

- May be used on either 3-pass or 2-pass system
- Source input may be in free format
- Source input may be prepared either with paper tape or from the keyboard
- The number of symbols can be increased in accordance with memory capacity expansion
- The execution computer is the MELCS 8/1 and MELCS 85/1 debug machine (with memory more than 8K-bytes and using the BOM-PTS monitor)
- The MELPS 8/85 assembler language (A-version) is used as the implementation language

Of the Self Assembler Language

- 8 pseudo instructions
- Algebraic expressions

- Character constants
- Octal, decimal, and hexadecimal numbers
- The mnemonic codes of the machine instructions are the same as those for the MELPS 8/85 cross assembler and Intel's.

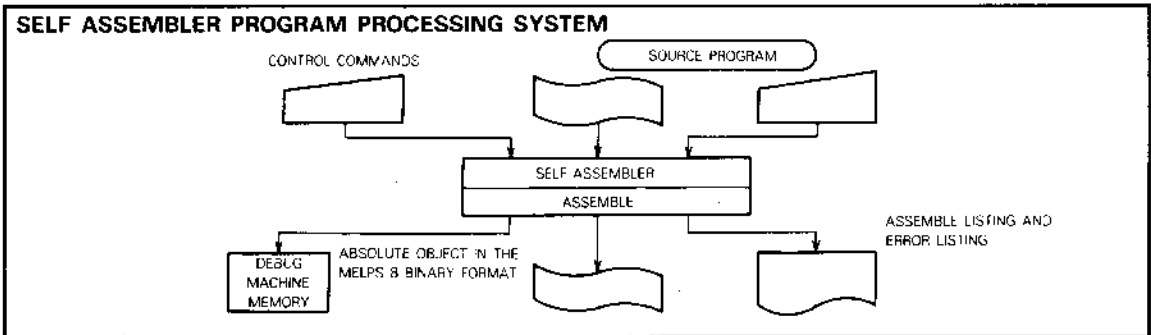

INPUT/OUTPUT MEDIA

- Source input: Keyboard or paper tape
- Control command input: Keyboard
- Object output: Paper tape or debug machine memory
- Program supply media: Paper tape (object)

FUNCTION

This self assembler converts source programs written in the MELPS 8/85 self assembly language (B-version) into absolute objects in the MELPS 8 binary format utilizing the debug machine.

This self assembler can handle 4 control commands for input device assignment, object output device assignment, assembly execution control, and end designation control, and can use both machine and pseudo instructions. The machine instructions, in one-to-one correspondence with machine language, consist of 80 basic instructions (the same as the MELPS 8/85 cross assembler) that are to be subject to object conversion. The pseudo instructions are divided into assembly control, data setting and storage allocation instructions, and consist of eight instructions.

PROGRAM ORDERING INFORMATION

Program name	Ordering number	Program and software manuals included	
MELPS 8/85 self assembler	GA2A S0100	Self Assembly Language Manual (B-version)	GAM-SR00-25A
		Self Assembler Manual (PTS A version)	GAM-SR00-19A
		Self Assembler Operating Manual (PTS-A-version)	GAM-SR00-24A

MANUALS

Manual name	Manual number
MELPS 8 Editor Manual (PTS-A-version)	GAM-SR00-26A
MELPS 8 Editor Operating Manual (PTS A version)	GAM-SR00-27A
MELPS 8 Basic Operating Monitor (BOM-B) Manual	GAM-SR00-23A
MELPS 8 Basic Operating Monitor (BOM-PTS) Manual	GAM-SR00-18A
MELPS 8 Hardware Manual	GAM-HR00-01A

This self assembler facilitates assembly by the use of the control commands shown in Table 1. The assembly consists of the creation of the symbol table in pass 1, where source programs are read from the keyboard or paper tapes, the creation of the assembly list in pass 2, where source programs are read from paper tapes and each instruction is converted into machine language, and the output of absolute objects in pass 3.

SELF ASSEMBLER OBJECT LANGUAGE

The cross assembler is composed of many object modules, and each module is composed of a name part, a symbolic part, a text part and a final part. This self assembler outputs only the text part and the final part in response to the object output control command.

ASSEMBLY LANGUAGE FUNCTIONS

The assembly language that this self assembler accepts consists of the following machine instructions and pseudo instructions.

1. Machine Instructions

There are 80 basic machine instructions. These are con-

verted to their corresponding machine codes and then inserted in the object program. The mnemonic and all the other instructions are the same as for the MELPS 8/85 cross assembler; for these please refer to the Cross Assembler Manual.

2. Pseudo Instructions

The pseudo instructions that this self assembler accepts consist of **ORG**, **NAM**, **PAUS**, and **END** as assembler-control instructions; **EQU**, **DB**, and **DW** as data-setting instructions; and **DS** as storage allocation instruction. These instructions are summarized in Table 2.

3. Language Format

The Self Assembler Language Manual (B-version) is applicable to the language formats for the MELPS 8/85 self assembler; these are equivalent to those for the MELPS 8/85 cross assembler, with some restrictions, and may be handled in a similar manner. In the source program, a statement starts with **CR** (carriage return) and ends with **CR** (carriage return), consisting of label, command, operand, comment, and identification fields.

Table 1 List of control commands for the self assembler

Functional classification	Mnemonic	Function
Input device assignment command	/// SP L { ST SK }	Input device assignment for pass 1 ST Paper tape reader SK Keyboard
Object output device assignment	/// OB L { ST DM }	Object output device assignment ST Paper tape punch DM Debug machine memory
Assembly execution control	/// OP L { L S L C L E } { AN } None None ① ②	Assembly execution start assignment and control of source listing and of object output (1) Listing control LS Source listing needed LC Commentless condensed listing needed LE Listing of error statements only needed None Source listing unnecessary (2) Object output control AN Output of absolute objects without symbol parts None No object output
End designation control command	/// ED .	End of assembly execution designated

Table 2 List of pseudo instructions

Functional classification	Item	Instruction mnemonic, symbol	Name of instruction
Assembly-control instructions		ORG	Program counter setting
		NAM	Program name declaration
		PAUS	Assemble stop
		END	End declaration
Data-setting instructions		EQU	Value symbol setting
		DB	Data setting
		DW	Address setting
Storage allocation instruction		DS	Storage allocation

Table 3 Labels, characters, numerals, and expressions

Sort	Item	Symbol
Label	Label expression	L :
	Initial characters for labels	A ~ Z, @, ?
	Characters, except the initial ones, for labels	A ~ Z, @, ?, 0 ~ 9
	Number of label characters	From one to five (e.g. LABEL1:)
Character constant	A 1 byte	▼A▼
	AB 2 bytes	▼AB▼
	A▼B 3 bytes	▼A▼▼B▼
Numeral	Octal number	n O
	Decimal number	n
	Hexadecimal number	n H
Expression	Add	+
	Subtract	-
	Multiply	*
	Divide	/
Others	Program counter	\$
	Operational order	From left to right

A comment is preceded by a semicolon (;). Since the format is free, any column may be used if the delimiters are properly placed. (Note that the printout for columns 35~72 and 81 and over are neglected.)

Table 3 summarizes the labels, characters, numerals, and expressions, etc.

1. Label field

One~five characters may be used. Only A~Z, @, and ? may be used as the first character and A~Z, @, ?, and 0~9 may be used as the remaining characters. A colon is to be added at the end of the character string.

Label example **L1:MOV A, B**

LABL5:

@ABCD:

A123?:

?AB01:

2. Instruction field

Instruction mnemonic codes are placed in this field. Machine instructions are formed with the same codes as in the MELPS 8/85 cross assembler. The pseudo instructions available are, ORG, NAM, PAUS, and END as assembler-control instructions; EQU, DB, and DW as data-setting instructions; and DS as storage allocation instruction.

3. Operand field

Operands 1 and 2, the first and second operands of the instruction parameters, may be written. When both the operands 1 and 2 are necessary, a comma as a delimiter should be written.

Octal, decimal, and hexadecimal numbers may be used as numerals, formats such as ∇A , ∇AB , $\nabla A \nabla B$, etc. as character constants, expressions combined with operators (+, -, *, /) as expressions, and \$ as the program counter.

4. Comment field

A line preceded by a semicolon (;) and a character string following a semicolon (;) placed at the end of a command or at an arbitrary position along a line are regarded as comments.

Comment examples; **THIS LINE IS COMMENT**
; **COMMENT**

:

L1: MOV A, B; COMMENT; ABC

5. Identification field

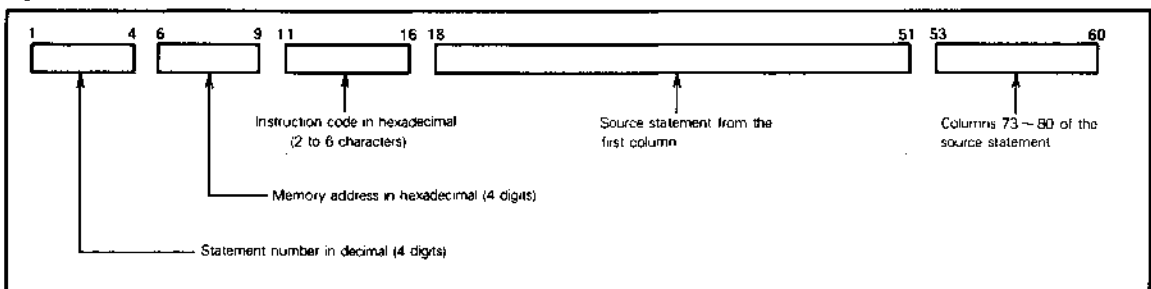

The field is composed of the characters in columns 73~80 or from 1 to 8 characters following !. This field is placed at the end of one statement and may be omitted.

Fig. 1 Source program format

Note: Mark □ denotes space.

Fig. 2 Assemble list format

FORMATS FOR SOURCE PROGRAM AND ASSEMBLE LIST

The coding of source programs is in free format like that shown in Fig. 1.

The format of assemble lists is shown in Fig. 2 and an example of the list is given in Fig. 3.

OBJECT TAPE FORMAT

The object program which is generated in pass 3 is an absolute object program in MELPS 8 binary format.

ASSEMBLE EXAMPLES

Examples of execution of passes 1, 2, and 3 are given in Fig. 4 for paper-tape input and in Fig. 5 for keyboard input.

ERROR MESSAGE FORMAT

Error messages are divided into two types: one for control commands and the other for assemble.

Errors for control commands... * Q *

Errors for assemble... ? □ * x * x: Error code

typed in from a keyboard

DESCRIPTION

The MELPS editor program was developed to make modifications of programs at the source language level easy. This design feature also makes it a useful tool in program development for microcomputers and microprocessors.

FEATURES

- Fifteen easy-to-use control commands
- Convenient loading from the keyboard or by paper tape
- Variable work area to match the application requirements
- Versatile input control
- Easy-to-use buffer-pointer control
- Flexible output control
- Data editing made easy
- String command is possible
- The repetition function of commands shortens input commands
- Editor complete control
- The command format is similar to that used in the MELCOM 70 editor
- Debugging and execution are done on a MELCS 8/1 and

MELCS 85/1 (memory 8K-bytes, monitor BOM-PTS)

- The programming language is MELPS assembler (A version).

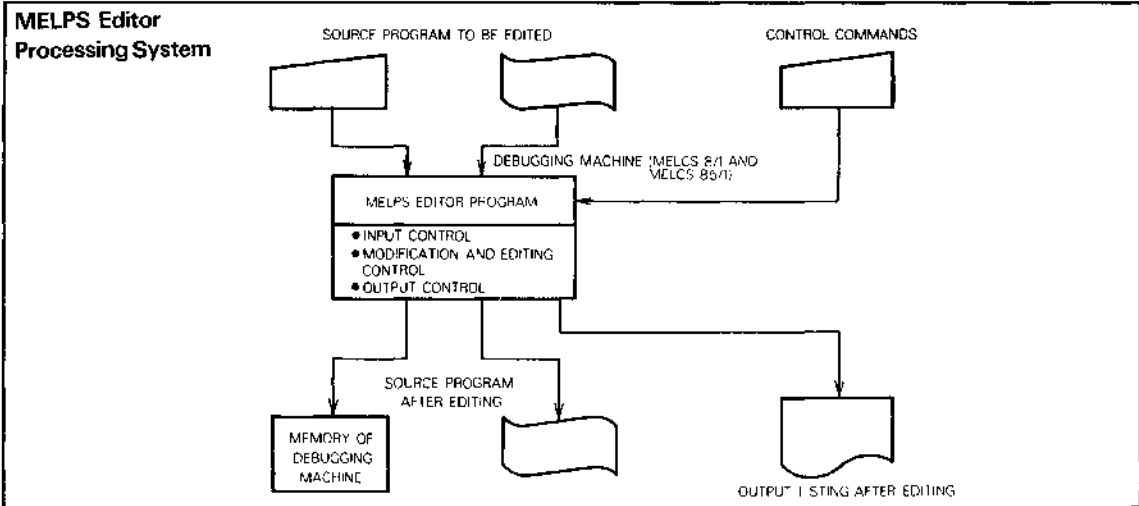

INPUT/OUTPUT MEDIA

- Programs for editing: Keyboard or paper tape
- Control commands input: Keyboard
- Output after editing: Printer or paper tape

FUNCTION

The MELPS editor loads text from paper tape or keyboard into the work area where the text is modified and edited. Control commands for the editor are entered through the keyboard. The edited text is punched out on paper tape, and at the same time the copy can be printed.

The powerful control commands are divided into five functions as shown in Table 1. There are a total of 15 easy-to-use control commands. One instruction can delete, insert or replace from one character to a number of lines. This is facilitated by the flexible control provided for the buffer pointer. The edited results can be punched on paper tape and printed simultaneously.

PROGRAM ORDERING INFORMATION

Program	Ordering number	Program and software manuals included

MELPS 8 Basic Operating Monitor (BOM-PTS) Manual	GAM-SR00-18A
MELPS 8 Hardware Manual	GAM-HR00-01A

FUNCTIONAL OPERATIONS

The MELPS editor is designed to increase the effectiveness of modifying, editing, and debugging programs. There are five groups of control functions: input control, buffer-pointer control, output control, data-editing control and editor end control. There are a total of fifteen control commands listed in Table 1. An explanation of the action of each control command is also given in Table 1. The general format of a control command for input is shown in Fig. 1.

1. String commands

The control commands can be used independently or they can be combined into a string as shown in the example that follows.

```
///BP$5TW$2CP$3DL$RPA$B$$
```

2. Command repetition

The format for repetition of a command is as follows:

```
n <command string <command string <... <... >>>
```

Where n is a decimal number and $|n| \leq 255$, if n is negative, it is converted to a positive number. The command string between <and> will be repeated n times. Repetition command nesting of <and> is limited to eight levels.

An example of command formats and how they can be stringed follows. The contents of the work area before and after execution are also shown in Fig. 2.

Fig. 1 General format of input commands

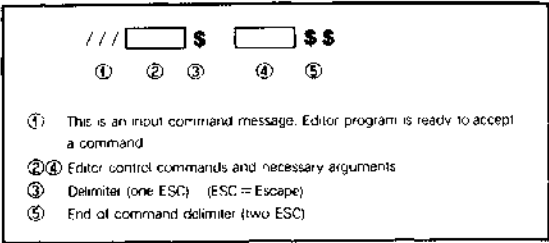

Fig. 2 Typical editor command

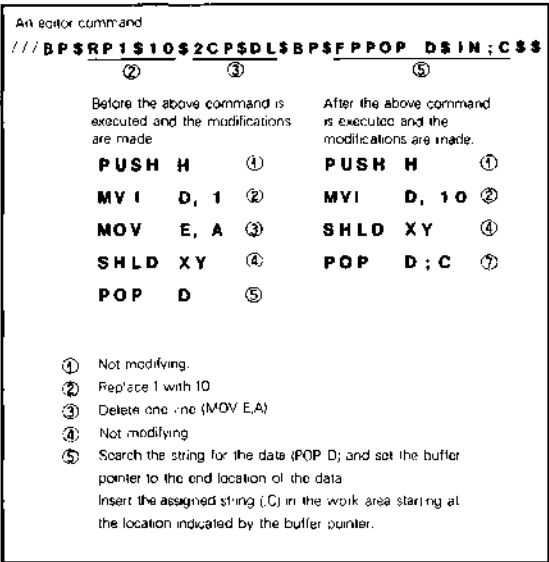

Table 1 Editor control commands and an explanation of their actions

Control function	Control command	Mnemonic	Action
Input control	Source load	LD	Assign the input device for text load and load text
Buffer-pointer control	Buffer-pointer initial setting	BP	Set the buffer pointer to the first address of the work area
	Buffer-pointer character setting	CP	Move the buffer pointer n characters.
	Buffer-pointer line setting	LP	Move the buffer pointer n lines
	Buffer-pointer end setting	EP	Move the buffer pointer to the end of the work area.
Output control	Print typewriter	TW	Print n lines.
	Line punch	PN	Punch n lines from the first line of the work area
	Punch work area	PP	Punch all the contents of the work area
	Punch sprocket holes	PS	Punch sprocket holes for n bytes.
Data-editing control	Delete character	DC	Delete n characters
	Find and buffer pointer setting	FP	Search the string for the data and set the buffer pointer to the end location of the data.
	Replace	RP	Locate data to be replaced and replace with the new data
	Delete line	DL	Delete n lines
Editor end control	Insert	IN	Insert the assigned string in the work area starting at the location indicated by the buffer pointer.
	End	EN	End of editor processing.

BASIC OPERATING MONITOR—PAPER-TAPE SYSTEM

DESCRIPTION

The BOM-PTS basic operating monitor was developed for microcomputers that use the M5L8080A 8-bit parallel CPU. It controls execution and debugging of the user's program. The BOM-PTS has a program capacity of 7.5K-bytes and drives the system typewriter (Casio Typuter, Model 500 or 501) as its I/O unit.

FEATURES

- Has 3 macro instructions and 22 monitor commands
- Provides trace, snapshot, and address halt commands for effective program development and debugging
- Has pseudo I/O and PROM write functions

FUNCTION

The BOM-PTS 22 monitor commands and 3 macro instructions provide the following functions:

1. Program execution control
2. Program loading
3. Memory punching
4. Program debugging (trace, snapshot, and halt commands)
5. I/O control and pseudo I/O processing
6. Memory and register data display, and data alteration
7. PROM writing function

Starting BOM-PTS Execution

When the BOM start switch on the panel of the debugging machine MELCS 8/1 is turned on, the following message is printed out. After the printout, monitor commands can be entered.

```
BOM-PTS A00 'READY'
//
```

Hardware Limitations

1. Memory Configuration

Memory locations in the ROM are:

E000₁₆~FCFF₁₆

In addition to the ROM, the following 78 bytes of RAM area are required:

F000₁₆~EDFF₁₆

2. Input/Output Device Addresses

PTR, for keyboard input: 7B₁₆ (IN 7B#)

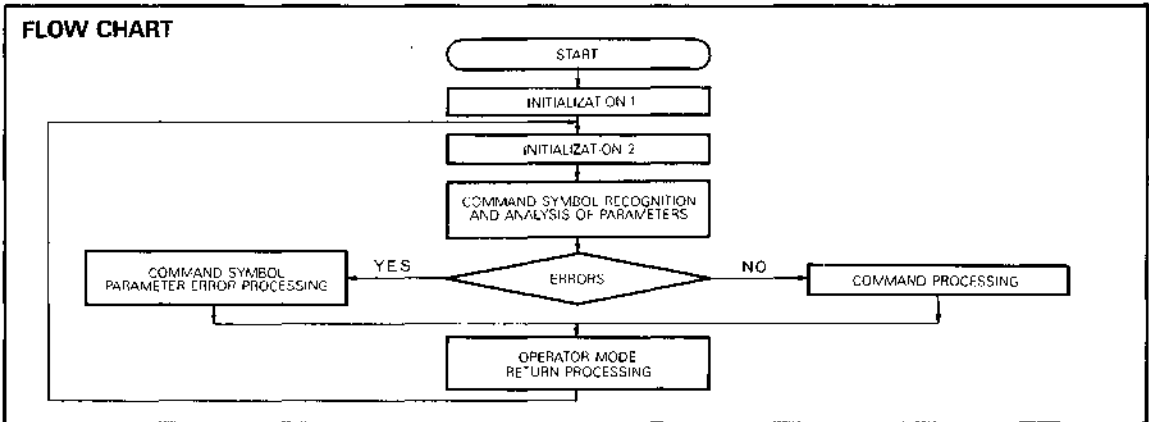

PTP, for printout: 7B₁₆ (OUT 7B#)

Status input: 7B₁₆ (IN 7B#)

The structure of the status bits is as follows:

DADR DL Setup of the I/O data-storing memory length

MITSUBISHI MICROCOMPUTERS MELPS 8 BOM-B

BASIC OPERATING MONITOR—BASIC SYSTEM

DESCRIPTION

The MELPS 8 BOM-B basic operating monitor was developed for microcomputers that use the M5L8080A 8-bit parallel CPU. It controls execution and debugging of the user's program. It is contained in 2K-bytes of memory and drives the system typewriter (Casio Typuter Model 500) as its I/O unit.

FEATURES

- Available as a standard mask ROM (M58731-001S). It can also be programmed into a ROM for a micro-computer configuration that incorporates program debugging functions.
- Has 3 macro instructions and 9 monitor commands
- Allows addition of user's monitor commands
- Cannot be destroyed by a user's program

FUNCTION

The 9 monitor commands and 3 macro instructions provide the following functions:

1. Program execution control
2. Program loading
3. Memory punching
4. Program debugging
5. I/O control

Starting BOM-B Program Execution

When program execution is started at address 6800_{16} , the following message is printed out.

```
//MELPS 8 BOM-B A01
//
```

After the printout, monitor commands can be entered.

Hardware Limitations

1. Memory Configuration

Memory locations in the ROM are:

$6800_{16} \sim 6FFF_{16}$

In addition to the ROM, the following 78 bytes of RAM area are required:

$3F80_{16} \sim 3FCD_{16}$

2. Input/Output Device Addresses

PTR, for keyboard input: $7B_{16}$ (IN $7B_{16}$)

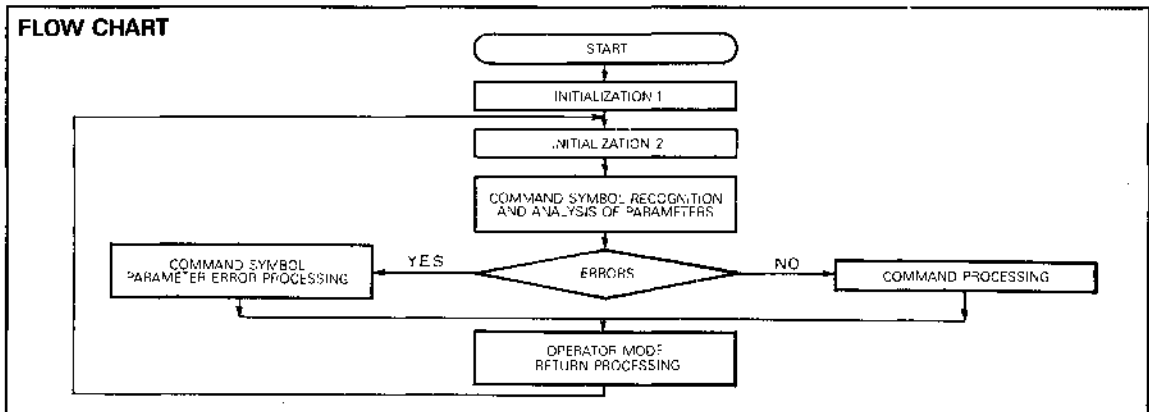

PTP, for printout: $7B_{16}$ (OUT $7B_{16}$)

Status input: $7B_{16}$ (IN $7B_{16}$)

The structure of the status bits is as follows:

FLOW CHART

BASIC OPERATING MONITOR—BASIC SYSTEM

Monitor commands and macro instructions for BOM-B.

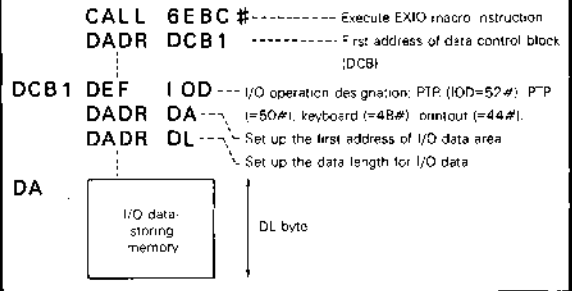

Name	Function	Command designation and parameter input format or calling sequence	Parameter
	G	Change start address	/// G para 1 (4): Start address
	R	Restart of program	/// R CR LF para 2 (4): Change start address
	L	MELPS 8 binary loader	/// L CR LF
	H	MELPS 8 hexadecimal loader	/// H CR LF
Commands	T	Punch MELPS 8 binary test block of the memory data	/// T para 1 (4), para 2 (4) CR LF para 1 (4): First address para 2 (4): End address
	E	Punch MELPS 8 binary end block	/// E [para 1 (4)] CR LF para 1 (4): Start address
	P	Print hexadecimal test block of the memory data	/// P para 1 (4), para 2 (4) CR LF para 1 (4): First address para 2 (4): End address
	S	Substitute memory	/// S para 1 (4) CR LF para 1 (4): Change address
	M	Print and modify register data in hexadecimal format	/// M CR LF
Macro instruction	EXIT	End of program	CALL 6806 #
	PAUSE	Pause program execution	CALL 6803 #
	EXIO	Input/output control	

Note 1 : para n (m). This designation shows the nth parameter in a command (operator input or monitor printout), and also shows it to be a hexadecimal parameter (0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F) of which the significant digits are 1~m. If the length exceeds m, the least significant digits are valid.

2 : (underline): Indicates input by an operator.

3 : [] (bracketing): Indicates input by an operator that can be omitted.

4 : #. Indicates a hexadecimal number in assembler language.

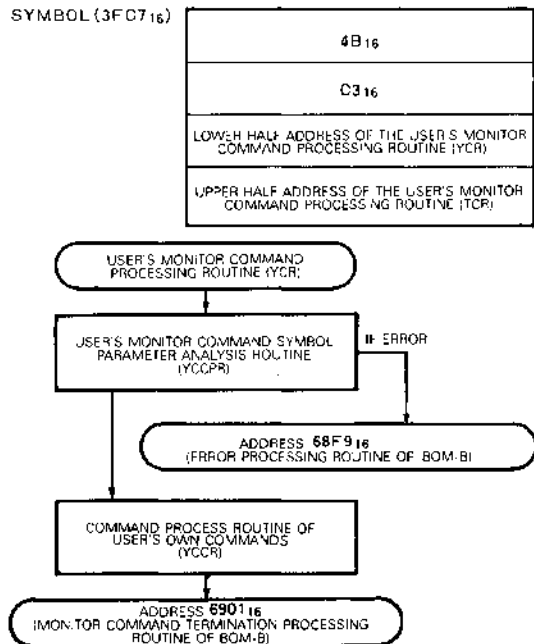

HOW TO IMPLEMENT USER'S OWN MONITOR COMMANDS

It is feasible to implement new monitor commands, which are prepared by a user for his own need, by correcting four bytes (3FC7₁₆~3FCA₁₆) of the record in the RAM. The user's monitor commands are then added as follows:

1. Set the data in "4B₁₆" to SYMBOL.
2. Set the data in "C3₁₆" to SYMBOL + 1.
3. Set the starting address of the user's monitor command processing routine (YCR) low-order into SYMBOL + 2 and high-order into SYMBOL + 3.
4. Then a symbol parameter analysis routine and command processing routine are prepared as required for the user's command.
5. Command symbols used for the user's monitor commands should not be identical with any of the 9 command symbols used in BOM-B.
6. Both command symbol and parameter errors are checked in the YCR, and a jump is executed to address 68F9₁₆, where the error processing routine of the BOM-B is residing, when an error is found. A question mark (?) will be printed out in case an error is found.
7. The last step of the YCR must be a jumped to address 6901₁₆, where the monitor command termination processing routine is stored.

PROCESS FLOW OF USER'S MONITOR COMMANDS

APPLICATIONS

MEMORY DEVELOPMENT APPROACHES

1. LARGE-SCALE SEMICONDUCTOR MEMORY DEVELOPMENT APPROACHES

Introduction

The IC age which began in 1965 progressed into the 1970's to see the beginning of a full-swing push towards LSI and in 1978 to the advent of VLSI, the 64K-bit RAM. Going into the 1980's, the 64K-bit RAM is being used practically in systems, and in February 1980 two announcements of 256K-bit RAM development in Japan were made at the International Solid State Circuit Conference (ISSCC) held at San Francisco. The VLSI Joint Research Laboratory has pointed out the possibility of megabit memories, a development which may materialize in the form of a 1M-bit RAM by the mid 80's.

The ever-increasing level of integration in MOS memory devices has been supported by three areas of advancements,

- Circuit engineering advancements
- Process accuracy and micro-process advancements
- Increase in chip size

Using the ISSCC report material as a basis we will examine some practical approaches to the development of megabit memory devices and some of the problems involved in this effort.

Approaches to Megabit Memory Development

Table 1.1 summarizes some typical approaches that have been proposed for the development of megabit memory. As is clear from this outline, areas for potential study include improvements in cell structure and development of methods to overcome the presence of failed bits in large-scale memories as well as the obvious aim of development of smaller and smaller memory cells.

Table 1.1 Approaches to Megabit Memory Development

Approach		Prototype results		Description	Announced by	Year Month
		Capacity (bits)	Chip size			
Device	Micro-process	256k	4.8 × 8.6mm	Single 5V operation 1 transistor and 1 CMOS to form the cells, L = 1.5μm	NTIS	80 2
		256k	5.8 × 5.8mm	Same as above, L _{eff} = 1.2μm, molybdenum gate with spire cell.	NTT	80 2
	New structure	0.5 M	(10 × 10mm)	Same as above, QSA (quadruply self-aligned), L = 2μm	Joint Research Laboratory	80 2
		64k	24mm ²	Same as above, 3-layer polysilicon	NS	79 2
		64k	25.2mm ²	Same as above, VMOS, L ≥ 4μm	Siemens	79 2
		64k	30mm ²	MOS 1 transistor, 1 capacitor bipolar configuration, 8K-word × 8 bits	IBM	80 2
Logic/circuitry	Failed bit saving	4M		Masked PRDM using the full wafer	NTT	80 2
		64k	4.3 × 9.4mm	With spare decoder Partial (Half-good)	Bell Labs Teradyne	79 2 80 1
	Redundancy	1M		RAM using full wafer, 2 × 32K-word × 20 bits with 2 spare bits	NTT	79 2
		64k		3-layer connections, Al gate, 8-bit register built-in	IBM	80 2

Memory Cell Structure Overview

The remarkable progress that has been made in the development of highly integrated MOS memories has centered around the development of static devices using structural elements of six, four, three, and finally two elements and ultimately the transition to dynamic devices with improvements in the surrounding circuitry and the development of micro-patterns as well as the use of larger and larger chips. From the standpoint of the number of cells used in large-scale memories, since the development of two-element cells using one MOS transistor and one MOS capacitor, devices have progressed from the originally developed 4K dynamic RAM through 16K, 64K, and today 256K RAM devices. Several proposals have been made for a 1-element memory cell, placing the megabit memory within the realm of possibility. We will discuss here several examples of 1-element and 2-element cells and the approach to fabrication of megabit memories.

1. Polysilicon Bit Line Cells

To increase the read voltage for 2-element cells, the ratio of

the MOS capacitance to the bit line floating capacitance must be made as high as possible in a small area. Another reason for making the MOS capacitance as high as possible is the reduction of soft errors caused by minute amounts of a particles included inside the package material. For this reason, polysilicon has been replacing n⁺ defused material for the fabrication of bit lines. Fig. 1.1 illustrates the example of a Mostek 64K RAM. By making the second polysilicon layer (POLY II) the bit line, the activated region area is most effectively used and the MOS capacitor value is increased while the bit line floating capacitance is decreased. Fabricating the bit line from polysilicon is an effective means of reducing soft error rates as well (in the depletion layer between n⁺ bit line region and p substrate, electrons generated by a particles collect in the bit lines and generate noise but this is of a decreased level). The process for this type of cell is characterized by a reduced resistivity for the polysilicon layer and the fabrication of a buried contact between the polysilicon bit line and the n⁺ fused layer.

MEMORY DEVELOPMENT APPROACHES

Fig. 1.1 Diffused bit line (a), and polysilicon bit line (b)

2. Hi-C RAM Cell

For 2-element cells the junction capacitance associated with and parallel to the MOS capacitor can be used effectively to form a Hi-C RAM cell. Fig. 1.2 (a) illustrates a conventional cell in which the sum of the MOS capacitance C_{OX} formed by the inverted layer and storage gate and the junction capacitance C_D formed by the inverted layer and the p substrate is used as the capacitance for data storage. In conventional dynamic RAMs, the p-type impurity density is $1\sim 2 \times 10^{15}/\text{cm}^2$ so that C_D is $\ll C_{OX}$ and so C_D is ignored. In the Hi-C cell illustrated in Fig. 1.2 (b), a $n^+ - p^+ - p$ junction is formed just below the storage gate so that the spreading of the depletion layer between the n^+ region and p substrate is reduced, increasing the value of C_D . A simple approximation expression for C_D is given below.

$$C_D = \sqrt{\frac{\epsilon_{Si} \cdot q \cdot N_A}{2(V_S + |V_{BB}|)}}$$

In this expression, ϵ_{Si} is the dielectric constant for silicon, q is the charge of an electron, N_A is the impurity density of the p-type semiconductor, V_S is the potential of the n^+ region, and V_{BB} is the potential of the p-type substrate. For the Hi-C cell, the value of N_A is made large. For a storage gate oxide layer 50nm, the ion implant of impurities required for the formation of a p^+ region is $1 \times 10^{13}/\text{cm}^2$ making the expected value of $(C_{OC} = C_D)/C_{OX}$ 1.63 (actual measurements have shown this to be 1.67). In this manner, using the same area, the data storage capacitance is increased more than 60% allowing the bias potential to be made equal to the ground potential. In previously used cell structures, to form the inverted layer it was necessary to provide a bias voltage, V_{DD} . For this

reason, variations in the value of V_{DD} created the danger of read errors. With the Hi-C cell structure this danger is completely eliminated. One process difficulty arises however in that the Hi-C region may not self-align with the storage gate and transfer gate.

Fig. 1.2 Conventional cell (a), and Hi-C RAM cell (b) cross-sections

3. 3-Layer Polysilicon Cell

While the Hi-C cell is improved by correction of the internal vertical structure of the substrate, the 3-layer polysilicon cell and stacked capacitor RAM cell (STC RAM) represent the approach of correction of the vertical structure of the surface of the substrate. Fig. 1.3 illustrates the cross-section of a National Semiconductor 3-layer polysilicon cell. The capacitance formed by Poly 1 and Poly 2 is used for data storage, while Poly 1 is connected through a buried contact to the source of the self-aligned transfer gate formed by Poly 3. Poly 2 is biased to ground potential. The 3-layer polycell features a data storage capacitance formed by a polysilicon structure and an $n^+ - p$ junction capacitance C_D formed by a very small surface area (in the example shown in Fig. 1.3, the $n^+ - p$ junction takes up only 1/15 of the total storage node surface area). For this reason, the leakage current is small, enabling good data hold properties, while reducing α particle related soft error rates. The process is characterized by the necessity to fabricate a third polysilicon layer, reduce the resistance of the polysilicon material, and fabricate the buried contact.

MEMORY DEVELOPMENT APPROACHES

Fig. 1.3 3-Layer polysilicon cell example

4. VMOS RAM Cell

Semiconductor technology has focused on the use of silicon in a planar structure. VMOS technology has been developed however to increase the level of integration by means of forming vertical channels. VMOS uses anisotropic etching to form V-shaped grooves in the silicon surface, forming a channel along the wall of the grooves. Fig. 1.4 illustrates the cross section structure of a dynamic RAM cell introduced recently by AMI. In the VMOS cell, the junction capacitance formed by the buried n^+ region and the p^+ substrate is used for data storage. A p^+ layer is epitaxially grown on the p region of the p^+ substrate surface by means of autodoping of impurity atoms. The p region along the surface of the V-shaped groove forms the n^+ drain (bit line), n^+ source (junction data storage capacitance), metal gate (word line) which form the VMOS transistor and determines its effective channel length. As is clear from the figure, the data storage capacitance is included in the area of the VMOS transistor (transfer gate), so that the level of integration is double that of a planar-type 2-element cell device. Siemens has produced a prototype of a VMOS 64K RAM ($4\mu\text{m}$ grid device), the cell area being $215\mu\text{m}^2$ and the chip area being 25.2mm^2 . VMOS technology was first used to produce static circuits as well as dynamic memory and EPROM. However, the gates formed are susceptible to voltage breakdown and formation of the V-shaped groove caused process difficulties.

Fig. 1.4 VMOS dynamic RAM cell cross-section

5. Stacked Capacitor RAM Cell

To form 2-element cells, the data storage capacitance can be implemented as a MOS capacitor, MIS capacitor (using for example silicon nitride, Si_3N_4 , as a dielectric), or the junction capacitance. Fig. 1.5 shows the example of an MIS capacitor being used. The capacitor is formed by a layer of tantalum (Ta) and a layer of molybdenum (Mo) between which is a layer of tantalum oxide (Ta_2O_5). The dielectric coefficient of Ta_2O_5 being 22, much higher than that of silicon at 3.9, enables a very small cell area to be used to store a large electric charge. The transfer gate is formed by the shallow junction between the gate polysilicon and source drain and the deep n^+ region and contact hole which form a quadruply self-aligned (QSA)-MOST, enabling an improvement in level of integration. For devices designed on a $2\mu\text{m}$ grid, the space required for a 512K-bit and 1M-bit RAM is 4.8×9.5 and $9.2 \times 9.5\text{mm}$ respectively, placing megabit memory devices in the realm of possibility at last. The device process involves heretofore undeveloped technologies such as those required to process Ta, Ta_2O_5 and Mo, placing some stumbling blocks in the way of development of this new technology. As with other techniques, however, the common problem of lowering the resistivity of polysilicon exists.

Fig. 1.5 Stacked capacitor top view (a), and cross-section (b)

MEMORY DEVELOPMENT APPROACHES

6. CCRAM (Charge Coupled RAM) Cell

With the exception of the VMOS cell which makes use of the junction capacitance only for data storage, 2-element cells require three lines; storage gate, bit, and word lines. The allowance of space for these three lines results in a lowering of space usage efficiency. To overcome this disadvantage, the CCRAM cell uses one gate for both the storage gate and transfer gate functions. Fig. 1.6 (a) shows an example of the cross-section structure of a CCRAM cell, illustrating the shallow n^+ and relatively deep p^+ regions directly under the storage gate resembling a Hi-C region in the silicon substrate surface. The n^+ region is designed to shift the flat band voltage V_{FB} so as to separate the transfer gate and n^+ bit lines by the stored data (or potential void) with the transfer gate (word line) off and data stored. When the transfer gate is turned on (for read or write), the potential directly below the gate becomes more positive than the potential on the surface directly below the storage gate (due to the p^+ region of the storage gate), so that electrons freely flow in the bit line (Fig. 1.6 (b)). This operation is exactly the same as previously developed 2-element cells. Process problems, similar to those of the Hi-C cell, include the self-alignment of the n^+ - p^+ regions, the setting of the flat band voltage, and operating margin sensitivity to process parameter variations.

Fig. 1.6 CCRAM cell cross-section (a), and surface potential (b)

7. MCM (Merged Charge Memory) Cell

Whereas the CCRAM cell makes use of a combined storage gate and transfer gate, the MCM cell is one in which the bit line and storage gates are combined. In the structure shown in Fig. 1.7, the charge representing data is stored in the form of minority carriers in the potential void directly below the intersection of the word line and BSS (bit storage/sense) line. Depending upon whether the write data is zero or one, the DSS line potential V_{BH} will be set to a high value (forming a deep potential void) or a middle value of $V_{BH}/2$ (forming a shallow potential void). By setting the word line potential to approximately $V_{BH}/2$, the charge from the n^+ diffused line is stored as a zero or a one in the potential void. The holding of zero and one data from thereon with BSS line potential as V_{BH} is done with the potential void filled either half way or virtually empty. For reading, the BSS line is floated, and the n^+ diffused line is set to ground potential. The word line is then set from a negative potential (the potential for data hold) to a value of $V_{BH}/2$. The charge flowing out of the n^+ diffused line fills its potential void, while reading is done by means of a source follower circuit used to output as one or zero the voltage drop caused by the BSS line capacitor junction corresponding to the originally empty void. For this structural reason, the MCM cell has no contact hole and does not necessitate the alignment of pn junctions, such that if W is the minimum line width, the surface area for one cell becomes approximately $4W^2$ as the theoretically smallest value. Difficulties arise however from the fact that the charge per unit area is low, the ratio of BSS line to storage capacitance is large, and the pitch is narrow, creating problems in the implementation of sense amplifier and decoding circuits (at present, sense circuits fitting within a $2W$ pitch have not been devised).

Fig. 1.7 MCM cell conceptual diagram

MEMORY DEVELOPMENT APPROACHES

8. Taper Isolated RAM Cell

The cell previously described are combinational forms using basically two elements to store one piece of data and requiring one transfer gate. Texas Instruments have developed the taper isolated dynamic gain (TIDG) RAM in which the threshold levels for one and zero of a single MOS transistor have been changed, eliminating the requirements for a capacitor for writing and hold. Operation is similar to dynamic RAM, with reading done by detection of differences in current drive capabilities of the transistor caused by threshold value differences in comparison with fixed charge reading used with previously developed cells. Fig. 1.8 shows the equivalent circuit for a TIDG cell as well as the cross-section cut in the channel width direction and the surface potential. The p and n implanted levels and diffusion depth are chosen such that a potential higher than that directly below the gate oxide layer is formed in the taper between the thick oxide layer and the thin gate oxide layer, so that a potential barrier is formed as shown in Fig. 1.8. The result of this is that, directly below the gate, sufficient holes accumulate to form a channel (low threshold level) or that the majority of holes are driven out such that a channel does not form (high threshold level), data storage being determined as one or zero depending on which situation exists. Data writing (zero) is performed by driving holes out of the substrate and channel stop regions by applying a high potential to the gate and low potential to the source and drain. Because this type of cell requires only one polysilicon layer, it is thought to have great applications in the implementation of megabit scale memories. Variations in characteristics, however, are seen to be difficult to control.

Fig. 1.8 Equivalent circuit (a) and cross-section (b) of the Texas Instruments TIDG cell

9. Mostek ROM Cell

While it is not a dynamic RAM cell, the 64K ROM cell of the Mostek Company is of some interest. Fig. 1.9 shows the top view of the device. The transistor threshold is programmed as either high or low level. The column line is high-level for the standby state, and changes to a virtual ground for the decoded condition, outputting the precharge bit line potential as is or at a lower level as data. This cell and the associated circuit configuration was announced at the ISSCC simultaneously as an EPROM application by Motorola, Mostek, and Texas Instruments. For the EPROM application, a floating gate is fabricated at the upper part of the transistor shown in Fig. 1.9. This cell structure and surrounding circuit configuration is usable in such applications as the previously described taper isolated cell and is expected to yield advancements in that area.

Fig. 1.9 Mostek 64K ROM cell

MEMORY DEVELOPMENT APPROACHES

Saving Failed Bits

As a separate but related field to memory cell structure, the saving of failed memory bits is being studied and several methods have been attempted. One method, developed by device users, results in the effective usage of a device within which several failed bits or even one half of the entire device has been detected to be bad. The other relies on the provision of spare bits to form a redundant backup system for failed bits. Here we will discuss several examples of the latter method.

1. Bell Laboratories — Fault Tolerant 64K RAM

This method relies on the external creation of shorts and open circuits between spare bits and failed bits. The Bell Laboratories example consists of the use of a laser to open circuits by cutting the polysilicon material. The addresses of failed bits detected during a wafer test are recorded. A decoding circuit is then used to process addresses. Fig. 1.10 shows a possible laser program decoding circuit. The laser is used to cut the polysilicon links which are imbedded below the passivation layer. The decoding circuit is used to select the spare bit lines. The laser is programmed such that the stage subsequent to the selected line output is clamped to a low level. Since this method relies on laser cutting, it presents some practical difficulties. The Mostek method to be discussed next eliminates these difficulties by electrically saving the failed bits and is expected to be a useful technique for the future.

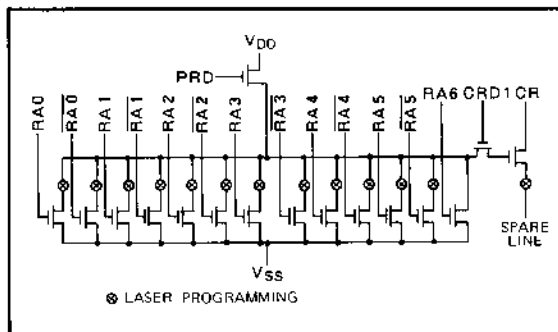

Fig. 1.10 Bell Laboratories failed bit saving decoder circuit

2. Mostek Example — 5V 64K EPROM

Mostek applies failed bit saving techniques to EPROM devices. To improve yield, 8K of spare cells, spare column decoder, spare column selector, spare sense amplifier, and spare data input buffer are provided in addition to the 64K-bits of memory cells. When a failed bit is detected during a wafer test, the \overline{CE} input is driven at 25V, the result of which is that (see Fig. 1.11) \overline{RPR} becomes 25V and $\overline{R\overline{P}R}$ goes from 5V to 0V. Transistor Q_1 turns on, and the polysilicon resistance R is cut by the voltage $V_{PP} = 25V$. In this way, the repair buffer selects the spare matrix. The advantage of this method is, of course, that the entire process is handled electrically.

Another example of electrical saving of failed bits was disclosed by Japan Telephone and Telegraph. In this example a failed bit is detected during the wafer test and the connection to the spare decoder corresponding to this address is made by forming a short circuit by destroying a polysilicon p-n junction. These examples are methods that can be used to increase yield of complete 64K and 256K devices. Another technique which might be used is that which provides the device with an onboard correction circuit which can save the device from even soft errors. Whichever technique is adopted, it is clear that technological breakthroughs are going to be necessary if progress in large-scale memory development is to continue.

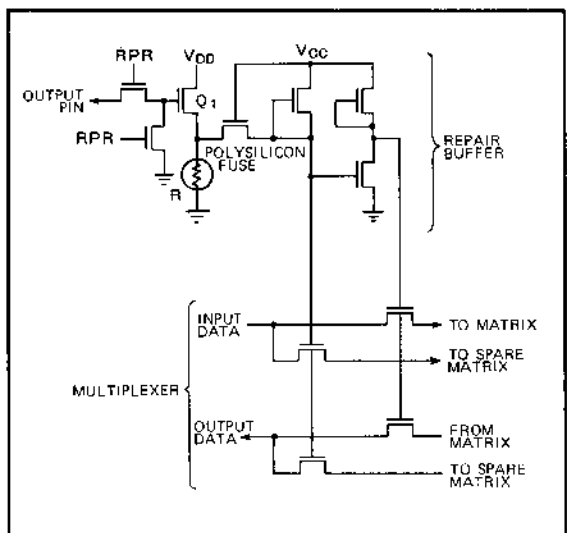

Fig. 1.11 Mostek EPROM failed bit saving method

Summary

As can be seen, various approaches are being attempted to the development of megabit memory devices, including study in the area of effective usage of such devices, device structure, and recovery from soft errors, all of which is progressing in spite of inherent process limitations. By the year 2000 it is expected that 4M-bit devices with access times of $1\mu s$ will be producible in an area of $4cm^2$. To provide this new technology required by our modern society, the semiconductor industry will have to mobilize its circuit device and process technologies in a concerted effort.

MITSUBISHI LSIs 16K-BIT DYNAMIC RAM

(M5K4116P, S)

2. 16K-BIT DYNAMIC RAM

2.1 M5K4116P,S TECHNOLOGY

INTRODUCTION

The M5K4116P, S are 16 384-word by 1-bit dynamic RAMs, fabricated using the n-channel silicon-gate MOS process, and ideal for large-capacity memory systems where high speed, low power dissipation, and low costs are essential. The use of double-layer polysilicon process technology and single-transistor dynamic storage cells provide high circuit density at reduced costs, and the use of dynamic circuitry including sense amplifiers assures low power dissipation. Multiplexed address input permits both a reduction in pins to the standard 16-pin package configuration and an increase in system densities.

Table 2 compares the M5K4116P, S 16 384-bit dynamic RAM with a 4096-bit static RAM.

Table 2.1 Comparison of the 16,384 bit dynamic RAM and 4K static RAM

Device Characteristics	16K dynamic RAM	(Note 1) 4K static RAM
Total power	462mW max	440mW max
Power/bit	28.2 μ W	107.4 μ W
Speed	$t_a = 150$ ns	$t_a = 200$ ns
Power \times speed/bit	4.23pJ	21.5pJ

Note 1. M5L2114P-2

As can be seen, the power \times speed per bit of the 16K dynamic RAM is 4.23pJ, only 1/5 that of the 4K static RAM.

Fig. 2.2 Block diagram

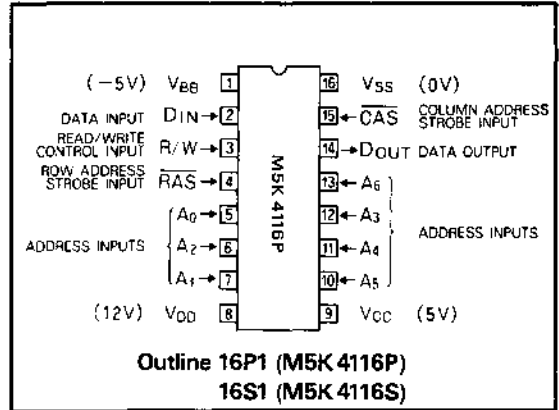

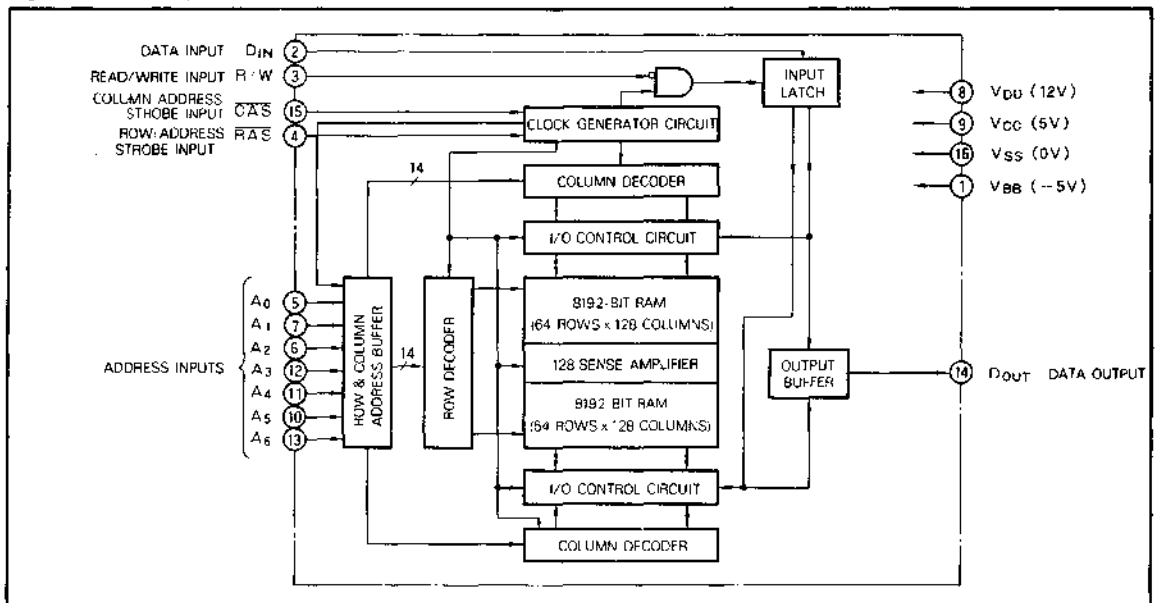

Fig. 2.1 Pin configuration (top view)

Table 2.2 compares the requirements of the two RAM types when a 16K-byte memory system is constructed.

Table 2.2 Requirements for a 16K-byte memory system

Device	Number of RAMS	Voltage	Current	Over-all power	Relative power	Relative size
4K-bit static RAM	32	5V	@ 2.56A	12.8W	1	1
16K-bit dynamic RAM	8	5V 12V -5V	* @ 0.28A @ 2mA	3.37W	0.26	0.25

* Current from VCC is neglected because VCC is only connected to output buffer.

MITSUBISHI LSIs
16K-BIT DYNAMIC RAM

(M5K4116P, S)

FUNCTION

In addition to normal read, write, and read-modify-write operations, the M5K4116P, S provide a number of other functions, e.g., page-mode, $\overline{\text{RAS}}$ -only refresh, and delayed-write. The input conditions for each are shown in Table 2.3

If you interchange address pins as shown in Fig. 2.3, you can get a sequential location map for the 16,384 memory bits.

Table 2.3 Input conditions for each mode

Operation	Input						Output	Re-fresh	Remarks

**N-CHANNEL DOUBLE-LAYER POLY SILICON GATE
MOS PROCESS**

In order to fabricate the M5K4116P, S series, single transistor memory cells and the N-channel double-layer poly-silicon gate MOS process are used. There is no diffusion area between switching transistor Q and the data-storage

memory capacitor because of the use of the double poly-silicon gate MOS process, so that the memory cell area is reduced by 75% from that of the previous process.

SUMMARY OF OPERATIONS

Addressing

To select one of the 16 384 memory cells in the M5K 4116P, S, the 14-bit address signal must be multiplexed into 7 address signals, which are then latched into the on-chip latch by two externally applied clock pulses. First, the negative-going edge of the row-address-strobe pulse ($\overline{\text{RAS}}$) latches the 7 row address bits; next, the negative-going edge of the column-address-strobe pulse ($\overline{\text{CAS}}$) latches the 7 column-address bits. Timing of the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ clocks can be selected by either of the following two methods.

Fig. 2.7 Address multiplex

1. The delay time from $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$ $t_{d(\text{RAS-CAS})}$ is set between the minimum and maximum values of the limits. In this case, the internal $\overline{\text{CAS}}$ control signals are inhibited until almost $t_{d(\text{RAS-CAS})\text{max}}$ ('gated $\overline{\text{CAS}}$ ' operation). The external $\overline{\text{CAS}}$ signal can be applied with a margin not affecting the on-chip circuit operations (e.g. access time), and the address inputs can easily be changed from row address to column address. This interval is called the 'multiplex time'. Eq. 1 gives the multiplex time.

$$t_{\text{MUX}} = t_{d(\text{RAS-CAS})} - t_T - t_h(\text{RAS-RA}) - t_{\text{SU}}(\text{CA-CAS}) \quad \dots \text{Eq. 1}$$

In the next conditions, the multiplex time (t_{MUX}) is maximized.

$$\begin{aligned} t_{d(\text{RAS-CAS})} &= \text{max} \\ t_h(\text{RAS-RA}) &= \text{min} \\ t_{\text{SU}}(\text{CA-CAS}) &= \text{min} \end{aligned}$$

Table 4 shows the maximum multiplex time in the case where the access time is not greater than $t_{a(\text{RAS})\text{MAX}}$.

Table 2.4 Maximum multiplex time

Type number	t_{MUX}	$t_{d(\text{RAS-CAS})}$	$t_h(\text{RAS-RA})$	$t_{\text{SU}}(\text{CA-CAS})$
M5K4116P, S-2	35 ns	50 ns	20 ns	- 10 ns
M5K4116P, S-3	45 ns	65 ns	25 ns	- 10 ns
M5K4116P, S-4	55 ns	85 ns	35 ns	- 10 ns

Note 3: $t_T = 5\text{ns}$

2. The delay time $t_{d(\text{RAS-CAS})}$ is set greater than the maximum value of the limits. In this case the internal inhibition of $\overline{\text{CAS}}$ has already been released, so that the internal $\overline{\text{CAS}}$ control signals are controlled by the externally applied $\overline{\text{CAS}}$, which also controls the access time.

Fig. 2.8 Read access time vs delay time

Data Input

Data to be written into a selected cell is strobed by the later of the two negative transitions R/W input and $\overline{\text{CAS}}$ input. Thus, when the R/W input makes its negative transition prior to the $\overline{\text{CAS}}$ input (early write), the data input is strobed by the $\overline{\text{CAS}}$ input (early write), and the negative transition of the $\overline{\text{CAS}}$ is set as the reference point for setup and hold times. In the read-write or read-modify-write cycles, however, when the R/W input makes its negative transition after the $\overline{\text{CAS}}$, the R/W negative transition is set as the reference point for set-up and hold times.

Data Output Control

Fig. 2.9 Read cycle

The output of the M5K4116P, S is in the high-impedance state when the $\overline{\text{CAS}}$ is high. When the memory cycle in progress is a read, read-modify-write, or a delayed-write cycle, the data output will go from the high-impedance state to the active condition, and the data in the selected cell will be read. This data output will have the same polarity as the input data. Once the output has entered the active condition, this condition will be maintained until the $\overline{\text{CAS}}$ goes high, irrespective of the condition of the $\overline{\text{RAS}}$ (to a maximum of 10 μs).

The output will remain in the high-impedance state throughout the entire cycle in an early-write cycle.

Fig. 2.10 Write cycle

Table 2.5 Output state in write cycle

Operation mode	Output state
Early write	High impedance
Read-write, read-modify-write	Data valid
Others	Unspecified

These output conditions of the M5K4116P, S, which can readily be changed by controlling the timing of the write pulse in a write cycle, and the width of the $\overline{\text{CAS}}$ pulse in a read cycle, offer capabilities for a number of applications, such as the following.

1. Common I/O Operation

If all write operations are performed in the early-write mode, input and output can be connected directly to give a common I/O data bus.

2. Data Output Hold

The data output can be held between read cycles, without lengthening the cycle time, until the next cycle commences. This enables extremely flexible clock-timing settings for $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$.

3. Two Methods of Chip Selection

Since the output is not latched, the $\overline{\text{CAS}}$ is not required to maintain the output of selected chips in the matrix in a high-impedance state. This means that the $\overline{\text{CAS}}$ and/or the $\overline{\text{RAS}}$ can both be decoded for chip selection.

4. Extended-Page Boundary

By decoding $\overline{\text{CAS}}$, the page boundary can be extended beyond the 128 column locations on a single chip. In this case, the $\overline{\text{RAS}}$ must be applied to all devices.

Page-Mode Operation

This operation allows for multiple-column addressing at the same row address, and eliminates the power dissipation associated with the negative-going edge of the $\overline{\text{RAS}}$ because once the row address has been strobed, the $\overline{\text{RAS}}$ is maintained. Also, the time required to strobe in the row address for the second and subsequent cycles is eliminated, thereby decreasing access and cycle times.

Refresh

Refreshing of the dynamic cell matrix is accomplished by performing a memory operation at each of the 128 row-address locations within a 2ms time interval. Any normal memory cycle will perform the refreshing, and the $\overline{\text{RAS}}$ -only refresh offers a significant reduction in operating power.

Power Dissipation

Most of the circuitry in the M5K4116P, S is dynamic, and most of the power is dissipated when the addresses are strobed. Both the $\overline{\text{RAS}}$ and the $\overline{\text{CAS}}$ are decoded and applied to the M5K4116P, S as chip-select in the memory system, but if the $\overline{\text{RAS}}$ is decoded, all unselected devices go into stand-by independent of the $\overline{\text{CAS}}$ condition, minimizing system power dissipation.

Stand-By Current-Refresh Only

The I_{DDSB} (stand-by current of V_{DD}) and the I_{BBSB} (stand-by current of V_{BB}) are calculated by the following equations.

1. $\overline{\text{RAS}}/\overline{\text{CAS}}$ refresh

$$I_{\text{DDSB}} = I_{\text{DD1(AV)}} \times \left\{ 128 \times \frac{t_{\text{C}}}{t_{\text{C(REF)}}} \right\} + I_{\text{DD2}} \times \left\{ 1 - \left(128 \times \frac{t_{\text{C}}}{t_{\text{C(REF)}}} \right) \right\} \dots \text{Eq. 2}$$

$$I_{\text{BBSB}} = I_{\text{BB1(AV)}} \times \left\{ 128 \times \frac{t_{\text{C}}}{t_{\text{C(REF)}}} \right\} + I_{\text{BB2}} \times \left\{ 1 - \left(128 \times \frac{t_{\text{C}}}{t_{\text{C(REF)}}} \right) \right\} \dots \text{Eq. 3}$$

Assuming that $t_{\text{C}}=375\text{ns}$, $I_{\text{DD1(AV)}}=35\text{mA}$,

$I_{\text{BB1(AV)}}=200\mu\text{A}$, $I_{\text{DD2}}=1.5\text{mA}$,

$I_{\text{BB2}}=100\mu\text{A}$, $t_{\text{C(REF)}}=2\text{ms}$,

we can obtain following results:

$$I_{\text{DDSB}} = 35\text{mA} \times 0.024 + 1.5\text{mA} \times 0.976 = 2.3\text{mA}$$

$$I_{\text{BBSB}} = 200\mu\text{A} \times 0.024 + 100\mu\text{A} \times 0.976 = 102\mu\text{A}$$

Fig. 2.11 Distribution of average I_{DD}

Fig. 2.12 Distribution of stand-by I_{DD}

2. \overline{RAS} -only refresh

$$I_{DDSB} = I_{DD3(AV)} \times \left\{ 128 \times \frac{t_C}{t_{C(REF)}} \right\} + I_{DD2} \times \left\{ 1 - \left(128 \times \frac{t_C}{t_{C(REF)}} \right) \right\} \dots \text{Eq. 4}$$

$$I_{BBSB} = I_{BB3(AV)} \times \left\{ 128 \times \frac{t_C}{t_{C(REF)}} \right\} + I_{BB2} \times \left\{ 1 - \left(128 \times \frac{t_C}{t_{C(REF)}} \right) \right\} \dots \text{Eq. 5}$$

Assuming that $I_{DD3(AV)} = 27\text{mA}$, $I_{BB3(AV)} = 200\mu\text{A}$, we obtain the following results:

$$I_{DDSB} = 27\text{mA} \times 0.024 + 1.5\text{mA} \times 0.0976 = 2.1\text{mA}$$

$$I_{BBSB} = 200\mu\text{A} \times 0.024 + 100\mu\text{A} \times 0.0976 = 102\mu\text{A}$$

Stand-by current is about 2.1mA. Therefore, by using low-power refresh and external circuits, it is possible to use a battery back-up system.

Power Supplies

Although the M5K4116P, S require no particular power-supply sequencing so long as the devices are used within the limits of the absolute maximum ratings, it is recommended that the V_{BB} supply be applied first and removed last. V_{BB} should never be more positive than V_{SS} when power is applied to V_{DD} . Generally, when V_{DD} is applied and V_{BB} is not applied, stand-by current is larger than that in the normal state. Table 5 shows this effect.

Some eight dummy cycles are necessary after power is applied to the device before memory operation is achieved. Dummy cycles must be executed by the $\overline{RAS}/\overline{CAS}$ refresh cycles or \overline{RAS} -only refresh cycles.

Table 2.6 Change of stand-by current

Device Condition	#1		#2		#3		#4		Unit
	$I_{DD1(AV)}$	I_{DD2}	$I_{DD1(AV)}$	I_{DD2}	$I_{DD1(AV)}$	I_{DD2}	$I_{DD1(AV)}$	I_{DD2}

2.2 16K-BIT DYNAMIC RAM APPLICATION

APPLICATIONS FOR DYNAMIC RAM

Dynamic RAM (Random-Access Memory)s can be very effective components in the implementation of reliable, high-performance, low-cost memory systems. However, these devices have several requirements that should be considered.

Bit-Cell Structure

First, consider the dynamic memory bit cell, which is quite unlike the cell of a static RAM. Fig. 2.13 shows a typical single-transistor memory bit cell. The bit cell consists of a transistor and a capacitor that constitute a "sample and hold" circuit.

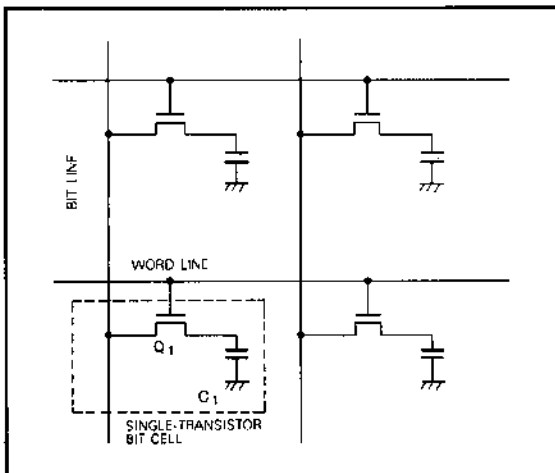

Fig. 2.13 Single-transistor memory bit cell

During the write operation, the selected word line is brought to an active state (high). This causes the bit cell transistor Q_1 to turn "On" and the data that is placed on the bit line is stored in the capacitor C_1 . The stored data is retained even if transistor Q_1 turns "Off".

During the read operation, the selected line is brought to an active state (high) again, and the capacitor voltage is placed on the bit line. At this time, the read-out data is amplified and rewritten on the capacitor internally.

Because of the theory governing dynamic memory storage, capacitor charge in the cell will gradually leak off, and the stored data will be lost.

For example, a 1nA leakage current discharging a 1pF capacitor results in a voltage change of 1V per ms. The storage time of M5K4116P, S is shown in Fig. 2.14. If data is to be retained for longer than the self-discharge time of the cell storage capacitor, typically 2ms, the data must be sensed before it is lost and then restored to its original voltage level.

Fig. 2.14 Storage time vs. ambient temperature

Refresh

Thus one can see that the refresh function is a very important requirement for a charge-storage memory, i.e., a dynamic RAM. The dynamic memory controller must assure that every bit cell is refreshed periodically enough to maintain data integrity. The refresh interval is specified by the vendor, and a typical requirement is that each bit cell be refreshed every 2ms.

The M5K4116P, S are 16 384-bit memories constructed with 128 rows and 128 columns. All columns in a single row in an array are refreshed simultaneously. This means that the user must supply 128 refresh cycles each 2ms.

In order to supply the refresh row address, a refresh counter (7 bits) is required and is incremented after each refresh cycle. A "two inputs to one output" multiplexer is also used to multiplex either the system-supplied memory address or the refresh counter-supplied address onto the dynamic memory row address inputs.

Refresh Techniques

In most memory systems it is difficult to guarantee that normal memory operations will cause all the rows within a memory to be sensed within the specified refresh interval. For this reason, most dynamic memory systems have special circuitry that will cause all rows of memory cells to be sensed within the 2ms interval.

There are three commonly used techniques for refreshing the memories. The first is "burst mode refresh" where all memory accesses are inhibited for a fixed period of time while all rows are continuously accessed. This mode is shown in Fig. 2.15 (a). The second is "cycle steal mode," where a single memory cycle is periodically stolen from the processor in order to refresh a single row. This mode is shown in Fig. 2.15 (b). The third is called "invisible or trans-

(M5K4116P, S)

parent mode," where refresh cycles are introduced at the times when the memory is not being accessed and thus refresh is invisible to the processor. (The processor sees no delay due to the refresh function.) This mode is shown in Fig. 2.15 (c). The memory cycle of the invisible refresh mode is generally longer than that of the first or second method because single memory access continues after single memory access.

Design Example

In designing dynamic memory systems, it is important to decide whether the memory refresh will be synchronous with the processor or asynchronous. In synchronous refresh, the designer uses a system clock to trigger the refresh logic. In asynchronous refresh, however, the designer must provide for a local timer to trigger the refresh and memory access arbiter.

This example illustrates the asynchronous refresh method which is more popular than the synchronous refresh in interfacing dynamic RAMs to microprocessors. The memory controller block diagram is shown in Fig. 2.16. There are two controllers which access the memory. One is the microprocessor, and the other is refresh timer which requests a memory refresh every 15.6 μ s (MAX). The memory access arbiter decides to which request the memory cycle is allocated. If the two controllers generate the request simultaneously, the arbiter allocates the memory cycle to the refresh timer.

Memory timing logic generates the memory clock timing (i.e. RAS, CAS, R/W) in accordance with the memory cycles. This timing is shown in Fig. 2.18. Three multiplexers are used in the circuit of Fig. 2.17. In the normal memory cycle, the row address (ADR0~ADR6) or column address (ADR7~ADRD) is multiplexed by MPXCNT and CPU ADREN. In the refresh cycle, the refresh address is present at MA0~MA6, which is gated by REFADREN.

The refresh controller in Fig. 2.17 is also used in 64K dynamic RAM applications by changing the refresh address counter and microprocessor address multiplexer.

(M5K4116P, S)

Power Distribution and Decoupling Techniques

It should always be remembered that dynamic memories, while appearing to be rather simple digital devices, are in fact highly complex analog systems. They include differential sensing amplifiers that must detect deci volt signals buried in noise and must operate in tens of nano-seconds. For these reasons, the designer should respect the complexity involved and take the steps necessary to ensure a trouble-free design.

The layout of dynamic memories is of special importance. Typical I_{DD} , I_{BB} and I_{SS} current waveforms for the M5K4116P, S are shown in our data sheets. Distribution and decoupling techniques must be used to suppress these noises, which can cause data loss.

The layout should have an effectively gridded power-supply distribution network to supply adequate current and to minimize inductive effects. The distribution of circuit grounding is most important in reducing ground noise and inductive effects, and to provide a ground plane for the signal lines. An example of the power grid of the M5K4116P, S is shown in Fig. 2.20, in which the decoupling capacitors are not shown.

In order to increase the effectiveness of the power grid, decoupling capacitors should be used. The capacitors required fall into two categories. The first consists of capacitors of small size and low inductance such as monolithic and other ceramic capacitors, which are adequate for suppression of transient noise. The second type consists of larger bulk capacitors used to prevent power supply drop. These also should be included within the memory array for good distribution.

The decoupling capacitors used in the memory array should be of a type that exhibits good high-frequency characteristics. It is recommended that a $0.1\mu\text{F}$ ceramic capacitor be connected between V_{DD} and V_{SS} at every other device in the memory array. It is also recommended that a $0.1\mu\text{F}$ ceramic capacitor be connected between V_{BB} and V_{SS} at every other device in the array, preferably the devices alternate to the V_{DD} decoupling. Decoupling of the V_{CC} is fairly noncritical. The capacitors are connected at the top and bottom of each column of memories.

In addition to the ceramic capacitor, it is recommended that a $2\sim 5\mu\text{F}$ tantalum or equivalent capacitor be connected between V_{DD} and V_{SS} adjacent to the array for each group of 16 memory devices. Use of a slightly smaller-value bulk capacitor is also recommended between V_{BB} and V_{SS} . An example of capacitor placement is shown in Fig. 2.21.

Note 7 The dotted lines show the soldered side of the P.C. board.
Fig. 2.20 Suggested power grid for M5K4116P, S

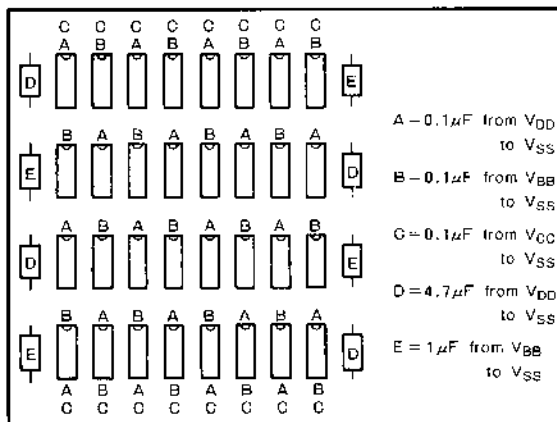

Fig. 2.22 Effective capacitor placement for the M5K4116P, S

Signal Lines Effects

By carefully laying out the circuit to minimize signal path length, one can reduce effects due to the transmission-line properties of the PC board. However, this may not be sufficient. It is necessary to add a series-terminating resistor to the output of the clock driver in order to match line impedances and damp out reflections caused by mismatching between the driver's source impedance and the characteristic impedance of the line.

In order to avoid to cross talk problems, all signal lines should be kept as short as possible. This implies that the signal drivers and receivers should be physically close to the memory array.

64K-BIT DYNAMIC RAM

(M5K4164S, M5K4164NS)

3. 64K-BIT DYNAMIC RAM

3.1 Technology

Since the introduction of the 1K RAM in 1970, the development of dynamic RAM devices has progressed at a rate which has seen capacities multiplied by four in approximately two years, the latest stage of development being the 64K RAM.

Today's modern RAM devices take the user into consideration, and 64K dynamic RAMs which operate off a single 5V power supply are common.

We will describe here the new technology which made possible the development of a highly integrated, high-performance 64K RAM (Type M5K4164S) which operates from a single 5V supply.

Fig. 3.1 shows the cross-section of the cell structure with Table 3.1 summarizing a comparison of the basic parameters of the device with the 16K RAM.

Cell Structure and Process Technology

The M5K4164S 64K RAM makes use of the same two-level n-channel polysilicon gate process and one-transistor cell structure used in the triple power supply 16K RAM (M5K4116 P/S) which has been used in large quantities.

To achieve a high-density RAM, the masks are manufactured using electron beam technology.

In addition, the geometries on several critical levels of the M5K4164S are 2.5 to 3.0 μ m, necessitating the use of positive photo-resist (for resolution and delineation control) as well as dry-plasma processing at these critical levels.

Fig. 3.1 Hi-C structure memory cell cross-section

Table 3.1 Main Parameters

Parameter	16K RAM	64K RAM
Memory cell area	350 μ m ²	200 μ m ²
Chip area	16.3mm ²	31.3mm ²
Effective channel length	4 μ m	2 μ m
Gate oxide thickness	850 Å	430 Å
Diffused layer depth	1.0 μ m	0.5 μ m
Diffused layer width	4.0 μ m	3.0 μ m
Aluminum width	4.0 μ m	3.0 μ m

Substrate Bias Circuit

In order to facilitate the operation from a single 5V supply, the M5K4164S makes use of an on-chip substrate bias circuit. This bias circuit consists of a ring oscillator, driver circuit, charge pump circuit, and decoupling capacitors. The circuit supplies a bias to the substrate of approximately -3.5V for $V_{CC}=5V$ (Refer to Fig. 3.2).

The substrate bias circuit has the following functions.

1. It prevents destruction of storage data and disturbance of bipolar transistor operation caused by input undershoot which causes an injection of electrons from the input terminals to the substrate.
2. A reduction in the capacitance of the pn junction formed by the substrate and internal circuit nodes enables an increase in circuit operation speed.
3. The transistor threshold voltage (V_{TH}) modulation due to a bias substrate is reduced, resulting in increased circuit operating speed and stability.

Fig. 3.2 Substrate bias circuit

As shown in Fig. 3.3, the substrate bias for high values of V_{CC} is lower than for the standby mode due to the effect of increased impact ionization current. Adequate margin, however, is maintained against a value of V_{IL} min of -2V.

Reduced Power Consumption and Noise

For operation from a 5V supply, it is necessary to reduce the transistor threshold voltage, V_{TH} . This however invites error operation due to noise. For this reason, circuits required to operate from low voltages only make use of transistors with a low V_{TH} , while those requiring noise immunity are implemented with transistors having a high value of V_{TH} . This scheme insures stable operation.

To lower the peak circuit current, a significant problem in memory system design, and provide for high speed operation, the ratioless driver circuit shown in Fig. 3.4 was used.

With this circuit, the current flowing in transistors Q_1 and Q_2 for changes in the output waveform is practically zero.

Fig. 3.5 Peak current waveforms

Soft Error Reduction

Reduced pattern sizes and lower supply voltages for 64K RAM devices which result in smaller storage charges result in a higher susceptibility to alpha particles caused soft errors.

These soft errors are caused by alpha particles from minute amounts of uranium and thorium which are present in the IC package and decay. These particles cause the formation of electron-hole pairs in the substrate which collect on the surface and can destroy data.

All floating nodes of dynamic circuits are susceptible to such radiation caused errors and for RAM operation, errors can occur when such phenomena occur in the memory cells and bit lines (including the sense amplifier).

To prevent such soft errors, three approaches are possible.

1. Increase the stored charge in the memory cells.
 2. Increase the sense amplifier sensitivity and the bit line signal level.
 3. Prevent alpha particles from reaching the chip circuits.
- As described below the M5K4164S makes use of these techniques to reduce the effects of alpha radiation.

(M5K4164S, M5K4164NS)

Bootstrapped Word Line Voltage

Designs of 64K dynamic RAM devices which must operate on 5V supplies must strive to write data into memory with the voltage V_{CC} as well as increase the charge stored in the memory cells in order to reduce the effects of soft errors. This in effect means raising the word line voltage to above the value of $V_{CC} + V_{TH}$ for write and read operations.

Previously this increase in voltage was accomplished by means of the coupling capacitance between the word line and the delay circuit. However, the increased capacitance resulted in a slow risetime of the word line voltage to V_{CC} , as well as increased power consumption. To eliminate these problems a circuit design such as that shown in Fig. 3.6 is used. The transistor Q_2 is kept off until the word line voltage reaches V_{CC} . This has the word line charge capacity. C_2 is then charged by means of transistor Q_3 after which Q_2 is turned on to connect the word line and C_2 . The use of this circuit enables increase of the word line voltage without sacrificing operating speed and power consumption, thereby cutting soft error rates by 90%.

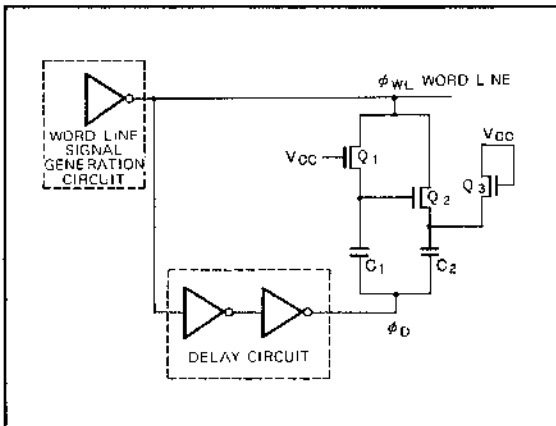

Fig. 3.6 Bootstrapped word line voltage generation circuit

High Capacity (Hi-C) Memory Cell

The increase of memory cell stored charge requires an increase in the memory cell capacitance C_S . Limited chip area, however, places restrictions on the size of the memory cell itself. For this reason the Hi-C structure shown in Fig. 3.1 was used. This cell structure makes use of the normal silicon oxide layer and the p^+ and n^+ junction capacitance. The process for Hi-C memory cell structure requires two additional ion implantation steps and involved the risk of deterioration of the refresh time, an important characteristic of a dynamic RAM device. By selecting the ion implantation level properly, the junction capacitance can be increased without deterioration in the refresh time characteristic. For Hi-C structured cells, a portion of the minority carriers formed in the p^+ layer are recombined, resulting in an effective reduction in soft errors. Such ion implantation

has achieved a 30% increase in the memory cell capacitance and a reduction in soft error rate to 1/12 of the error rate of a normally structured cell, as shown in Fig. 3.7.

Fig. 3.7 Soft error rate dependency on supply voltage (V_{CC})

Sense Amplifier Circuit

Increasing the sensitivity of the sense amplifier circuit is another effective method of reducing soft errors. Fig. 3.8 shows part of the sense amplifier circuit used by Mitsubishi Electric. High sensitivity with respect to the control signals ϕ_1 , ϕ_2 , and ϕ_3 plays an important role in this amplifiers operation. After the data read from the memory cell is passed to the sense amplifier, the ϕ_2 signal is controlled to separate the bit line and cut off the noise that is present on the bit line when sensing begins. Smooth sensing begins with the signal ϕ_1 applied so that the minute potential difference is amplified. Next, ϕ_2 is applied and amplified at high speed. By careful adjustment of the timing of the three control signals ϕ_1 , ϕ_2 , and ϕ_3 , detection of potential differences as low as 30mV can be achieved without sacrificing speed in this sense amplifier circuit.

64K-BIT DYNAMIC RAM

(M5K4164S, M5K4164NS)

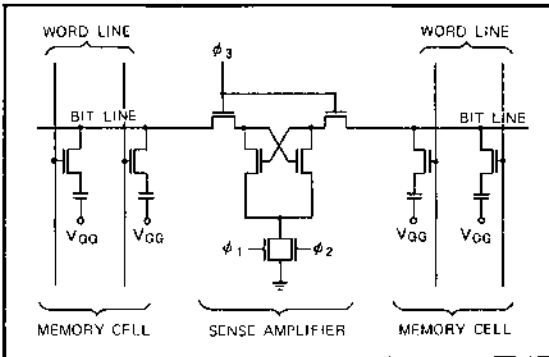

Fig. 3.8 Sense amplifier circuit

128 Refresh Method

When the sense amplifiers sensitivity (offset) and other factors are considered, it is clear that it is important to maximize the read voltage applied from the memory cell to the bit line. The electrical charge, Q , read from the memory cell determines the voltage change ΔV by the following relationship.

$$\Delta V \approx Q/C_B \text{ (for } C_B \gg C_S)$$

where C_B is the bit line and C_S is the memory cell capacitance.

From this relationship it is seen that to make ΔV large C_B must be made small. To satisfy this condition the 128 refresh method is used to implement a single bit line with 64 memory cells, a technique which reduces the length of the bit line. Fig. 3.9 shows the chip layout. The memory cells are broken into 64x256 bit units which are narrow, long blocks. The column decoders are located in three blocks totalling 256 decoders at the end of the bit line.

Using this arrangement, the bit line capacitance can be minimized.

Chip Coating

In addition to circuit and device structure improvements aimed at reducing soft errors, the design goal of 10^{-6} (device hours) required further improvements. The effective range of travel of 5MeV alpha particles in organic resin is a quite short 30~50 μ m, enabling almost all alpha particles to be shut out by coating the silicon chip surface with such a resin to a thickness of about 40 μ m.

When this is done, however, alpha particles emitted from the coating material itself cause errors, making material selection critical. The polyimide resin chosen exhibits an alpha radiation level of 0.005 α /(cm²·hour), below the measurement sensitivity of an ion chamber. This is low enough that the resulting alpha particle generation level is 1/10 or less that of the package material itself.

Before ceiling the package, this material is coated to a depth of 40 μ m resulting in at least an expected 90% reduction in alpha particles over non-coated chips.

System evaluations of the M5K4164S treated in such a manner indicate that 10^{-7} /(device hours) for soft error has been achieved.

3.2 Functional Description

Introduction

The MSK4164S is a 64K-bit dynamic RAM which operates off a single 5V supply and has a refresh function built in by means of pin 1. It can be used in a wide range of applications from large mainframes to microcomputers.

This section presents a functional description of the MSK4164S and examines how it can be used in design of a memory system.

Block Diagram

Fig. 3.10 shows the block diagram of the MSK4164S. To preserve the refresh cycle used for 16k dynamic RAM devices, two 32k (two 32k [128 rows (refresh address) x 256 columns] blocks were arranged one on top of the other.

In the center of each block is located 256 sense amplifiers making a total of 512 amplifiers in all.

On one end of each of these two array blocks, is located one row of row decoder.

To prevent crosstalk between the column address lines and bit lines, the column decoder are located at the ends of the bit lines on the opposite side from the sense amplifiers. A total of three rows of column decoders are used.

The central column decoder is used commonly by the two blocks.

Memory Cell

As show in Fig. 3.11, the memory cell consists of one transistor and one capacitor. Data is stored as a one or zero depending upon the amount of electrical charge stored in the capacitor through the transistor Q.

Because leakage current would result in the stored charge of the cell being reduced with time, the data must be refreshed within 2ms.

Fig. 3.11 Memory cell

Fig. 3.10 Block diagram

(M5K4164S, M5K4164NS)

Clock Timing

The M5K4164S has four clock inputs; \overline{RAS} , \overline{CAS} , \overline{W} , \overline{REF} . Among these, \overline{RAS} and \overline{CAS} are the basic clock inputs for the memory operation. The \overline{RAS} input is generally used for memory cell data amplification and refresh operation while the \overline{CAS} is used for data read and write operations only.

To enable the design of a memory system with a large timing margin, it is necessary to know the timing relationships between these two clock inputs and the internal clock signals generated by these clocks.

Fig. 3.13 shows the timing parameters of the \overline{RAS} and \overline{CAS} clocks while Fig. 3.14 and 3.15 show their relationships to the internal clock timing.

For read or write operations, \overline{RAS} goes low after which the falling edge of \overline{CAS} initiates the cycle.

After the read or write is completed, both signals return to a high level and the precharging operation is performed for the next cycle.

For this timing relationship to work, the external \overline{RAS} clock must follow the changes of the internally generated \overline{RAS} clock. To simplify the setting of the timing relationships of the external \overline{RAS} and \overline{CAS} clocks, the internal \overline{CAS} clock is controlled by the external \overline{RAS} clock.

Fig. 3.12 Internal clock generator of \overline{RAS} and \overline{CAS}

Fig. 3.13 \overline{RAS} , \overline{CAS} timing

(M5K4164S, M5K4164NS)

(1) $\overline{\text{CAS}}$ Falling Edge Timing (Fig. 3.14)

The memory system design must be such that the falling edge timing of $\overline{\text{CAS}}$ does not critically affect the access time. In other words as shown by the solid line in Fig. 3.14, the internal ϕ_{CAS} phase is prevented by the delay phase ϕ_1 from approaching $t_{\text{d(RAS-CAS) max}}$. This type of operation is referred to as gated $\overline{\text{CAS}}$.

This gated $\overline{\text{CAS}}$ feature permits $\overline{\text{CAS}}$ to be activated at anytime between the minimum and maximum value of $t_{\text{d(RAS-CAS)}}$ without affecting access time [$t_{\text{a(RAS)}}$].

For gated $\overline{\text{CAS}}$ operation, if the generation of internal clock phase ϕ_{CAS} is delayed, the effective pulse width of ϕ_{CAS} is reduced. For this reason, the rising edge of $\overline{\text{CAS}}$ is specified by $t_{\text{h(RAS-CAS)}}$ which is reference to $\overline{\text{RAS}}$ rather than $t_{\text{w(CASL)}}$. This applies to the column address, $\overline{\text{W}}$ and $\overline{\text{D}}$ inputs hold time as well.

As shown by the dotted line in Fig. 3.14, if $\overline{\text{CAS}}$ falls to a low level after $t_{\text{d(RAS-CAS) max}}$, the ϕ_{CAS} phase is generated upon the falling edge of $\overline{\text{CAS}}$.

The minimum and maximum values of $t_{\text{d(RAS-CAS)}}$, the delay time $\overline{\text{RAS}}$ to $\overline{\text{CAS}}$, are specified for the M5K4164S. Operation within the $t_{\text{d(RAS-CAS) max}}$ limit ensures that the access time for the device is guaranteed. This value may be exceeded without causing data storage or reading errors but the access time will be increased.

Fig. 3.14 The timing relationship of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ falling edges to internal clock signals (gated $\overline{\text{CAS}}$ operation)

(2) $\overline{\text{CAS}}$ Rising Edge Timing (Fig. 3.15)

As shown in Fig. 3.15, the internally generated $\overline{\text{CAS}}$ circuit precharge signal $\phi_{\overline{\text{CAS}}}$ is generated with a timing that is related to the relationship between $\overline{\text{RAS}}$ and the $\overline{\text{CAS}}$ rising edge.

For a $\overline{\text{CAS}}$ rising edge occurring before the $\overline{\text{RAS}}$ rising edge, $\phi_{\overline{\text{CAS}}}$ is generated with the $\overline{\text{CAS}}$ rising edge as a reference point (as shown in Fig. 3.15 as a solid line). If however the $\overline{\text{CAS}}$ rising edge occurs after that of $\overline{\text{RAS}}$, $\phi_{\overline{\text{CAS}}}$ is generated with the $\overline{\text{RAS}}$ rising edge as a reference (shown as dotted line in Fig. 3.15).

However, the data in the output buffer is cleared upon the occurrence of the rising edge of $\overline{\text{CAS}}$ regardless of the state of $\overline{\text{RAS}}$. The required pulse width for clear is $t_{\text{w(CASH)}}$.

In this manner, the output data can be maintained for a long period while the internal precharge width is made large.

As described above, if the $\overline{\text{CAS}}$ rising edge occurs after that of $\overline{\text{RAS}}$, the internal $\overline{\text{CAS}}$ pulse width becomes not $t_{\text{w(CASL)}}$ but $t_{\text{h(CAS-RAS)}}$. Consideration should be given to this point in system design.

Fig. 3.15 Relationship of $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ rising edges to internal clock timing

(M5K4164S, M5K4164NS)

Address Timing

Addressing of any one of the 65,536 memory cells of the M5K4164S requires the internal latching of two 8-bit multiplexed address (A_0 to A_7) by means of clocks \overline{RAS} and \overline{CAS} . First, the row address is latched by the falling edge of \overline{RAS} . This selects 512 memory cells from the total of 65,536 memory cells. Fig. 3.16 shows the timing relationships for this operation.

Fig. 3.16 Row address latching timing

The setup time $t_{su}(RA-RAS)$ and hold time $t_h(RAS-RA)$ are specified with the \overline{RAS} falling edge as a reference point.

The falling edge of \overline{CAS} latches the column address. This selects one cell from among the 512 cells selected by \overline{RAS} . Fig. 3.17 shows the timing relationships for this operation. The setup time $t_{su}(CA-CAS)$ and the hold time $t_h(CAS-CA)$ are specified with the falling edge of \overline{CAS} as a reference, while the hold time $t_h(RAS-CA)$ is specified with the falling edge of \overline{RAS} as a reference point.

Fig. 3.17 Column address latching timing

For these operations two timing parameters must be considered. One is the column address setup time $t_{su}(CA-CAS)$ which is specified as minus 5 ns, minimum. This means that the column address may be input anytime up to 5 ns after the \overline{CAS} falling edge.

The other parameter is the column address hold time $t_h(RAS-CA)$. For the previously described gated CAS operation, if \overline{RAS} to \overline{CAS} delay time $t_d(RAS-CAS)$ is set between the specified minimum and maximum values, the time from \overline{RAS} , $t_h(RAS-CA)$ and time from \overline{CAS} , $t_h(CAS-CA)$ must both be satisfied as the column address hold time. This applies to both the \overline{W} and D signals to be described later.

The time required to switch from row address to column address is referred to as the multiplex time (t_{mux}). This timing is shown in Fig. 3.18.

Fig. 3.18 Address multiplex timing

The multiplex time t_{mux} is given by the following expression:

$$t_{mux} = t_d(RAS-CAS) - t_T - t_h(RAS-RA) - t_{su}(CA-CAS) \dots(1)$$

As long as the access time, $t_a(RAS)$ from \overline{RAS} does not exceed the maximum value, the following expression determines the maximum value of t_{mux} is achieved by the following conditions.

$$\begin{aligned} t_d(RAS-CAS) &= \text{maximum} \\ t_h(RAS-RA) &= \text{minimum} \\ t_{su}(CA-CAS) &= \text{minimum} \end{aligned}$$

Table 3.2 shows actual values of t_{mux} maximum for $t_T = 5\text{ns}$.

Table 3.2 Maximum Multiplex Time

Parameter	$t_{MUX \text{ max}}$	$t_d(RAS-CAS)$	$t_h(RAS-RA)$	$t_{su}(CA-CAS)$
M5K4164S -15	55ns	75ns	20ns	- 5ns
M5K4164S -20	75ns	100ns	25ns	- 5ns

If the timing is set to satisfy the above described, operation is guaranteed for both read and write functions. To simplify the following description, the timing parameters for address inputs has been eliminated unless absolutely required.

Read Cycle

Fig. 3.19 shows the timing parameters for the read cycle.

Fig. 3.19 Read cycle timing

In this read cycle, \overline{RAS} and \overline{CAS} are made active, and the \overline{W} input is set to a high level. The setup time, $t_{su}(R-CAS)$ before \overline{CAS} , resulting in output of the data stored in the memory cell at pin Q. The time for the falling edge of \overline{RAS} and \overline{CAS} to the output is defined as the RAS access time $t_b(RAS)$ and the \overline{CAS} access time $t_a(CAS)$ respectively.

The RAS access time depends on the \overline{RAS} to \overline{CAS} delay time, $t_d(RAS-CAS)$. The relationship for the $t_b(RAS)$ and $t_d(RAS-CAS)$ is shown in Fig. 3.19.

As can be seen from this figure, by setting $t_d(RAS-CAS)$ before t_d for gated \overline{CAS} operation, $t_b(RAS)$ does not depend on the value of $t_d(RAS-CAS)$ and is constant.

For $t_d(RAS-CAS)$ set after t_d , $t_b(RAS)$ depends upon the value of $t_d(RAS-CAS)$. For this condition, $t_b(RAS)$ is given by the following expression.

$$t_b(RAS) = t_d(RAS-CAS) + t_a(CAS) \quad \dots (2)$$

Equation (2) expresses only the electrical characteristics of the RAM device, the guaranteed access time being given by the following expression.

Fig. 3.20 Dependency of $t_b(RAS)$ on $t_d(RAS-CAS)$

$$t_b(RAS) \leq t_{d(RAS-CAS) \max} + t_{a(CAS) \max} \quad \dots (3)$$

In equation (3), for a value of $t_{d(RAS-CAS)}$ greater than the maximum value, $t_b(RAS)$ increases by the increased amount only.

During a read operation when the output is active, inputs \overline{RAS} and \overline{W} have no effect on the output. Only raising \overline{CAS} to a high level will put the output in the high-impedance state.

The time from the rising edge of \overline{CAS} until the output goes into the high-impedance state is defined as the output disable time ($t_{dis}(CAS)$). This time, $t_{dis}(CAS)$ is the period for the RAM output to go to the open state and should be distinguished from that time the output states to go to V_{OH} and V_{OL} .

The read cycle parameters $t_h(CAS-R)$ and $t_h(RAS-R)$ determine the read cycle ending time. Operation is guaranteed if either of these parameters are satisfied.

Write Cycle

Three types of write cycles are specified; early write, read write and read modify write.

(1) Early Write Cycle

Fig. 3.21 illustrates the timing relationship for this cycle.

This cycle is selected for applications such as I/O common applications in which the output is held at high impedance during the writing of data into the memory cell.

This cycle is executed by causing the \overline{W} input to fall before \overline{CAS} .

The \overline{W} and D inputs are latched by \overline{CAS} , then the writing of data is executed, the \overline{W} and D input timing parameters $t_{su}(W-CAS)$, $t_{su}(D-CAS)$, $t_h(CAS-W)$, and $t_h(CAS-D)$ are determined by the falling edge of \overline{CAS} as a reference point.

Two points here are worthy of consideration. First is the write pulse setup time $t_{su}(W-CAS)$. This parameter is specified as minus 10ns, minimum.

The significance of this is that \overline{W} input may occur anytime within after 10ns of the falling edge \overline{CAS} .

However, should the \overline{W} input falling edge occur after \overline{CAS} , the rising edge of W is determined not by $t_h(CAS-W)$, but by $t_w(W)$.

The other point for consideration is setting $t_d(RAS-CAS)$ between the minimum and maximum values. For this condition, gated \overline{CAS} operation requires that as hold time the time from \overline{RAS} for the \overline{W} and D input, $t_h(RAS-W)$ and $t_h(RAS-D)$ and time from \overline{CAS} , $t_h(CAS-W)$ and $t_h(CAS-D)$ both must be satisfied.

(M5K4164S, M5K4164NS)

Fig. 3.21 Early write cycle timing

(2) Read Write Cycle Timing

This cycle is used in applications where data is to be read out of memory while new data is being written into a memory cell.

The timing parameters for this read write cycle are shown in Fig. 3.22.

For this type of cycle, the \overline{W} input signal falls after $t_d(RAS-W)$ min and $t_d(CAS-W)$ min.

The data read timing is the same as the read cycle. Since the read data is latched into an output buffer, \overline{W} input can

be made active without disabling the output.

Since the D input is latched by the falling edge of the \overline{W} input, the \overline{W} input falling edge is determined as a reference point for the D input setup time $t_{su}(D-W)$ and hold time $t_h(W-D)$.

Data is written into the memory cell between the time the \overline{W} input signal falls and \overline{RAS} and \overline{CAS} rise. This time is specified as $t_h(W-RAS)$ and $t_h(W-CAS)$ and both of these must be satisfied.

Fig. 3.22 Read write cycle timing

(M5K4164S, M5K4164NS)

(3) Read Modify Write Cycle

This cycle is used in applications such as ECC (see section on ECC) on which memory cell data is read and verified for correctness, the correct data being written into the cell if an error is detected. Fig. 3.23 shows the timing parameters of the read modify write cycle.

The RAM operation is the same as the previously described read write cycle except that after the data is read, data is written so the cycle is slightly extended.

The minimum time for the read modify write cycle is given by the following expression.

$$t_{CRMW \min} = t_{a(RAS) \max} + t_{MOD} + t_{h(W-RAS) \min} + t_{w(RASH) \min} + 3t_T \quad \dots (4)$$

In equation (4), t_{MOD} is the time required for incorrect data to be rewritten correctly, and is a function of system design. In the device specifications $t_{CRMW \min}$ is specified for $t_{MOD} = 0$.

As previously described, the M5K4164S write cycle mode is determined by the \overline{W} input falling edge timing. This falling edge timing does not limit the operation of the RAM but merely controls the output state. If the \overline{W} input falling edge does not satisfy the conditions described for the three write modes, data will be written but the output state will be indeterminate.

Fig. 3.23 Read modify write cycle timing

(M5K4164S, M5K4164NS)

Page Mode Timing

Page mode operation is successive memory operations at multiple column locations within the same row address.

As with normal operation, page mode operation can be carried out in the read, early write, read write or read modify write modes. The timing parameters particular to the page mode of operation are shown in Fig. 3.23. The other parameters are the same as for normal cycles.

Fig. 3.24 Page mode cycle timing

To perform page mode read and write operations, the $\overline{\text{RAS}}$ low-level pulse width, $t_{w(\text{RASL})}$ must be increased, the maximum value being 10 μs . The high-level $\overline{\text{CAS}}$ pulse width, $t_{w(\text{CASH})}$ is specified separately for the normal mode cycle and page mode. For the page mode, the pulse width must be increased. For details refer to the specifications.

For page mode operation the hold time $t_{h(\text{CAS-RAS})}$ must be satisfied for even the last cycle, as shown in Fig. 3.24. This applies to $\overline{\text{W}}$ as well.

Refresh

Referring to the block diagram of Fig. 3.10, for each $\overline{\text{RAS}}$ cycle, one word line is selected for each of the upper and lower blocks, enabling access to 512 memory cells. Next,

the 512 sense amplifiers operate to amplify and refresh the cell data. Address signal A_7 (Row) has no connection with this refresh operation since it is used as a block select address for data read and write operations.

$\overline{\text{RAS}}$ Only Refresh Timing

$\overline{\text{RAS}}$ only refresh is performed by setting $\overline{\text{CAS}}$ to high which sets the output to high-impedance while refresh is performed.

Both distributed and burst mode refresh can be performed.

Fig. 3.25 shows the timing parameters for $\overline{\text{RAS}}$ only refresh operation.

Fig. 3.25 $\overline{\text{RAS}}$ only refresh timing

Hidden Refresh Timing

Hidden refresh is accomplished by setting $\overline{\text{CAS}}$ to low after a read cycle to hold the data in the valid state while refresh is performed.

Both distributed and burst mode refresh are possible. Fig. 3.26 shows the timing parameters for hidden refresh operations.

Fig. 3.26 Hidden refresh timing

Data latched in the output buffer by the read cycle is refreshed during the hidden refresh cycles by $\overline{\text{RAS}}$. Therefore output data is held indefinitely as long as hidden re-

freshing is continued.

Timing design is simplified because the $\overline{\text{W}}$ may be changed in any state during hidden refreshing.

Refresh Operations Using Pin 1

To simplify the refresh operation, a function absolutely essential to dynamic RAM operation, two special refresh functions easier to use than the conventional $\overline{\text{RAS}}$ clock refresh have been provided.

These functions are automatic refresh and self refresh.

These special functions are implemented by an on-chip refresh counter, address multiplexer, and timer, along with the associated control circuitry. The following is an operational description of these circuits.

(1) Refresh Control Circuit

Fig. 3.27, is a block diagram of the refresh circuit which makes use of Pin 1. The control circuit controls not only the refresh counter, address multiplexer and timer as shown in Fig. 3.26, but $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ circuits as well.

Pin 1 refreshing is controlled externally by the $\overline{\text{REF}}$ input and internally by the $\overline{\text{RAS}}$ signal which is generated by the refresh control circuit.

During pin 1 refresh operations, the $\overline{\text{CAS}}$ circuit with the exclusion of the output buffer is inhibited to prevent data writing and reading.

Fig. 3.27 Refresh circuit block diagram

(M5K4164S, M5K4164NS)

(2) Refresh Counter Circuit

The M5K4164S on-chip refresh counter consists of a 7-bit toggle-type counter, the individual counter output being used as the refresh address bit.

For automatic refresh operations, the refresh counter counts up synchronized to the internal clock signal ϕ_w which is synchronized in turn to the $\overline{\text{REF}}$ input, 128 $\overline{\text{REF}}$ pulses required to cycle to the original state. For self refresh operation, the refresh counter is free-running with a period of from 12 to 16 μs , counting up in synchronous to the refresh request signal REFREQ (described afterwards). A complete cycle and return to the original state requiring that the $\overline{\text{REF}}$ input be held low for 16 μs x 128 = 2 ms.

The above described counting operation is performed approximately in synchronous with the refresh operation completion. The output of the refresh counter, Q_0 to Q_6 (refresh address) is held until the next refresh cycle, forming the address for the next cycle.

The refresh counter outputs are initialized by approximately 8 dummy cycles of $\overline{\text{RAS}}$, $\overline{\text{RAS/CAS}}$, or $\overline{\text{REF}}$. Therefore, no special initialization is required for this refresh counter.

However, the contents of the counter, that is the toggle counter flip-flop states, cannot be reset or preset externally during power up or dummy cycles.

For this reason, using both normal $\overline{\text{RAS}}$ and pin 1 refresh will cause the specified refresh time to be exceeded, and therefore should be avoided.

(3) Address Multiplexer

Fig. 3.28 shows the M5K4164S onchip address multiplexer.

The address multiplexer consists of two MOS transistors at the address buffer inputs and the associated control signals (MUX, $\overline{\text{MUX}}$).

During a normal cycle, $\overline{\text{MUX}}$ is high and MUX is low, so that only the external address A_0 to A_6 is input.

For pin 1 refresh operations, $\overline{\text{MUX}}$ is low and MUX is high so that the refresh counter output signals Q_0 to Q_6 only are input to the address buffer.

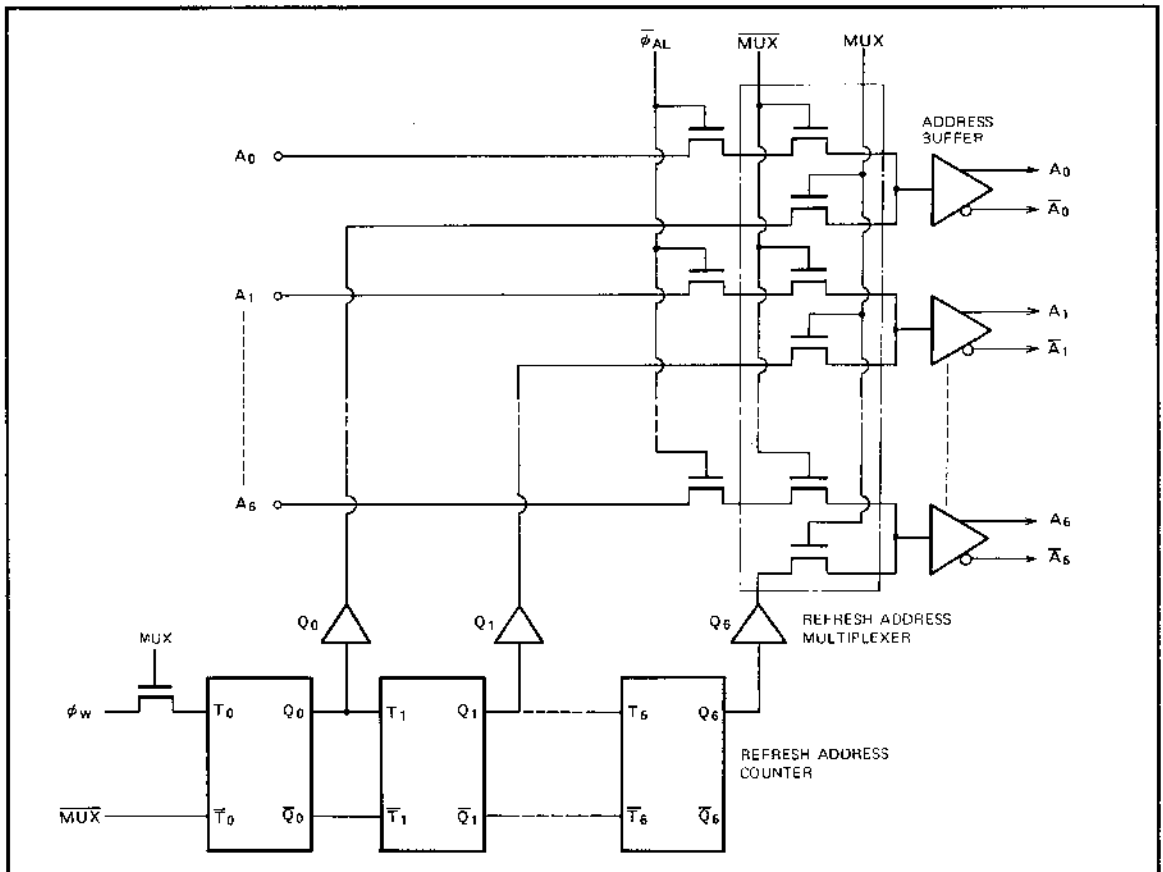

Fig. 3.28 Refresh address counter and multiplexer circuits

(M5K4164S, M5K4164NS)

(4) Timer Circuit

Fig. 3.29 shows the timer circuit block diagram while Fig. 3.30 illustrates its timing.

In the circuit of Fig. 3.29, the oscillator provides the substrate bias as well. The other circuits are active when $\overline{\text{REF}}$ is low.

When $\overline{\text{REF}}$ goes low, transistor Q_1 turns on, Q_2 turns off and the charge stored in C_2 passes through the rectifying circuit C_2 and Q_1 to discharge upon the falling edge of the oscillator output signal. The charge for one cycle of the oscillator output is proportional to the ratio of the capacitance of C_1 and C_2 .

The ratio of C_1 to C_2 is chosen such that the voltage across C_2 for an oscillator repetition period of 12 to 16 μs is approximately equal to the threshold voltage of the next gate. When the C_2 voltage reaches V_{TH} , the refresh request signal REFREQ goes active, causing the RAM refresh operation similar to the automatic refresh external signal $\overline{\text{REF}}$. When C_2 is charged by REFREQ, REFREQ goes low, causing a repetition of the above described timer operation.

As long as the $\overline{\text{REF}}$ signal is kept low, this operation will automatically continue refreshing all memory cells every 2 ms.

Fig. 3.29 Timer circuit block diagram

Fig. 3.30 Timer circuit timing

Automatic Refresh Timing

Automatic refresh is accomplished in the same manner as RAS only refresh but without providing the refresh address data.

Fig. 3.31 shows the timing of the automatic refresh operation.

Automatic refresh begins when $\overline{\text{REF}}$ is set to low $t_{w(RASH)}$ after $\overline{\text{RAS}}$ goes high.

Shortly after the refresh cycle begins the internal $\overline{\text{RAS}}$ signal begins to operate to strobe the refresh counter

output and perform the refresh.

The $\overline{\text{REF}}$ input is internally latched. When the refresh operation is complete an internal refresh complete signal causes the chip to be precharged. Therefore, it is not necessary to use the $\overline{\text{REF}}$ input to determine the precharge time greatly simplifying the timing design of $\overline{\text{REF}}$.

It is also possible to perform hidden refreshing by holding the $\overline{\text{CAS}}$ input low after a read cycle. The timing is very similar to the RAS hidden refresh operation timing.

Fig. 3.31 Automatic refresh timing

(M5K4164S, M5K4164NS)

Fig. 3.32 Self refresh timing

For details refer to the specifications.

Self Refresh Timing

Self refresh is generally used for battery backup of memory contents.

Fig. 3.32 shows the self refresh timing relationships from which it can be seen that they are quite similar to those of automatic refresh. Self refresh begins when \overline{REF} is set to low $t_{W(RASH)}$ after \overline{RAS} is set to high.

Shortly after the beginning of the refresh cycle, the internal \overline{RAS} signal begins to operate to strobe the refresh counter and perform the refresh operation.

As long as \overline{RAS} is high and \overline{REF} is low, the RAM will be automatically refreshed. This operation is repeated with a period of from 12 to 16 μ s. After 2ms, the refresh counter has gone through all of the row address, refreshing all of the memory cells. Self refresh ends when \overline{REF} is set to high but setting \overline{REF} to high may not terminate the internal operation of the circuit (refer to Fig. 3.30) so that one cycle time of $t_{d(REF-RAS)}$ is required between setting \overline{REF} to high and \overline{RAS} to low.

As with automatic refresh, hidden refreshing is possible. For details refer to the specifications.

Notes on the Use of Pin 1

When pin 1 is not to be used to refresh the chip, it should be handled in the following manner.

(1) Since pin 1 refresh is inhibited by setting the \overline{REF} input to high, the input should be set between $V_{IH\ min}$ and $V_{IH\ max}$. (The pin 1 input leakage current for $V_{IN} = 6.5V$ is guaranteed to be below 10 μ A.)

(2) When the above method is not possible, pin 1 should be left open. Since as shown in Fig. 3.33 as MOS transistor is used to connect a pull-up resistor between the input terminals and V_{CC} , the terminal will be held to a high level (V_{CC}) when left open.

However, when the input is set low in order to perform a refresh operation, a current flows from V_{CC} to the input terminal. This resistance is made a very high value (approximately 3M Ω) in order to guarantee the specified leakage current of 10 μ A maximum for $V_{IN} = 0V$.

This high resistance results in pin 1 being susceptible to the effects of external noise so that if pin 1 is to be left open, such noise should be considered carefully.

Fig. 3.33 \overline{REF} input equivalent circuit

(M5K4164S, M5K4164NS)

3.3 M5K4164S Bit Map

Introduction

To facilitate the generation of worst-case pattern checking and the optimization of test sequences, it is necessary to know the internal topology of a memory device. This section will examine the internal topology of the M5K-4164S.

Memory Array

Fig. 3.34 shows the dual in-line package as viewed from above with pin 1 to the upper right. It illustrates the memory cell layout.

The row decoder are located to the left of the memory cells while the column decoder are located parallel to the cells.

Address Decoder

Fig. 3.35 shows the address decoder. To optimize pattern layout, the decoder is arranged as shown in Fig. 3.35. For this reason, with A_0 (row) as the least significant bit and A_7 (column) as the most significant bit, sequential binary addresses will not address adjacent cells in order.

Fig. 3.34 Memory array location

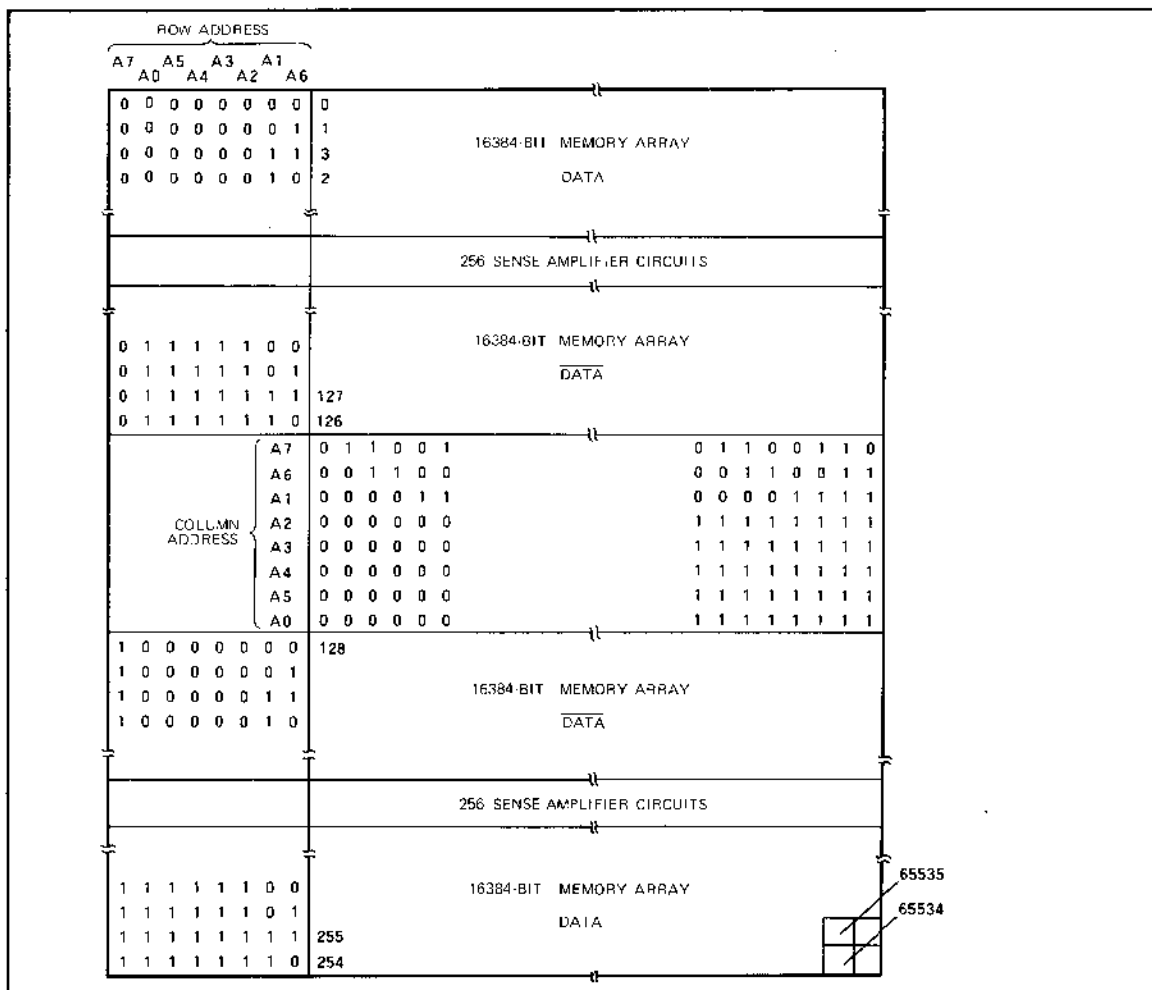

Fig. 3.35 Address decoder location

(M5K4164S, M5K4164NS)

For the arrangement of Fig. 3.35, Table 3.3 shows the addresses that will be accessed for sequentially incremented binary addresses if A_6 (row) is the least significant bit and A_0 (column) is the most significant bit.

Bit Topology

For the purposes of simplified explanation, we have assumed thus far that the memory cells are located in an orderly fashion in a matrix. For actual devices, however, techniques required to increase the density on the chip dictate that an arrangement such as shown in Fig. 3.36 is used.

For this reason, this layout must be considered carefully when designing tests which detect interference between adjacent cells.

Data Polarity

Because the sense amplifiers are located in the center of the bit lines of the M5K4164S, half of the data matrix is stored in inverted form. While this has absolutely no effect on actual operation, it must be considered if a test is to be devised which will test all cells in the charged state. This bit inversion pattern is given in Table 3.4.

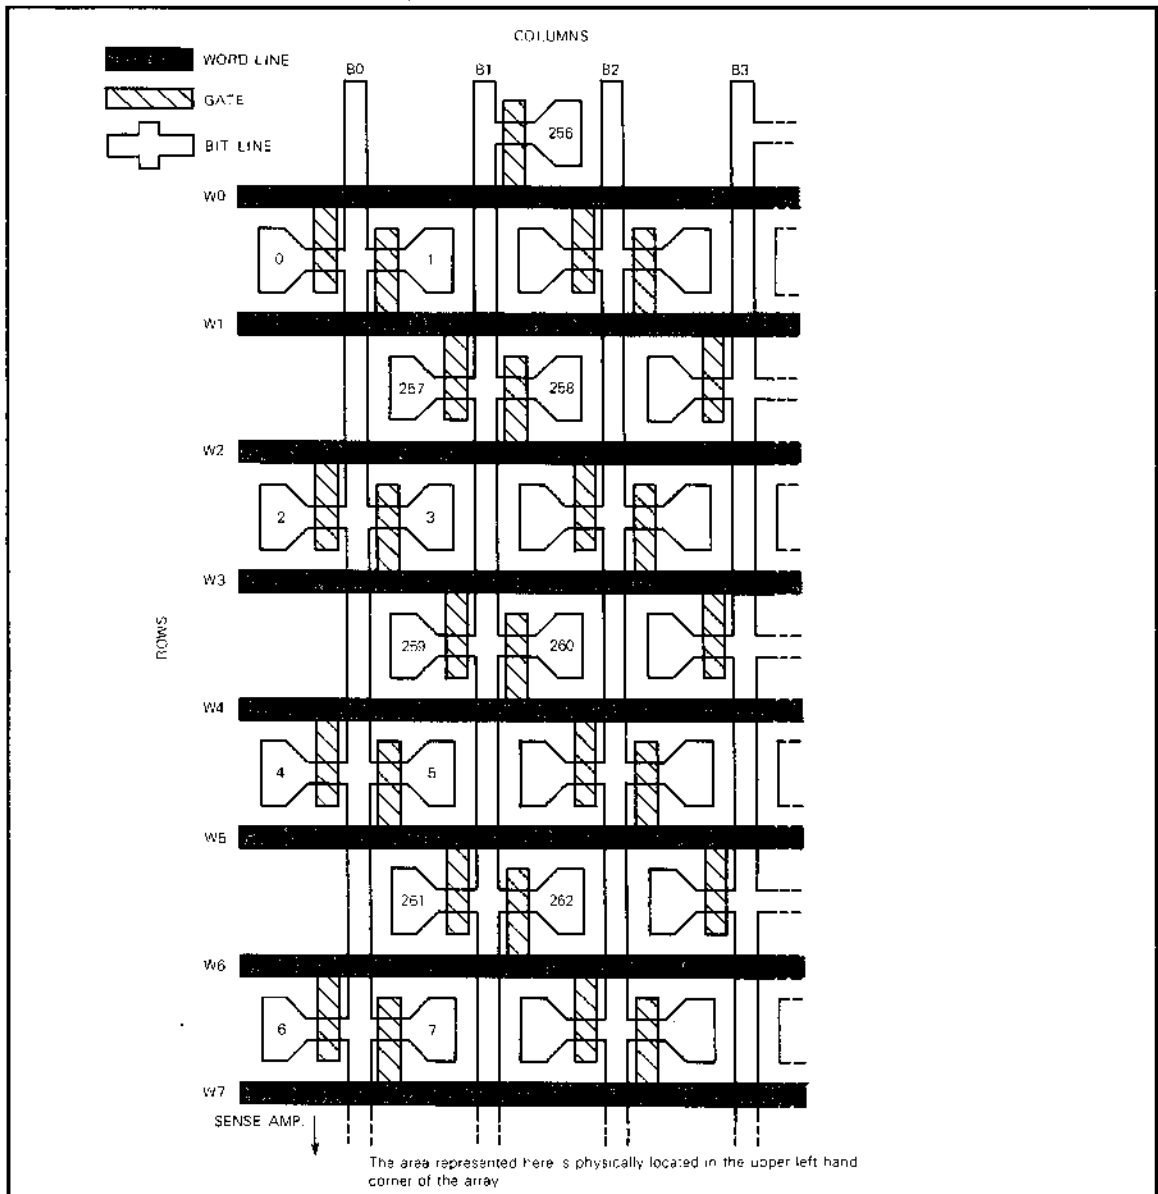

Fig. 3.36 Simplified internal bit topology

(M5K4164S, M5K4164NS)

Table 3.3 Address Coding

Cell No.	Column								Row							
	(MSB)								(LSB)

3.4 Memory System Design Considerations

New memory systems designs are making use of dynamic RAM, static RAM, EPROM and other semiconductor memory devices. All of these devices have some general design considerations in common. This application note will examine some of the delicate timing considerations involved in the design of a dynamic RAM board.

Power Distribution

Fig. 3.37 shows the current waveform of an M5K4164S dynamic RAM. Note that when $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ go low, the row or column address latch and buffer are charged, and that when $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ go high, the row or column address latch and buffer are precharged, resulting in a transient current waveform. The 60 to 80mA current pulse of approximate width 50ns and a risetime of 5~10ns represents the risetime which is observed at 50ns per division. With rise and fall times of this magnitude harmonic noise components above 10MHz are generated. It is therefore necessary when designing the board power distribution to suppress such noise and provide the device with a clean supply voltage. Decoupling capacitors should be used which are capable of charging a small loop. For a 0.1 μF capacitor value used with a 250ns cycle RAM, the spike voltage is given by the following expression.

$$v = \frac{1}{c} \int idt = \frac{80\text{mA}}{0.1\mu\text{F}} \times 50\text{ns} = 40\text{mV}$$

This yields an acceptable value of spike voltage.

It is recommended that ceramic capacitors with good high frequency characteristics are used as the decoupling capacitors in memory arrays. The decoupling capacitor is connected between the memory V_{CC} and the ground with as short a lead dressing as possible. In addition, as bulk decoupling a solid tantalum capacitor is required. This type of capacitor has a better transient response than other large value capacitors and can be used with one capacitor per 16-memory devices between V_{CC} and the ground.

The power supply traces for a memory array should be made as wide as possible and it is recommended that they be arranged in a grid. Fig. 3.39 shows an example of such an arrangement.

As another method, the use of multi-layer boards is possible, and is an effective method in simplifying power distribution.

Fig. 3.38 (a) shows the lumped constant equivalent circuit for a PC board. L_S and R_S represent the PC board inductance and resistance respectively. If we let the L_S and R_S of a 10mil wide 2-ounce copper pattern be 10nH/inch and 4m Ω /inch, then the generated spike voltage is given by the following expression.

$$L_S \cdot \frac{di}{dt} = 10\text{nH} \times \frac{80\text{mA}}{50\text{ns}} = 16\text{mV}$$

$$R_S I = 4\text{m}\Omega \times 80\text{mA} = 0.32\text{mV}$$

Since the effect of the series resistance R_S compared to that of the series inductance is very small, it may be neglected. The series resistance of L_S is frequency dependent, increasing with increasing frequencies.

To reduce the level of the spike voltage, as shown in Fig. 3.38 (a), a decoupling capacitor is used to decrease the series resistance. This is done by shortening the PC board current loop.

(M5K4164S, M5K4164NS)

Fig. 3.39 Gridded power distribution and decoupling capacitors

Logical Considerations

For memory systems with critical timing, it is necessary to consider the propagation delay to surrounding ICs. To minimize signal delay, gate selection and the use of the same IC package for related signals are effective in reducing the difference in delays between signals. To reduce the capacitive loading on drivers, it is necessary to limit the number of drivers per memory array. For $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$, 8 memory/drivers and for address 16 memories/driver are recommended.

Signal Distribution

The next most important consideration in the design of a memory system is the design of memory signal (address, data, and control signals) distribution.

For the case of the M5K4164S dynamic RAM, two types of chip enable signals exist; $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$. If these are to be driven by TTL circuits, it is very important to keep the driving TTL device as close as possible to the RAM array. This minimizes the transmission line impedance mismatch between the RAM array loaded line and the TTL driver. Another technique is the use of a damping resistor located close to the driver. The value of this resistor is selected to provide a good waveform at the RAM input, the usual values being in the range 10 to 51 Ω . This technique brings the output impedance of the driver close to the line impedance which minimizes waveform overshoot and undershoot.

To eliminate crosstalk from $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$, the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ signal lines should be kept at 90° to the traces for other signals. If this is impossible, they should be kept as far as possible from traces of other signals. In addition the address and data signal traces should be kept as short as possible.

3.5 M5K4164S Refresh Methods

Introduction

The refreshing of the M5K4164S cell matrix requires the refreshing of 128 row addresses at least every 2ms. In addition to the previously available RAS-only refresh

method, the M5K4164S provides $\overline{\text{REF}}$ (pin 1) automatic refreshing, and self-refreshing. This section will cover the application of $\overline{\text{REF}}$ refresh operations.

Automatic Refresh

Automatic refresh begins after $\overline{\text{RAS}}$ precharge ($\overline{\text{RAS}} = V_{\text{IH}}$) upon setting $\overline{\text{RAF}}$ (pin 1) to low. This method is quite similar to the $\overline{\text{RAS}}$ -only refresh with the refresh address

counter output present as a 7-bit word for automatic refreshing, the refresh counter being automatically incremented at the end of the refresh cycle. Fig. 3.40 shows the automatic refresh timing.

Fig. 3.40 Automatic Refresh Timing

(M5K4164S, M5K4164NS)

Automatic refresh has many advantages over the $\overline{\text{RAS}}$ -only refresh method generally used previously. As shown in Fig. 3.41, $\overline{\text{RAS}}$ -only refresh generally requires logic circuitry. This consists of the row-address, column-address and

refresh address multiplexer and refresh address counter. With automatic refresh, the dotted area shown in Fig. 3.41 may be eliminated.

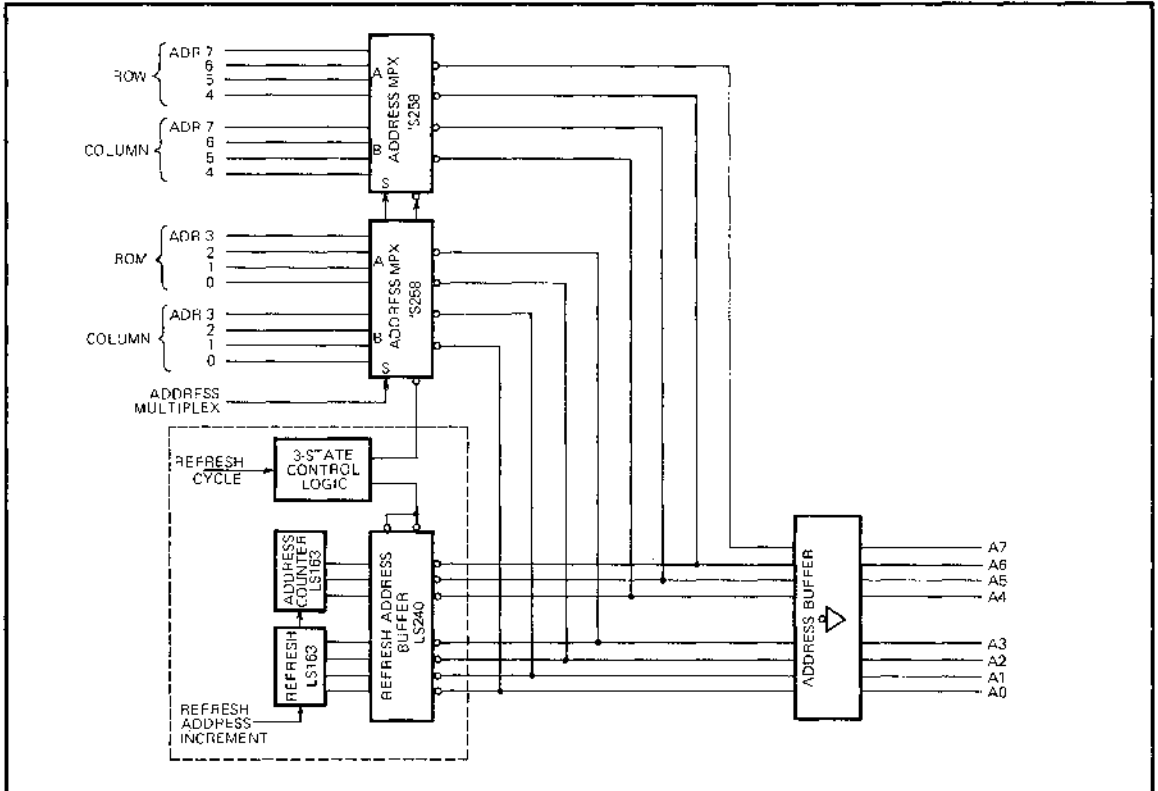

Fig. 3.41 Address multiplexer and refresh address counter

By decoding $\overline{\text{RAS}}$, one bank of a complex memory system may be selected, while for $\overline{\text{RAS}}$ -only refresh $\overline{\text{RAS}}$ is fed to all portions of the memory requiring the decoder as shown in Fig. 3.42 (a). With automatic refresh, $\overline{\text{RAS}}$ is used

during the memory cycle and $\overline{\text{REF}}$ for the refresh cycle independently so that the gate shown in Fig. 3.42 (b) can be eliminated.

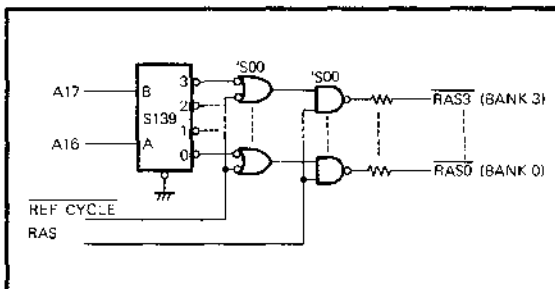

Fig. 3.42 (a) $\overline{\text{RAS}}$ decoder in $\overline{\text{RAS}}$ -only refresh

Fig. 3.42 (b) $\overline{\text{RAS}}$ decoder using REF pin

(M5K4164S, M5K4164NS)

Another feature of automatic refresh is that the timing of the refresh controller is simplified. The timing for $\overline{\text{RAS}}$ -only refresh and automatic refresh is shown in Fig. 3.43 (a) and Fig. 3.43 (b) respectively.

Fig. 3.43 (a) $\overline{\text{RAS}}$ -only refresh timing

Fig. 3.43 (b) Automatic refresh timing

For $\overline{\text{RAS}}$ -only, the controller disables the address multiplexer upon entering the memory cycle while it enables the refresh counter output. Next, after a delay time of t_1

(required because of the address buffer delay time and row address setup time $t_{su}(\text{RA-RAS})$), $\overline{\text{RAS}}$ is set to low. The refresh cycle ends at the time t_2 that $\overline{\text{RAS}}$ is precharging.

In contrast to this, the automatic refresh controller sets $\overline{\text{REF}}$ to low simultaneously with the beginning of the refresh cycle, and after the $\overline{\text{RAS}}$ precharge time t_3 , the refresh cycle ends. For this reason, there is no necessity to consider the settling time for address selection.

Self Refresh

Self refresh, similar to automatic refresh, sets $\overline{\text{REF}}$ low after $\overline{\text{RAS}}$ precharge occurs, beginning the internal refresh cycle. This method of refresh ignores all other inputs as long as $\overline{\text{RAS}}$ is high and $\overline{\text{REF}}$ is low, making use of an internal timer to automatically refresh the row addresses every 12~16 μs which enables all cells to be refreshed within 2ms. The rising edge of $\overline{\text{REF}}$ terminates the refresh operation and after one cycle ($t_d(\text{REF-RAS})$) a normal read-write cycle is entered. Fig. 5 shows the timing for the self refresh cycle. Self refresh is an extremely effective method of providing memory backup by means of a secondary power supply. As shown in Fig. 3.44, most of the required functions are implemented within the chip for the $\overline{\text{RAS}}$ -only refresh with a simplified external circuit. This results in low power consumption and a long life for the secondary power supply.

As described above, self refresh may not be used in the $\overline{\text{RAS}}$ only refresh mode. In designs using two refresh counters (internal and external) which operate independently, guaranteeing the refresh (2ms) time is difficult.

Note. Addresses, $\overline{\text{CAS}}$, $\overline{\text{O}}$ and $\overline{\text{W}}$ are don't care.

Symbol	Parameter	Alternative Symbol	M5K4164S-15		M5K4164S-20		Unit
			Min	Max	Min	Max	
$t_d(\text{RAS-REF})$	Delay time, RAS to REF	t_{RFD}	100		120		ns
$t_w(\text{REFL})$	REF low pulse width	t_{FBP}	8000	∞	8000	∞	ns

Design Example

The design example shows the increased effectiveness of $\overline{\text{REF}}$ (pin 1) refresh when the M5K4164S is used as the memory for a microprocessor. This design example illustrates the interface between the M5K4164S and the microprocessor.

When using $\overline{\text{REF}}$ for the microprocessor memory in interface, two methods are possible. One is asynchronous refresh and the other involves synchronously refreshing the memory. The former technique is not affected by the microprocessor status (i.e. reset, wait state, DMA, and cpu

clock). However, control logic is somewhat complex. While the second method makes use of simple control logic, the microprocessor must satisfy the refresh operation timing conditions.

Fig. 3.46 through 3.48 show the block diagram, schematic diagram, and timing diagram for the asynchronous refresh example. For this example, the refresh cycle counter refresh request ($\overline{\text{REFREQ}}$) starts the refresh cycle independently of the microprocessor operation. The arbiter determines whether the microprocessor (RAMREQ) or refresh cycle counter ($\overline{\text{REFREQ}}$) has access to the RAM.

A bootstrap ROM, commonly used in this type of memory system, is shown in the example. This is used to load the initial program of a RAM-based system into RAM

from disk, for system initialization. In this example, the SOD (Serial Output Data) of the M5L8085AP is used to select either the bootstrap ROM or RAM as shown in Fig. 3.49.

Fig. 3-50 and 3.51 show the schematic diagram and timing for the synchronous refresh example. In this example a Z80 microprocessor is used with synchronous refresh. As shown in Fig. 3.51, after the Z80 fetch instruction, the refresh operation is performed (T₃ and T₄ state).

In this manner refresh is performed synchronously with microprocessor operation. As mentioned previously, this type of operation involves a variety of limitations which must be considered carefully when designing such a system. (i.e. wait state, DMA, reset and CPU clock cycle)

4. STATIC RAM

4.1 M58725P Technology

M58725P Features

The M58725P is a 2K by 8-bit static RAM making use of the latest n-channel MOS technology. Beginning with the 256 bit p-channel RAM, this technology has progressed at a rate which has seen the bit capacity quadruple in 3 to 4 years and the M58725P is the latest stage of development of this technology. A high-resistivity polysilicon material is used to lower power consumption and a chip select feature is used to implement a power cut function as the major features of the new device in addition to an overall improvement in performance. Fig. 4.1 shows the progress that has been made in the field of static RAMs, using the product of per bit power consumption and access time as an index of performance. From this the significant progress that has been made with these devices in recent years becomes apparent.

Fig. 4.1 Performance improvements in MOS RAMs

Memory Cell Structure

Fig. 4.2 shows the memory cell structure which consists of six elements; four transistors and two resistors. These resistors are implemented by means of a high-resistivity polysilicon which has enabled a significant reduction of power consumption within the memory cell. The holding current in a static RAM is basically that current which is required to cancel the p-n junction leakage current, an extremely small current. However, in previous devices the implementation of high resistances has been difficult, resulting in unnecessarily large power consumption. The M58725P using a two-layer polysilicon process has implemented this resistance by making the resistance of the second layer high (approximately $100M\Omega$), thereby also resulting in a reduction in cell area.

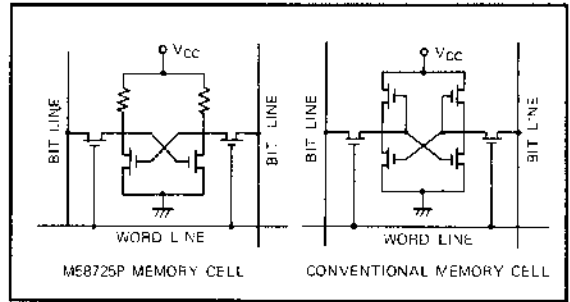

Fig. 4.2 Memory cell structures

Power Cutting with the Chip Select Signal

In order to take full advantage of the inherently low power memory cells of the M58725P, a chip select signal (\bar{S}) is used to provide a power cutting function. In the standby mode the power consumption to the peripheral circuitry is almost completely eliminated, leaving a very small part of the consumption of the peripheral circuit and the inherently low consumption of the memory cells. As shown in Fig. 4.3, when \bar{S} is made high the power consumption is 1/10 of the normal level. This feature is particularly effective in lowering overall consumption in systems which use several RAM devices.

When the \bar{S} signal changes levels, the circuit current changes rapidly so that decoupling capacitors in the power supply line are recommended to prevent noise generation.

Fig. 4.3 Power cutting feature

(M58725P, M5L2114LP)

\overline{OE} Signal

The output enable signal \overline{OE} controls the output for use on two-way buses to prevent several devices from bus contention. For writing, this signal is made high, thereby disabling the output. The output is enabled by setting it low as for reading operations. When using the M58725P

with the 8085, 8086 or similar microprocessors, the CPU \overline{RD} signal can be connected to the \overline{OE} input to effectively prevent bus contention. Another method does not rely on use of the \overline{OE} signal. Refer to the section on writing operations for details.

FUNCTIONAL DESCRIPTION

Read Operations

Fig. 4.4 shows the timing relationships for read operations. The section at (a) illustrates the access time from address selection. Since the M58725P is a completely asynchronous device, reading data at the DQ outputs requires only that the address be selected with the \overline{OE} input low. If the setting of \overline{OE} is late, the access time will depend on the timing of the falling edge of the \overline{OE} signal. If it is sufficiently fast, the access time will be determined by the time $t_a(A)$.

Fig. 4.4 (b) illustrates the access time from the operation of chip select. With previously available RAMs without the power cutting feature, the chip select access time $t_a(S)$ was quite a bit faster than the address access time $t_a(A)$ in most cases. With the M58725P however, these two access times are the same careful consideration must be given to timing relationships when laying out PC boards.

Fig. 4.4 Read cycle timing

(M58725P, M5L2114LP)

Write Operations

Fig. 4.5 illustrates the timing relationships for write operations. The data at the DQ inputs will be written into memory upon the rising edge of either \bar{W} or \bar{S} but this data should be kept stable in the period between $t_{su}(D)$ and $t_h(D)$. To prevent bus contention before the data to be written is applied, the input \bar{OE} should be set to high. If the \bar{OE} signal is not used, the falling edge of the \bar{W} signal must

be made simultaneous with or earlier than the falling edge of the \bar{S} signal. This will keep the DQ pins in the high-impedance state and prevent bus contention. For use with the 8085, 8086 or similar processors, the \bar{S} signal can be gated with the \bar{WR} and \bar{RD} signals to achieve this effect. This is required to prevent data from being written into the address of the cycle previous to $t_{su}(A)$ or following t_{wr} .

Fig. 4.5 Write cycle timing

4.2 Static RAM Application

Mainframe memories tend to be large in bit capacity of various word widths. Microprocessor memories, in contrast, are typically smaller in size with a fixed word width of 8 or 16 bits. Static RAM, which do not require special refresh or

timing circuitry, are suitable for microprocessor application which demands low cost and ease of use in a 4- or 8-bit memory organization.

M5L2114L

When using a static RAM like the M5L2114 which has common input/output and no \overline{OE} (output Enable), the problem of bus contention should be considered. Fig. 4.6 shows the decoding technique for the M5L2114L.

Controlling the chip select with the READ or WRITE command prevents the M5L2114L from driving against the transceiver prior to the command. The limitations of this method are access time to read or write and a limitation of \overline{CS} to write setup and hold time. The timing diagram is shown in Fig. 4.7.

Controlling the chip select with the READ or WRITE

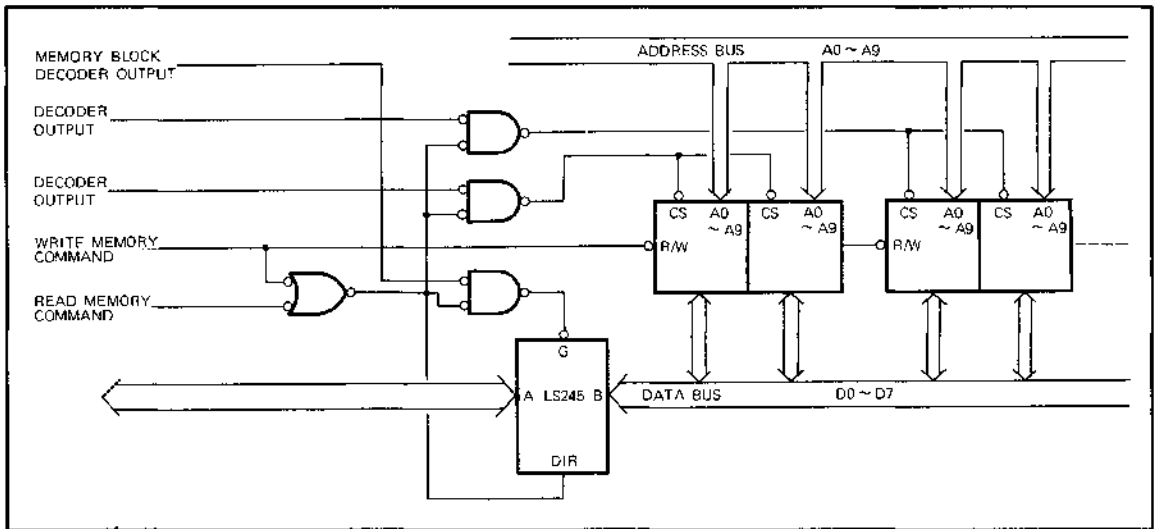

Fig. 4.6 M5L2114L decoding example

Fig. 4.7 M5L2114L timing diagram

(M58725P, M5L2114LP)

M58725

The 2K x 8 bit M58725 is more suitable for microprocessor applications, because the pin configuration of the M58725 is similar to that of the M5L2716K EPROM and the M58725 has byte memory organization. Fig. 4.8 shows an example of the M58725 interfaced to an 8085A microprocessor. RAM (M58725) or EPROM (M5L2716K) can be selected respectively by eight jumper switches. The interchangeability makes the system flexible and is convenient at the development stage of a microprocessor system which needs to use RAM.

I/O loading

There is capacitive loading at each memory's I/O pins and signal path line of the print current board. If many memories are used on a common bus, this loading prevents the guaranteeing of AC characteristics. For example, the M5L2114L has drive capacity of 2.1mA under capacitive loading of 100pF to guarantee the specified AC characteristics. A separate bus technique such as shown in Fig. 4.6 should be used in these cases.

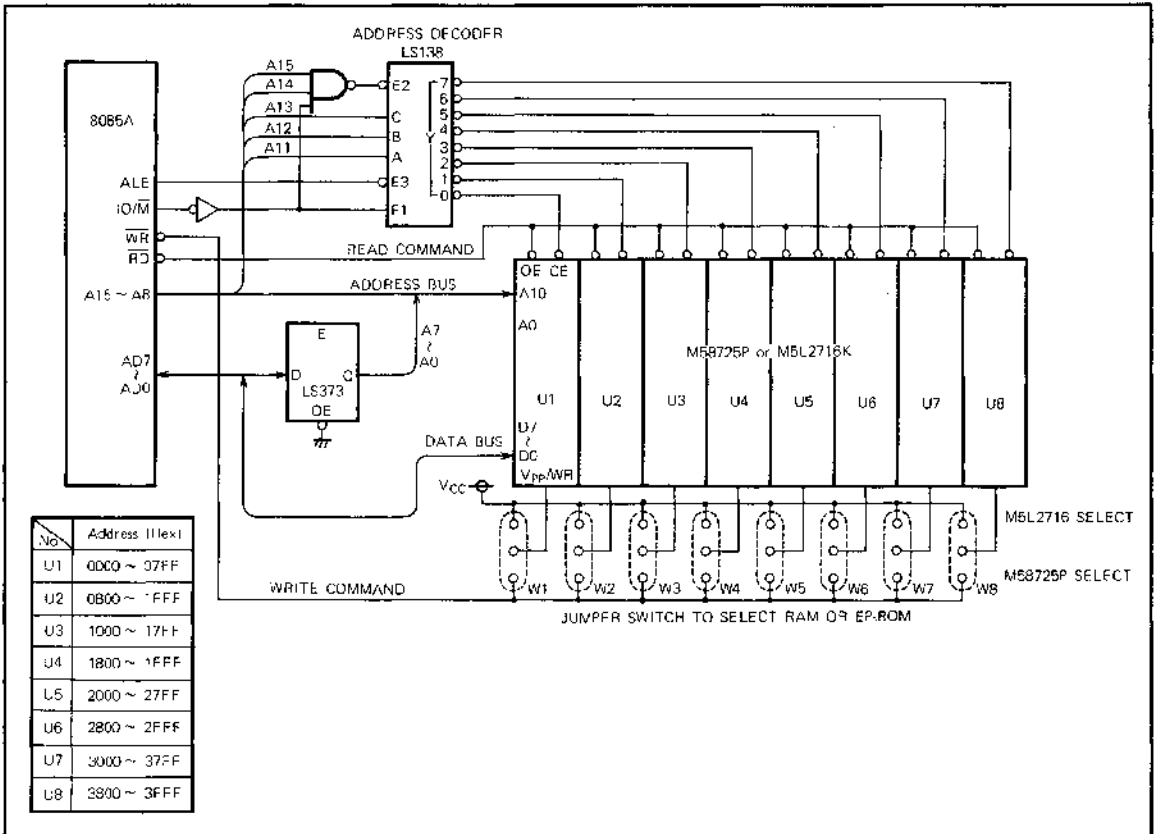

Fig. 4.8 Mixed EPROM and RAM application

5. CMOS STATIC RAM

5.1 M58981P Technology

Introduction

Since the low power consumption of CMOS RAM can be utilized to implement a battery backed-up non-volatile memory, the demand for these devices is increasing for use in equipment such as electronic cash registers and point-of-sales equipment. The M58981P was designed as a 4K-bit CMOS RAM to fill this demand. It utilizes silicon gate CMOS technology to achieve high speed and high density. The M58981P is an asynchronous CMOS RAM configured in 1,024-word by 4-bit words. It is pin-compatible with the Mitsubishi Electric M5L2114LP n-channel 4K static RAM and the Intel 2114. An advanced micro-pattern process has enabled the formation of 26,000 devices in an area of 20mm², packaged in an 18-pin DIL plastic package.

Memory Cell

The memory cell used in the M58981P is shown in Fig. 5.1. It consists of a CMOS circuit (with n-channel transfer gate) of 6 transistors.

Circuit Configuration and Operation

Fig. 5.2 shows the block diagram of the M58981P, with the timing diagram shown in Fig. 5.3.

(1) Write Operations

The address signals $A_0 \sim A_9$ select the address and when the R/W signal goes low, the I/O data at that time is written into memory. The write operation is performed during the overlap time when \overline{CS} and R/W are low. When the I/O pin is in the output mode, care should be taken to prevent the data output from causing bus contention.

(2) Read Operations

The address is specified by the $A_0 \sim A_9$ signals. When the R/W signal goes high, the data from the specified address appears at the I/O pin.

(3) \overline{CS} Signal

The chip select signal (\overline{CS}) selects the chip when set to low, and removes the chip from the bus when set to high. The output is floating enabling wired-OR connection with other chips. When the \overline{CS} signal is high, no current flows in the input buffer (refer to block diagram). All word lines become low, and all memory cells are "unselected", the DC current flowing between V_{CC} and ground falling to a very low leakage current level. This is the standby condition, one of the major features of a CMOS RAM.

(4) Power Down Operation

Data hold can be accomplished with V_{CC} to 2V or greater. \overline{CS} is made common with V_{CC} for (2V~2.2V power down) or greater than 2.2V (power down greater than 2.2V) to hold memory contents.

5.2 CMOS STATIC RAM APPLICATIONS

INTRODUCTION

Mitsubishi M5L 5101LP and M58981P are static RAMs that are fabricated with a CMOS technology. The M5L 5101LP is organized as 256 words of 4 bits, and the M58981P is organized as 1024 words of 4 bits. They are fully TTL-compatible, and use only a single 5V supply voltage V_{CC} .

The purpose of this application note is to describe the various circuit techniques for battery-supported non-volatile memory systems. Electrical characteristics for the two RAMs can be found on the previous pages.

NON-VOLATILE MEMORY SYSTEM

We can relatively easily design a large non-volatile memory system with little additional interface logic by using CMOS RAMs. The block diagram of a basic computer system that uses CMOS RAMs is shown in Fig. 5.5, and the power supply on-off timing of the system are shown in Fig. 5.6. It is usually necessary to have advanced warning that AC power has been lost. This warning signal produced by the power-fail-detect circuit interrupts the processor, which stores the volatile data in the non-volatile area (CMOS RAMs) before the system's DC source drops. And after the RAMs have been protected, their V_{CC} power source is replaced by V_{BAT} , as shown in Fig. 5.6.

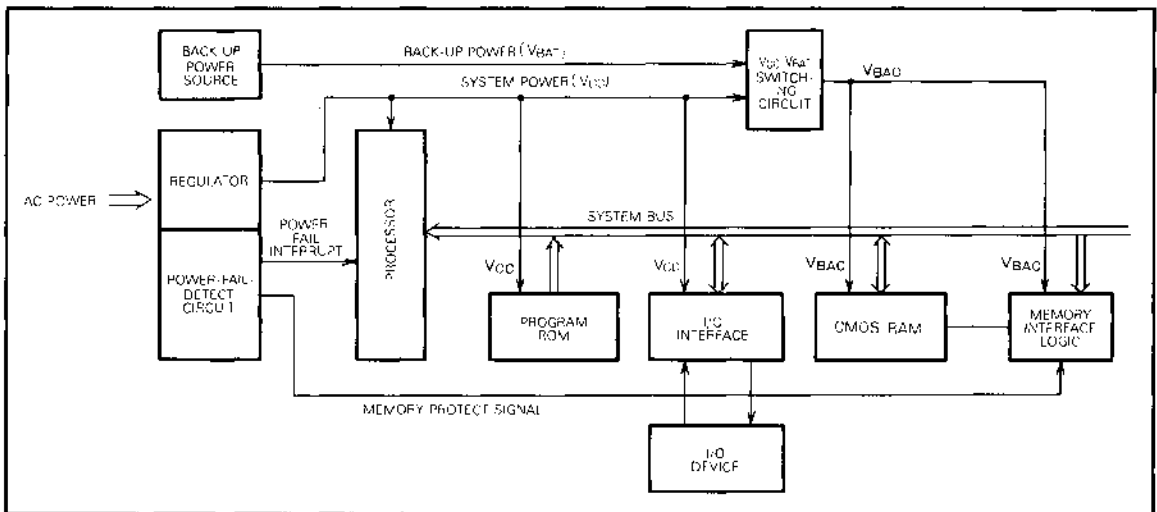

Fig. 5.5 Non-volatile memory system

Fig. 5.6 Power on-off timing

(M58981P, M5L5101LP-1)

EXAMPLE OF CMOS NON-VOLATILE MEMORY SYSTEM

Power-Failure Detection

The power-fail-detect circuit watches a separate power supply point to provide an advanced warning of power failure. As described before, this warning signal (power fail) can interrupt the processor or merely protect the CMOS RAMs.

Fig. 5.7 is a simplified diagram of the power-fail-detect circuit. This shows that the power failure is detected from the secondary transformer output, which is not regulated. The Zener-diode voltage and RC time constant should be well selected to prevent AC power failure from shutting down the memory system.

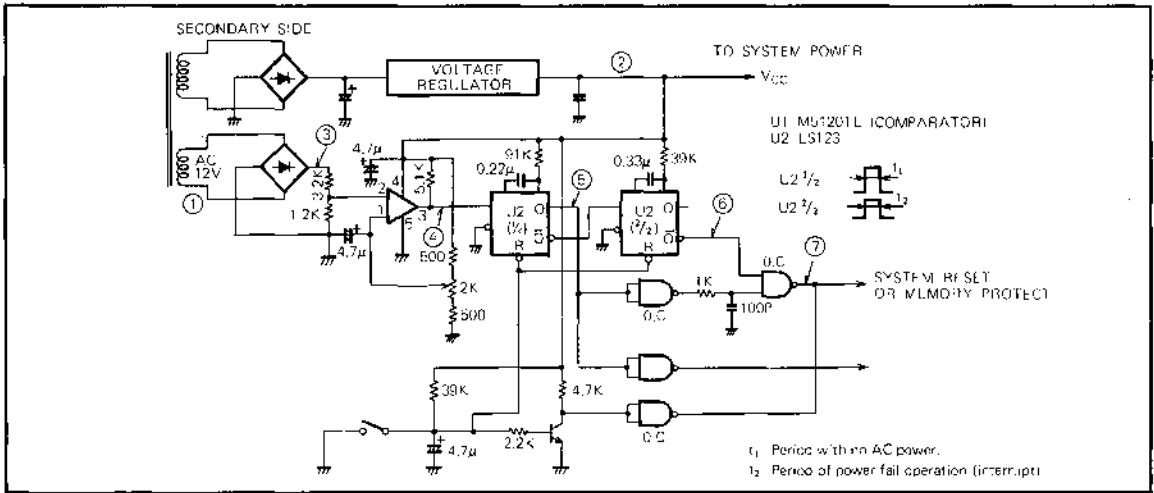

Fig. 5.7 Power-fail-detect circuit

Power-Switching Circuit

The power-switching circuit replaces the main source V_{CC} by the back-up power source V_{BAT} when V_{CC} drops, and replaces the V_{BAT} by the V_{CC} when the V_{CC} voltage rises enough to enable normal operation.

Two types of power-switching circuit are shown in Fig. 5.8 and Fig. 5.9. The diode-coupled circuit in Fig. 5.8 requires the main DC supply V_{CC} to be above the required V_{BAC} voltage by the amount of drop through the diode (about 0.6~0.7V). Fig. 5.9 shows a transistor-coupled circuit, which has better performance than the circuit in Fig. 4. In this case it is recommended to use a transistor with low collector-base saturation for Q1.

Fig. 5.8 Diode-coupled switching circuit

Fig. 5.9 Transistor-coupled switching circuit

(M58981P, M5L5101LP-1)

TYPICAL APPLICATION CIRCUIT

An Example of M5L5101LP-1 Application

An example of a 1K-byte non-volatile M5L5101LP-1 memory system is shown in Fig. 5.10. In this case, the memory-protect signal is detected from the voltage of power source V_{CC} . But it is better to watch the unregulated voltage (see Fig. 5.7) to produce the memory-protect signal that protects RAMs at the time when V_{CC} is dropping or rising as shown in Fig. 5.6. The CE2 pin is used for decoding the RAM array. When the RAMs are not selected (i.e. CE2 = low-level), they enter a stand-by mode, and the power supply current is extremely low.

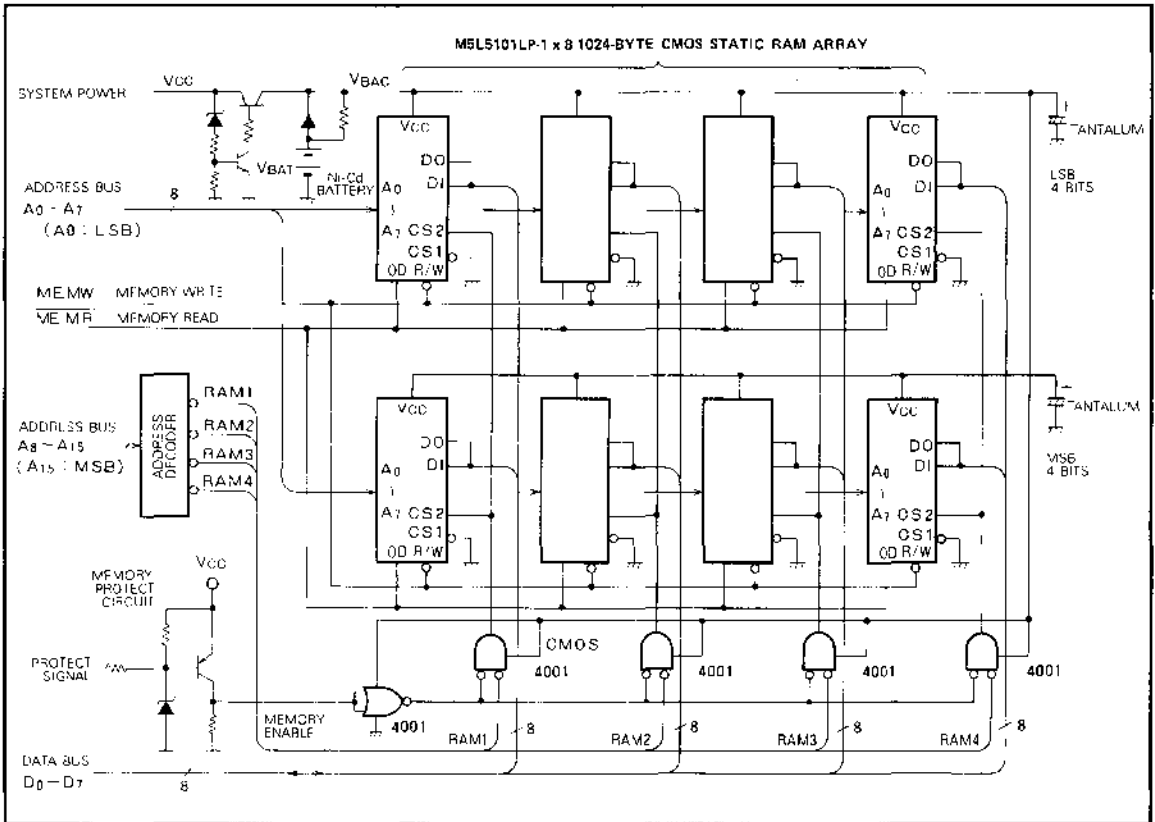

Fig. 5.10 Example of M5L5101LP

(M58981P, M5L5101LP-1)

An Example of M58981P

The M58981P is a CMOS RAM which is fully pin compatible with M5L2114LP is organized as 1024 words of 4 bits. The M58981P has two control inputs, \overline{CS} and R/W. The \overline{CS} can control normal memory operation and stand-by operation. When the RAM is in the stand-by mode (i.e. $\overline{CS} \geq 2.2V$), the power supply current is extremely low.

Fig. 5.11 shows the memory signal timings at the time when AC power turns on and off. An example of 4K-byte non-volatile memory system using M58981P is shown in Fig. 5.12.

Fig. 5.11 Power on-off timing (M58981P)

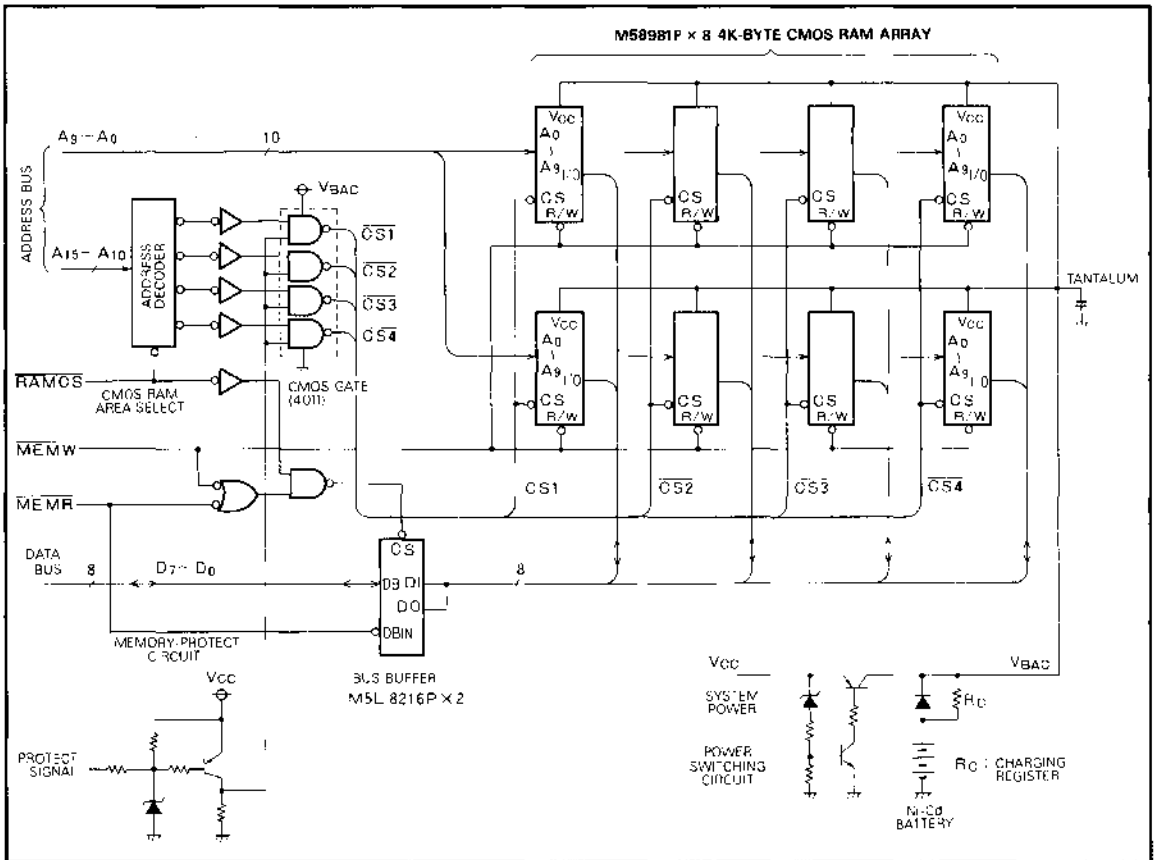

Fig. 5.12 Example of M58981P

Other Recommendations

1. Nickel-cadmium batteries are available for the memory back-up power source because of its rechargeable operation and wide variety of capacities, sizes and styles. For details, see related articles.
2. In order to decrease the DC power-source impedance, decoupling capacitors whose leak currents are small should be used. It is also necessary to use 0.01~0.1 μ F monolithic-type capacitors and 2~5 μ F tantalum types effectively.
3. When CMOS gates are used for decoding logic as shown in Fig. 5.10 and Fig. 5.12, it should be carefully ascertained that the propagation time of CMOS gates does not exceed the access time of memory, and also that the stand-by voltage of the gates does not drop below 3V. (It is possible to reduce the propagation time of CMOS gate using high-speed CMOS gate version TC40HXXX series.)

6. EPROM

6.1 EPROM Technology

INTRODUCTION

With their ability to be electrically programmed and erased with ultraviolet light, EPROM (Erasable and Programmable Read Only Memory) devices have achieved high popularity for their ease-of-use and are retaining their position as the target for memory development.

Although the EPROM was originally developed for use as a microprocessor system debugging ROM, the device has undergone significant improvements in density, reliability, and basic process technology as well as cost per bit which have extended its usefulness beyond microprocessors into such equipment as cash registers, point-of-sale equipment, household appliances, entertainment equipment, and a variety of other fields. Since the introduction by Mitsubishi Electric of a p-channel 2K-bit EPROM, the development of n-channel devices has enabled remarkable improvements in access time, and density in the form of an 8K-bit device. The development of devices operable from a single power supply greatly improved ease-of-use of the 16K- and 32K-bit devices which were to follow. This section will briefly outline the progress made in EPROM technology including a description of circuit configuration and notes on applications.

The Structure and Basic Operation of a Memory Transistor

As shown in Fig. 6.1, increasing EPROM capacity has been accompanied by changes in the memory transistor structure. The 2K-bit device made use of a P-channel MOS transistor to form an insulated single-layer polysilicon floating gate. In contrast to this, devices of 8K-bit capacity and greater make use of n-channel transistors and two-layer gate structure with a control gate to which a voltage may be applied placed over the floating gate. A capacitance between the control gate and the floating gate form an acceleration field for electron injection to the floating gate. Programming is performed in the following manner. For programming operations a high voltage is applied to the drain and control gate. By virtue of the control gate, capacitance between control gate and floating gate a channel is formed between the source and drain through which a current flows. As a result, for high drain voltages current induced breakdown occurs. The hot-electrons produced as a result of this breakdown phenomena exceed the high energy barrier and are injected into the floating gate. By imparting a voltage to these injected electrons the control gate can have higher threshold voltage than before injection (refer to Fig. 6.2), and the read voltage may be applied to the control gate while maintaining an open circuit. This ends the write operation. This applies to the memory transistors used in presently available EPROM devices of 8K-bit capacity and over. Fig. 6.3 shows the programming characteristics (dependency of the threshold value on the write pulse width) for 16K- and 32K-bit memory transistors.

The injected charge is located on the floating gate which is surrounded by a 1,000Å thick silicon oxide layer of good insulating characteristics, and is therefore retained for a long period. It is the retention of this charge which holds the written data. A significant feature of two-layer gate structure is the associated increase in density. As shown in Fig. 6.1, whereas in the single-layer gate an additional row selection transistor is required, the two-layer memory transistor eliminates this necessity by having the control gate serve two functions.

Fig. 6.1 Memory transistor construction

Fig. 6.2 Variation in memory transistor threshold voltage (V_{G0} : Read gate voltage, both vertical and horizontal scales are arbitrary)

(M5L2716K, M5L2732K, M5L2764K)

The introduction of 8K- and 16K-bit devices and greater was accompanied by improvements of control gate structure. As shown in Fig. 6.1, whereas for the 8K-bit device the side of the floating gate is completely covered by the control gate, this is not true of devices of 16K-bit capacity and greater. It should be noted that while significant improvements in overall capacity has been made, chip size remains essentially unchanged, the 16K-bit chip size being merely 8.2% greater than that for the 8K-bit device.

Erasing is done by exposing the device to ultraviolet light. The electrons on the floating gate receive the ultraviolet energy, pass through the oxide layer and escape. The transmittivity of ultraviolet radiation from a low pressure mercury lamp through polysilicon is low compared to silicon oxide. For this reason, the ultraviolet energy reaching the floating gate of 16K-bit and greater memory devices using transistors without polysilicon sides is larger than the 8K-bit structure. This results in shorter erase times for 16K-bit devices and over. Fig. 6.4 illustrates the change in threshold value by exposure of ultraviolet energy.

Fig. 6.3 Dependency of V_{TH} on write pulse width (16K-bit and 32K-bit)

Fig. 6.4 Variation in V_{TH} with erasure time

Fig. 6.5 EPROM Block diagram

EPROM Circuit Configuration and Characteristics
Circuit Configuration

Fig. 6.5 shows the block diagram of an ultraviolet light erasable EPROM. Currently available devices are configured in 8-bit words with the memory cells arranged in eight blocks. Input and output is performed in parallel by means of the signal lines $D_0 \sim D_7$ connected to these eight blocks. The address signals are divided into column decoder inputs and row decoder inputs. For a 32K-bit EPROM, the $A_0 \sim A_3$ (four lines) address signals are input to the column decoder while the $A_4 \sim A_{11}$ (eight lines) address signals are input to the row decoder, the memory being arranged as a matrix of 2^4 (=16) columns by 2^8 (=256) rows.

After decoding, the column signals are input to the column selection transistor gate which is connected to the memory cell drain. Finally, the decoder row inputs are connected to the memory control gates. Sense amplifiers and data input/output buffers used in read and program operations are connected to the drains (data lines) of the memory cells controlled by the column selector transistors. Almost all of the chip area is taken up by the memory cells, address circuits, decoders, and data circuits, the remaining area being allotted to the important control circuits.

These control circuits consist of the chip enable and output enable circuits. The former controls the power down operation or programming operations. The latter circuit controls the enabling or disabling of the output signal by means of the OE signal. 16K-bit devices and over are provided with these two select/unselect control circuits. The two line control method is very effective for OR-connecting of multiple devices. If only one signal were allowed to control chip select and unselect, cases could arise where one chip is enabled for output before the previous chip goes into the floating state.

(M5L2716K, M5L2732K, M5L2764K)

As shown in Fig. 6.6, this results in excessive current flowing and the generation of power supply noise. In addition, data on the bus is unstable before and after address changes. This condition is called "the bus contention problem" and can be eliminated by using the \overline{CE} as the chip enable and \overline{OE} as the output enable signal in a two-line control mode.

EPROM Operation, Characteristics, and Application Notes.

The basic operations possible with an EPROM are programming, read, and erase. These operations will be discussed with respect to 16K- and 32K-bit devices along with some precautions for use. Table 1 summarizes a comparison of the characteristics of EPROM devices currently available.

(1) Programming Operations

The normal state of all cells for an EPROM device when shipped or after erasure is "1", programming operations change the memory cell contents to 0. Programming operations are performed in groups of 8 bits (one word). After applying the programming voltage to the programming pin and selecting the program mode, the address data is set up. Next, a programming pulse of the required width is input. The active state of this pulse depends on the device (for instance, for 16K-bit devices the pulse is active high while for 32K-bit devices it is active low), so that care should be taken when generating this pulse. Although it is often thought that the higher the programming voltage and the wider the programming pulse, the more effective the programming operation will be, the device characteristics dictate that the best programming will be achieved by setting these values to the central specification values. In particular, the maximum allowable voltage for programming that may be applied to the Vpp pin is 26V. Care must be taken that the Vpp supply doesn't overshoot the 26-volt maximum specification. Programming for both 16K- and 32K-bit devices can be performed in any arbitrary order, further simplifying the programming operation.

Table 6.1 Comparison of Available EPROM Devices

MEMORY CAPACITY (BITS)	2K (256×8)	3K (1024×8)	16K (2048×8)	32K (4096×8)
TYPE	M5L1702AS	M5L2708K	M5L2716K	M5L2732K
CHANNEL TYPE	p	n	n	n
CHIP AREA	14.2mm ²	17.8mm ²	19.3mm ²	22.5mm ²
ADDRESS ACCESS TIME (MAX)	1000ns	450ns	450ns	450ns
POWER DISSIPATION (MAX)	600mW	800mW	525mW	787mW
POWER DISSIPATION PER BIT	0.3mW	0.1mW	0.03mW	0.02mW
SUPPLY VOLTAGES	+5, -9V	+5, -5, +12V	+5V	+5V

Fig. 6.7 Read timing diagram

(2) Read Operation

The read mode is enabled by lowering the program voltage and using the chip enable signal to select the chip, and the output control signal to enable the output of the memory contents at the selected address. The chip enable signal serves also as the power down signal, enabling an extreme limitation on power consumption for the non-selected periods. Access time is specified in terms of chip enable, address, and output enable access times, the power down feature making the chip enable access time generally the longest. Operating conditions and output timing should be carefully considered as high temperatures and excessive output loads have an adverse affect on access time. Fig. 6.7 shows the read timing for 16K-bit and 32K-bit devices with Fig. 6.8 and Fig. 6.9 giving the chip enable access time dependency on temperature and load capacitance.

Fig. 6.8 2716 Chip select access time temperature characteristics example

Fig. 6.9 2716 Chip select access time load capacitance dependency

(3) Erasure

Erasure is performed by exposing the chip to ultraviolet light. Fig. 6.4 shows the change in memory transistor threshold value with relationship to ultraviolet radiation. The erasure time should be selected to allow for variations in the memory transistor characteristics. Fig. 6.10 shows the relationship between the ultraviolet radiation time and the number of bits erased. Verification of erasure by means of a PROM should not be assumed to indicate that the EPROM is sufficiently erased. While the required erasure time depends upon factors such as the type and condition of the lamp used and the distance to the device being erased, the actual erasure procedure should be continued for a period of five times the time required to erase all cells as verified by a PROM programmer. Generally, for 16K- and 32K-bit EPROMs, the erasure time for a GL-10 lamp 2.5cm away from the device is between 15 and 20 minutes.

The erasure characteristics for 8K-bit EPROMs differs from those for 16K-bit and greater capacity for structural reasons, with the differences extending to the degree of influence of sunlight and fluorescent lighting on the inadvertent erasure of data. To prevent such long term ambient radiation from affecting electrical characteristics, the use of a seal to cut out such radiation for normal use is required.

Fig. 6.10 Erasure characteristics example for 2716 and 2732

(M5L2716K, M5L2732K, M5L2764K)

6.2 APPLICATION OF EPROMS

EPROM control functions

EPROM control functions are provided to simplify interface and allow full utilization of performance. A new generation of dual-control function EPROMs has become popular which has both a chip enable (\overline{CE}) and an output enable (\overline{OE}) control input.

\overline{CE} (Chip Enable, active low)

The falling edge of \overline{CE} activates the address input buffers and latches the address in preparation for the address decoders and the sense amplifiers to perform their function. This acts also as a power control function, allowing the device to enter a low-power standby mode when the \overline{CE} input is disabled.

\overline{OE} (Output Enable, active low)

\overline{OE} controls the device's output buffer, and is used to avoid bus contention since the device's output can be turned on and off directly by the processor. The \overline{CE} and \overline{OE} control functions are ANDed inside the device. This means that only the simultaneous application of \overline{CE} and \overline{OE} will activate the output of the device. (When either of \overline{CE} or \overline{OE}

is not active, the output buffer of the device goes into the high-impedence state.)

Microprocessor interface

As described above, EPROMs can be interfaced easily to microprocessors using the \overline{CE} and \overline{OE} functions. A typical example is shown in Fig. 6.11. The address from the microprocessor is decoded by the bipolar PROM which generates the primary decoded signal \overline{CE} . Next, read memory command from the microprocessor enables \overline{OE} . This decoding method makes possible a substantial power saving.

EPROM package compatibility and design technique

As the density of EPROMs increase, more address pins will be needed for higher density devices. But the EPROM family has similar pin configurations maintain which keeps the compatibility with each memory size devices. The pinouts of the family are shown in Fig. 6.12 which have different signals at the dotted pinouts only. It may seem as though the 28-pin package is not compatible with the 24-pin devices, but the lower 24 pins are indential to the 24-pin package of 2716 or 2732 as shown in Fig. 6.12.

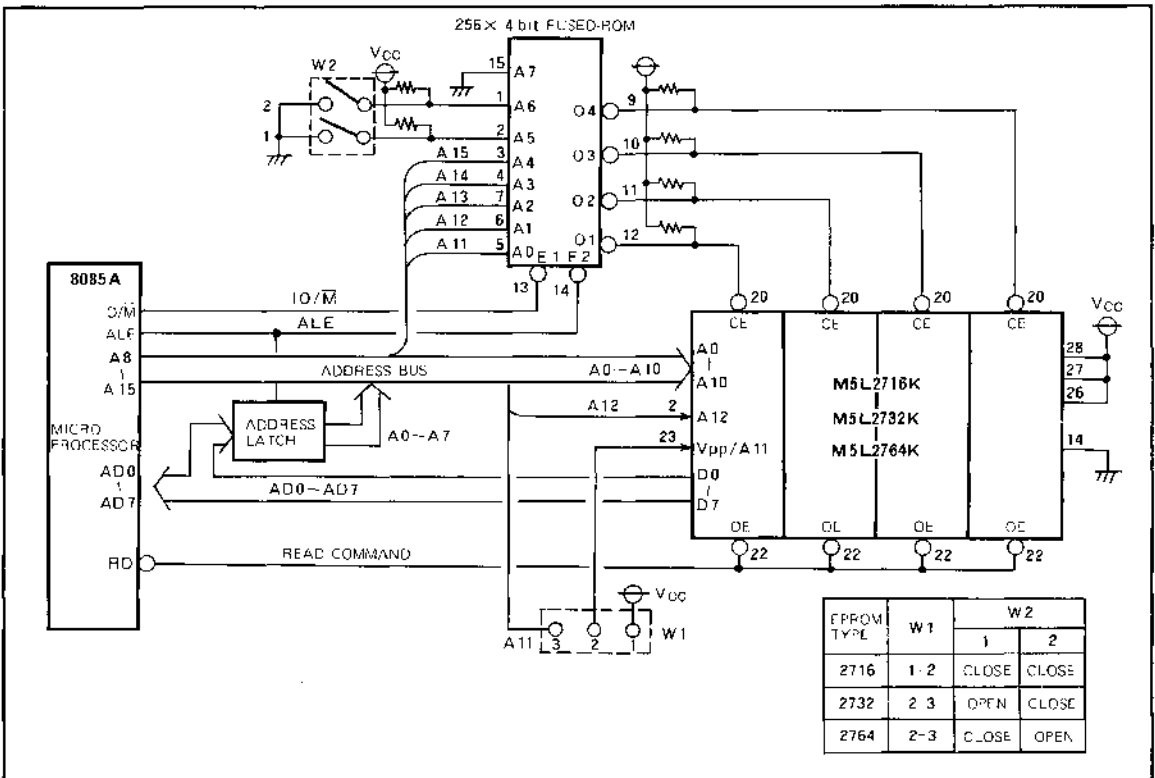

Fig. 6.11 Microprocessor-EPROM interface example

(M5L2716K, M5L2732K, M5L2764K)

The pinouts of the EPROM family enable the memory design to support 2K-, 4K-, and 8K-byte EPROMs, which require some techniques of address decoding and print circuit board layout. Fig. 6.11 shows how the EPROM family may be connected to the very popular M5L8085A microprocessor. The high-order microprocessor address

bits are fed to a 256x4 bipolar PROM for address spatial decoding. The PROM allows the address space to be re-defined at any time so that various EPROMs can be used. The jumpers W1 and W2 are used to define the type of EPROM according to the table in Fig. 6.11. The address map of the PROM is shown in Table 6.2.

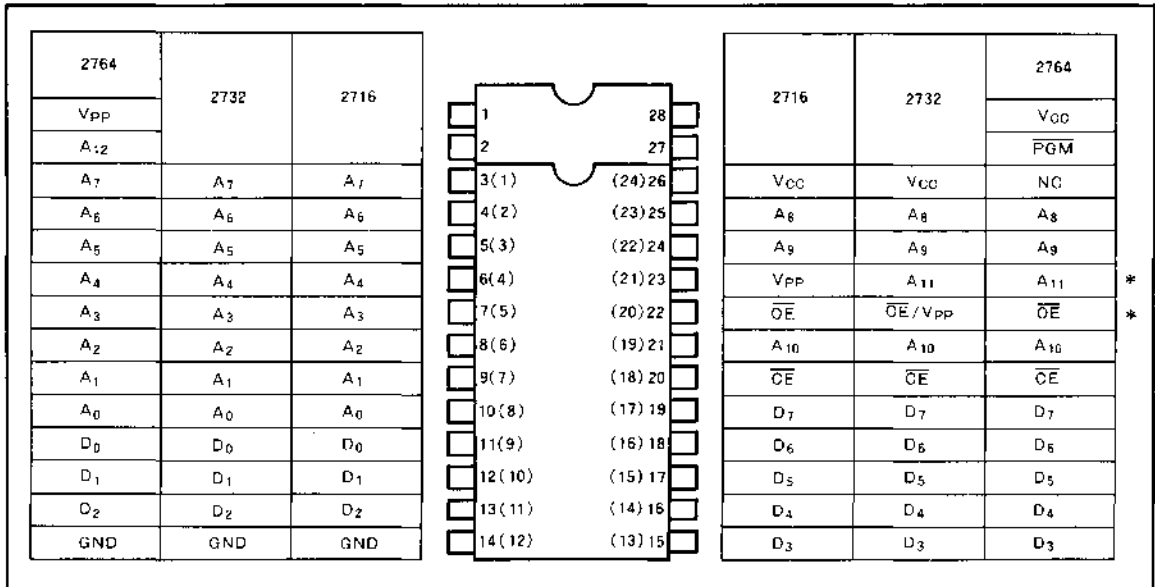

Fig. 6.12 EPROM Family pinouts

Table 6.2 PROM Address Map

Input signal Decoder address	W2-2, W2-1			Microprocessor's address					Decoder outputs			
	GND	W2-2	W2-1	A ₁₅	A ₁₄	A ₁₃	A ₁₂	A ₁₁	O ₁	O ₂	O ₃	O ₄

Functional description of M5L8041A-006P

General

M5L8041A-006P is a slave computer LSI which is designed for EPROM writer control using a mask-programmed M5L8041A-XXXXP. The operation mode of the PRPG is defined by the master microprocessor. So it is programmed by the system's software as an I/O peripheral.

Command description

There are 7 commands provided for programming the PRPG. These commands are sent on the data bus with the signal \overline{CS} at low and the signal A_0 at high and are stored in the PRPG at the rising edge of the signal \overline{WR} .

The summary of PRPG's commands and status is shown in Table 6.3.

PRPG Timing and interfacing

PRPG's operation timing are triggered by the commands are shown Table 6.3. There are two operation modes, 2716 mode and 2732 mode, whose timing are shown in Fig. 6.13 and Fig. 6.14.

Application for EPROM writer

Introduction

M5L8041A-006P is one of the applications for EPROM writer controller which can interface to microprocessors (e.g. 8080A, 8085A, 8086). EPROM writer design is simplified by using M5L8041A-006P.

Features of the M5L8041A-006P;

- EPROM write controll for the 2716 or 2732
- Fully compatible with Mitsubishi microprocessors
- Reduces the master microprocessor's program for EPROM writing.

PRPG interface and timing

An example of PRPG interfacing is shown in Fig. 6.15. Using the PRPG, the design of the EPROM writer is simplified. M5L8243P is used for the port expander of PRPG.

PRPG's operational timing is managed by the commands shown in Table. 6.3. There are two operation modes (i.e., 2716 and 2732 mode) whose timing is shown in Fig. 6.13 and Fig. 6.14 respectively. If the mode set command is not equal to the hardware switch to select 2716 or 2732 in the Fig. 6.15, the mode will not be set and the FAIL LED will light.

Design example of EPROM/RAM board

Fig. 6.16 presents the design example of EPROM/RAM board which is fully compatible with the proposed IE³-P796 bus standard. The M5L2716K, M5L2732K or M5L2764K can be used in this board, and also 2Kx8 bit of RAM (M58725 P) can be mixed with M5L2716K.

ERROR DETECTING AND CORRECTING

7. Error Detecting and Correcting

1. Introduction

The reliability of semiconductor memory devices is extremely high, so that for normal operation performance can be guaranteed without the use of special correcting circuits. However, for applications requiring even greater reliability, or in which the large number of ICs used in the system causes a reduction of the overall MTBF, some form of data error correction is required. This section will examine errors in memory devices and techniques for detecting and correcting them.

2. Error Checking Concept and the Redundancy Code

A code which can be used for error checking consists of the following code of added bits to the normal data word.

Fig. 7.1 Error check code format

The first M bits represent data, and will be referred to as the data word. The remaining K bits are not directly related to data and are called redundancy bits or the redundancy word. The combination of these two portions form a N bits total word. Such a combination of a data word and a redundancy word is known as a redundancy code.

As an example, let us take the case of M=2 and K=1. As shown in Table 7.1, there are four possible combinations of data word.

Table 7.1 Redundancy Code Example

DW		RW
D_1, D_0	R_0	
0 0	0	
0 1	1	
1 0	1	
1 1	0	

DW : data word
RW : redundancy word

To this data word is added a redundancy word as shown in Table 7.1, the redundancy bit R_0 being given by the following expression.

$$R_0 = D_0 \oplus D_1 \dots \dots \dots (1)$$

where \oplus is the exclusive-OR operator

Next, let us consider the case for which one of the bits is different, that is, the case of a single bit error. Since the word has three bits, for each word there are three possible error words making a total of 12 possible error words. This is summarized in Table 7.2.

Table 7.2 Valid Word and Error Word Combinations

Valid word	Error words		
0 0 0	0 0 1	0 1 0	1 0 0
0 1 1	0 1 0	0 0 1	1 1 1
1 0 1	1 0 0	1 1 1	0 0 1
1 1 0	1 1 1	1 0 0	0 1 0

Table 7.3 Decimal Notation Valid and Error Words

Valid word	Error words		
0	1	2	4
3	2	1	7
5	4	7	1
6	7	4	2

A valid word is one with no errors.

From Table 7.2 and Table 7.3 we see the following

- (1) The set of valid words contains no error words.
- (2) Any valid word differs from other valid words by not less than two bits.

Basically the above two statements are the same. Specifically, valid words differ from each other in not less than two bits so that single bit errors are not found in valid data. In this manner error check is to detect a (h-1) bit error by making valid words differ from each other by h bits to select proper redundancy words. (Selecting thus the set of valid words which does not include error words differing not less than (h-1) bits, so we can distinguish these error words from valid words.) The value h for such an error check code is known as the Hamming distance. When this relationship is expressed in set theory notation we have the representation of Fig. 7.2.

Fig. 7.2 Parity codes classification

Next let us examine the error word. For the error words shown in Table 7.3, the difference from the valid word is in order across the row the first bit, the second bit, and finally third bit. While the same word exists for the error words of any particular row, it is impossible to know which row a particular error word belongs to or phrased differently, although the fact that the word is an error word is determinable, which bit is in error must be known or else the code cannot be used to correct the error. This type of error check is known as error detection.

As the next example, let us take the case where $M=1$ and $K=2$. For this example the data words are shown in Table 7.4 and it can be seen that there are only two types of data words with the redundancy word determined by equation (2).

Table 7.4 Error Correcting Code Example

DW	RW	
D_0	K_1	K_0
0	0	0
1	1	1

$$K_0 = K_1 = D_0 \dots\dots\dots (2)$$

If as in the previous example, we consider a single bit error word, we can derive Table 7.5 and Table 7.6 as shown below.

Table 7.5 Single Bit Error Word Combinations

Valid word	Error words			
0 0 0	0 0 1	0 1 0	1 0 0	
1 1 1	1 1 0	1 0 1	0 1 1	

Table 7.6 Decimal Notation Single Bit Error Words

Valid word	Error words		
0	1	2	4
7	6	5	3

As can be seen from the table, this time there is no ambiguity in the error words. Therefore, the valid word can be obtained merely by looking at the error word. For example, if the word were 001, 010, or 100, the valid data would be clearly 000. However, if the error word were 110, 101, or 011, the original valid word would have been 111. Approaching this differently, let us assume that the word is 001 or 110. Since the error word has the K_0 bit different, reversing the differing bit turns 001 into 000 and 110 into 111 which are the valid data words. The same procedure applies to the other error words which are possible.

In this manner, a redundancy word is used to eliminate ambiguities in the error word and enable the derivation of the valid word by examining the error word. This procedure is known as error correction. Expressed in terms of set theory symbols we have the relationships shown in Fig.7.3

Fig. 7.3 Error correction code relationships

An actual circuit implementation of such an error correction code would involve determining whether the word belonged to W , R^1 , R^2 , or R^3 . If the word was found to belong to the R set, the error correction procedure involves simply inverting the bit corresponding to the error word set.

3, Parity

As discussed in the previous section, some error check techniques involve error words which have duplication and can only be used to detect errors. One particular type of error detection scheme used to detect single bit errors is called parity. The parity error detection method uses a redundancy word one bit long (R_0) regardless of the length of the data word. R_0 is derived in the following manner.

$$R_0 = D_0 \oplus D_1 \oplus D_2 \oplus \dots \oplus D_{m-1} \dots\dots\dots (3)$$

or

$$R_0 = \overline{D_0 \oplus D_1 \oplus D_2 \oplus \dots \oplus D_{m-1}} \dots\dots\dots (4)$$

The single bit derived in equation (3) represents the number of 1's in the total word is even and is termed even parity while equation (4) is referred to as odd parity.

Fig. 7.4 shows the example of an 8-bit data word, using an M74LS280P (SN74LS280) as the parity generator. The M74LS280P has Σ_E and Σ_O as parity outputs and inputs A through I. The input to output relationship being defined by the following expressions.

ERROR DETECTING AND CORRECTING

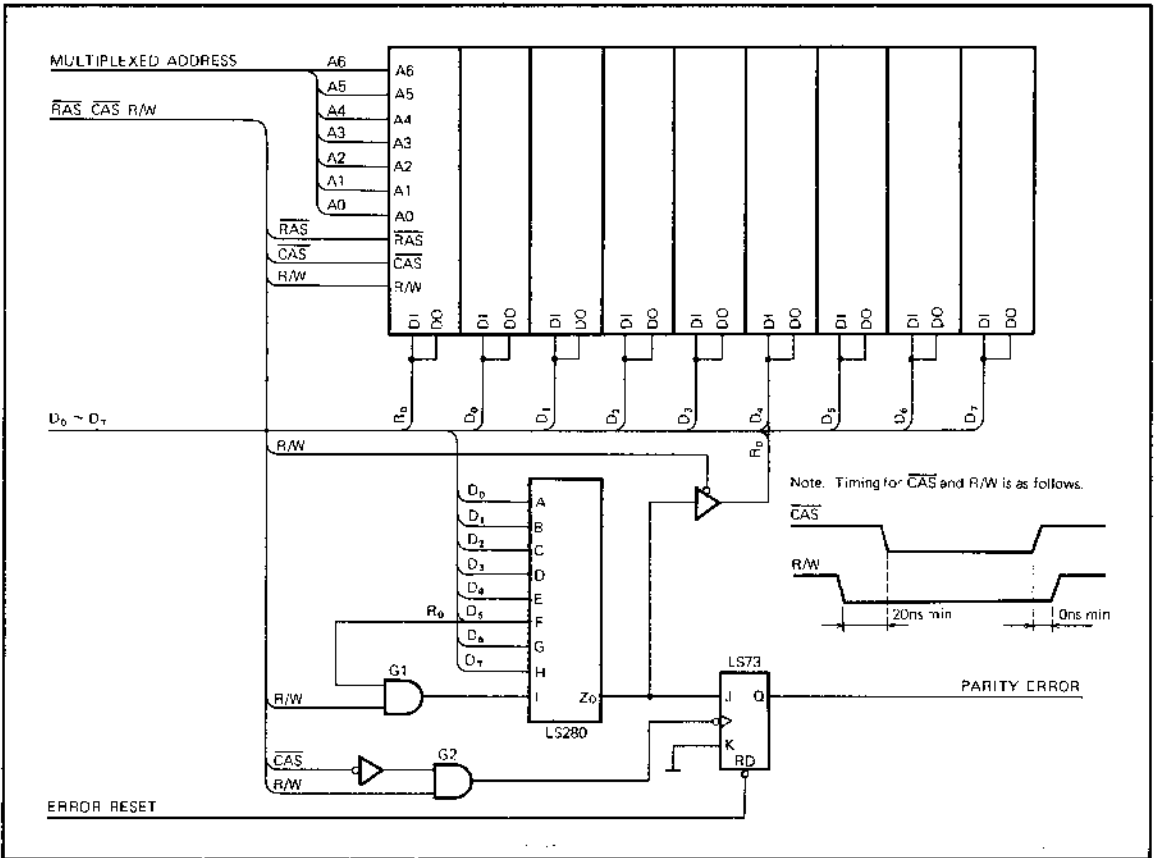

Fig. 7.4 Parity circuit example

$$\Sigma_E = A \oplus B \oplus C \oplus D \oplus E \oplus F \oplus G \oplus H \oplus I \quad \dots (5)$$

$$\Sigma_O = A \oplus B \oplus C \oplus D \oplus E \oplus F \oplus G \oplus H \oplus I \quad \dots (6)$$

For write operations, since G1 makes the I input 0, the parity bit R_{0R} is written into memory with a value given by the following expression.

$$R_{0W} = \Sigma_{0W} = D_{0W} \oplus D_{1W} \oplus \dots \oplus D_{7W} \quad \dots (7)$$

where $D_{0W} \sim D_{7W}$ is the write data

Next, for read operations, all of the read data (including parity) is input to the M74LS280P. Therefore the output is given by the following expression.

$$\Sigma_{0R} = D_{0R} \oplus D_{1R} \oplus \dots \oplus D_{7R} \oplus R_{0R} \quad \dots (8)$$

If no errors are present in $D_{0R} \sim D_{7R}$, then they become equal to $D_{0W} \sim D_{7W}$ and R_{0W} , equation (8) replacing (7).

$$\Sigma_{0R} = R_{0R} + R_{0R} = 0 \quad \dots (9)$$

The JK flip-flop does not change states at the rising edge of CAS. If, however, there is any single bit error in $D_{0R} \sim D_{7R}$ or R_{0R} , the following expression is derived from equation (7).

$$R_{0R} = \overline{D_{0R} \oplus D_{1R} \oplus \dots \oplus D_{7R}} \quad \dots (10)$$

When this is substituted for equation (8), we have the following.

$$\Sigma_{0R} = \overline{R_{0R}} + R_{0R} = 1 \quad \dots (11)$$

Upon the rising edge of \overline{CAS} , the JK flip-flop output goes to 1 indicating the presence of an error.

ERROR DETECTING AND CORRECTING

4. Single-Bit Error Correction

The detection and reversal (correction) of a single bit error is referred to as single-bit error correction (SEC). For SEC to be possible the Hamming distance for the total word must be a minimum of 3-bits and the following equation must be satisfied. Examples of allowable values of M are given in Table 7.7.

$$2^K - 1 \geq N$$

where $N = M + K$ (12)

Table 7.7 Allowable M values

K	$\leq M \leq$
4	4~11
5	12~26
6	27~57
7	58~120
8	121~245

SEC is an extension of the parity concept. For instance, let us take the case of $M = 16$. From the Table we see that $K = 5$ from which $N = 16 + 5 = 21$. In single-bit error correction, each bit of the redundancy word is given a

check bit weight, from which the location of the error bit can be determined. To implement this scheme a 21-bit total word is generated.

Bit number	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
Data word	D ₁₅	D ₁₄	D ₁₃	D ₁₂	D ₁₁	D ₁₀	D ₉	D ₈	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀						
Redundancy word						R ₄						R ₃						R ₂		R ₁	R ₀	
Weight of redundancy bit	R ₀	x		x		x		x		x		x		x		x		x		x		x
	R ₁			x	x			x	x		x	x				x	x			x	x	
	R ₂	x	x					x	x	x	x					x	x	x				
	R ₃						x	x	x	x	x	x	x									
	R ₄	x	x	x	x	x	x															

Fig. 7.5 SEC Weighting

Whereas for parity the R₀ has the weight for all bits, SEC, as shown in Fig. 7.5, assigns weights (2 bits) R₀~R₄ in a binary coded fashion. Specifically the weights are given in equations (13) through (17) below.

$$R_0 = D_0 \oplus D_1 \oplus D_3 \oplus D_4 \oplus D_6 \oplus D_8 \oplus D_{10} \oplus D_{11} \oplus D_{13} \oplus D_{13} \oplus D_{15} \dots (13)$$

$$R_1 = D_0 \oplus D_2 \oplus D_3 \oplus D_5 \oplus D_6 \oplus D_9 \oplus D_{10} \oplus D_{12} \oplus D_{13} \dots (14)$$

$$R_2 = D_1 \oplus D_2 \oplus D_3 \oplus D_7 \oplus D_8 \oplus D_9 \oplus D_{10} \oplus D_{14} \oplus D_{15} \dots (15)$$

$$R_3 = D_4 \oplus D_5 \oplus D_6 \oplus D_7 \oplus D_8 \oplus D_9 \oplus D_{10} \dots (16)$$

$$R_4 = D_{11} \oplus D_{12} \oplus D_{13} \oplus D_{14} \oplus D_{15} \dots (17)$$

In this manner the redundancy bits R₀ through R₄ are generated and written into memory along with the data bits D₀ to D₁₅. For read operations, $\Sigma_{0R0} \sim \Sigma_{0R4}$ are examined as was explained for parity checking. Should there be no errors, $\Sigma_{0R0} = \Sigma_{0R1} = \Sigma_{0R2} = \Sigma_{0R3} = \Sigma_{0R4} = 0$. Let us assume that a single-bit error occurs, for instance at the 11th bit (D_{W6}). R₀, R₁, and R₃ are used as check bits for the 11th bit so that from equation (13) through (17) we have $\Sigma_{0R0} = \Sigma_{0R1} = \Sigma_{0R3} = 1$ and $\Sigma_{0R2} = \Sigma_{0R4} = 0$.

$$\begin{matrix} \Sigma_{0R0} & \Sigma_{0R1} & \Sigma_{0R2} & \Sigma_{0R3} & \Sigma_{0R4} \\ 0 & 1 & 0 & 1 & 1 \end{matrix} \rightarrow \text{decimal } 11$$

This indicates the presence of an error at the 11th bit. Therefore, the error can be corrected by merely reversing this bit (to 1 if it were 0 and 0 if it were 1) to obtain correct data. In a similar manner, if an error occurs at other bits the position will be indicated in binary code by $\Sigma_{0R0} \sim \Sigma_{0R4}$, allowing reversal of the bit after decoding of the position. These Σ_{0R0} through Σ_{0R4} are known as the syndromes.

While we have examined single-bit error correction, for a variety of reasons actual systems make use of double error detection and single-bit error correction.

ERROR DETECTING AND CORRECTING

5. Single-Bit Error Correction/Double-Bit Error Detection

The correction of 1-bit errors and detection of 2-bit errors is known as single-bit error correction/double-bit error detection (SEC-DED). To implement such a SEC-DED scheme, the total word Hamming distance must be at least 4-bits and the following equation must be satisfied.

Table 7.8 gives examples of K and M values.

$$2^K - 1 \geq N$$

where $N = M + K$ (18)

Table 7.8 Allowable M values

K	$\leq M \leq$
4	1 ~ 3
5	4 ~ 10
6	11 ~ 25
7	26 ~ 56
8	57 ~ 119

In SEC, weights are assigned so that the syndrome bits $R_0 \sim R_{K-1}$ are expressed in binary code to indicate directly the position of the error bit. In SEC-DED however, for a

number of reasons, the weighting is assigned as shown in Fig. 7.6 For this reason, decoding of the syndrome is required for error position determination.

Bit number		22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	
Data word		D ₁₅	D ₁₄	D ₁₃	D ₁₂	D ₁₁	D ₁₀	D ₉	D ₈	D ₇	D ₆	D ₅	D ₄	D ₃	D ₂	D ₁	D ₀							
Redundancy word																	R ₀	R ₁	R ₂	R ₃	R ₄	R ₅		
Weight of redundancy bit	R ₀	x				x	x	x		x		x			x		x	x						
	R ₁		x	x				x	x		x		x			x		x		x				
	R ₂	x	x		x		x		x					x	x	x					x			
	R ₃	x	x	x	x	x				x		x	x	x								x		
	R ₅				x	x	x	x	x	x	x				x	x	x	x	x					x

Fig. 7.6 SEC-DED Weighting

$$R_0 = D_0 \oplus D_2 \oplus D_5 \oplus D_7 \oplus D_9 \oplus D_{10} \oplus D_{11} \oplus D_{15} \dots (19)$$

$$R_1 = D_0 \oplus D_1 \oplus D_4 \oplus D_6 \oplus D_8 \oplus D_9 \oplus D_{13} \oplus D_{14} \dots (20)$$

$$R_2 = D_1 \oplus D_2 \oplus D_3 \oplus D_8 \oplus D_{10} \oplus D_{12} \oplus D_{14} \oplus D_{15} \dots (21)$$

$$R_3 = D_3 \oplus D_4 \oplus D_5 \oplus D_{11} \oplus D_{12} \oplus D_{13} \oplus D_{14} \oplus D_{15} \dots (22)$$

$$R_4 = D_6 \oplus D_7 \oplus D_8 \oplus D_9 \oplus D_{10} \oplus D_{11} \oplus D_{12} \oplus D_{13} \dots (23)$$

$$R_5 = D_0 \oplus D_1 \oplus D_2 \oplus D_3 \oplus D_4 \oplus D_5 \oplus D_6 \oplus D_7 \dots (24)$$

From equations (19) through (24) we have the following expression.

$$C_D = R_0 \oplus R_1 \oplus R_2 \oplus R_3 \oplus R_4 \oplus R_5$$

$$= D_0 \oplus D_1 \oplus D_2 \oplus D_3 \oplus D_4 \oplus D_5 \oplus D_6 \oplus D_7 \oplus D_8$$

$$\oplus D_9 \oplus D_{10} \oplus D_{11} \oplus D_{12} \oplus D_{13} \oplus D_{14} \oplus D_{15} \dots (25)$$

The righthand side of equation (25) is the same as the parity expression. Therefore, for read operations, examination of C_{DR} is given by the following.

$$C_{DR} = \Sigma_{OR0} \oplus \Sigma_{OR1} \oplus \Sigma_{OR2} \oplus \Sigma_{OR3} \oplus \Sigma_{OR4} \oplus \Sigma_{OR5}$$

Examination of this value indicates whether or not a 2-bit error is present (the parity can only indicate whether the number of error bits is odd or even. Therefore it is ineffective for more than 2-bits of error. In contrast to this, the SEC-DED scheme provides a no error/1-bit error syndrome detection capability which detects an even number of error bits as a 2-bit error).

Table 7.9 shows a summary of read error detection for various types of errors.

Table 7.9 applies to errors of 2 bits or less.

Fig. 7.7 is the circuit implementation for the expressions of equation (19) through (25). In actual systems, the detection of an error results in data being latched and corrected, whereupon it is rewritten into memory and the

control circuits for these operations would be required as well.

The decoding of $\Sigma OR0$ through $\Sigma OR5$ by the SN74S138 and SN74SD2 is shown in the following Table 7.10.

1. Effective Subroutine Program Procedures

These procedures are effective in reducing memory size of the program and increasing program execution speed. Convenient instructions that are used in subroutines are discussed.

1.1 Subroutine call instructions

The following four instructions can be used as subroutine call instructions:

BM, BMA, BML, BMLA

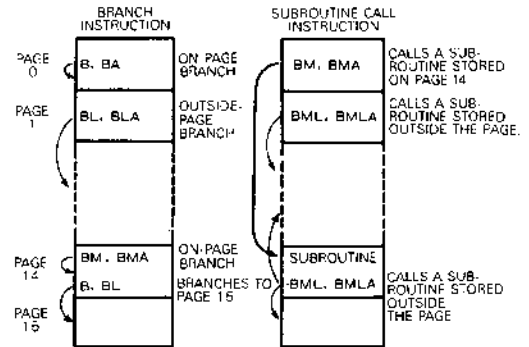

The BM and BMA instructions are one-word instructions that can call all the subroutine stored in page 14. These instructions are designed to designate page 14 automatically by hardware action. If the entrance of a subroutine is programmed on page 14, the subroutine can be called by these one-word instructions, which reduces programming memory requirements.

When the BM, BMA, B or BA instruction is executed on page 14 (in other words, when any of these instructions are used on page 14) the BM and BMA instructions will operate as a branch on page 14 and the B and BA instructions will operate as a branch on page 15. When any of the RT, RTS, BL, BLA, BML and BMLA instructions is executed, this special function is cancelled and BM, BMA, B and BA no longer have a special function. That is, the BM and BMA instructions operate as subroutine call instructions on page 14 and the B and BA instructions as on-page branch instructions. Details of these functions are explained in Fig. 1.

In case the whole subroutine cannot be stored on page 14, only the entrance to the subroutine should be stored on page 14. The balance of the subroutine programs should be

stored on another page and branched to. Page 14 can be used without any problems for programs other than subroutines.

Fig. 1 Subroutine call instructions

Note 1 The B and BA instruction will branch on page 15, and the BM and BMA instruction will branch on page 14 if executed without executing an RT, RTS, BL, BLA, BML or BMLA instruction after the execution of a BM or BMA instruction.

1.2 Consecutively described skip instructions

If either arithmetic LA or RAM addressing LAX instructions appear in sequence, only the first instruction will be executed and the successive same instructions are skipped. It is useful for clearing files as shown in Fig. 7.

1.3 In-RAM file designation changing instructions

The following four instructions:

TAM j (where, $j = 0\sim 3$)

XAM j (where, $j = 0\sim 3$)

XAMD j (where, $j = 0\sim 3$)

XAMI j (where, $j = 0\sim 3$),

automatically change the contents of the X register depending on the contents of the Z register. File designation is made by the immediate modifier j ($j = 0\sim 3$). Its designating rules are shown in Table 1. These instructions are very useful for shifting and transferring data within files.

Table 1 In-RAM file designation changing rules using the TAM, SAM, SAMD and SAMI instructions.

Contents of the Z register Value of j	(Z) = 0	(Z) = 1
	0	No change
1	F0⇌F1 F2⇌F3	F4⇌F5 F6⇌F7
2	F0⇌F2 F1⇌F3	F4⇌F6 F5⇌F7
3	F0⇌F3 F1⇌F2	F4⇌F7 F5⇌F6

2. A-D Conversion Programs

A-D conversion is performed by comparing the input voltage of the analog input port K with V_{ref} , which is generated by the D-A converter, and checking the contents of the H-L register until they are the same level. Register Y designates the port K input. For example, the input K_y is selected when the contents of the Y register are y.

There are two methods, successive approximation and sequential comparison, for A-D conversion. Either is selected by means of the program.

2.1 Successive approximation method

Program Operation

In this method, the input voltage in the analog input port $K_{(Y)}$ is converted to an 8-bit digital value using the successive approximation technique, and the result is stored in the H-L register.

Its program flow is shown in Fig. 2. The H-L register is first cleared, and then the C register is set to designate the most significant bit (MSB) of the H-L register. When the instruction CPA is executed after "1" has been set in the MSB, the input voltage in the analog input port $K_{(Y)}$ is compared with the D-A conversion output V_{ref} .

When

$$|V_{ref}| > |V_{K(Y)}|$$

is met during the execution of the next instruction (during the execution of the NOP instruction), $J_{(Y)}$ is set to "1". Otherwise it will be reset to "0"

If

$$|V_{ref}| > |V_{K(Y)}| \quad \text{i.e. } J_{(Y)} = 1$$

the MSB of the H-L register is reset to "0".

If

$$|V_{ref}| < |V_{K(Y)}| \quad \text{i.e. } J_{(Y)} = 0$$

the MSB will remain as "1". Then (C) is decremented by 1, and the above procedure is repeated eight times until reaching the least significant bit (LSB).

When using ports other than those used for analog quantity measurements such as when using port K as a key input port and applying a low level from D_{REF} , program statements 21 and 22 shown in Fig. 4 must be changed as shown below. The original program functions are retained.

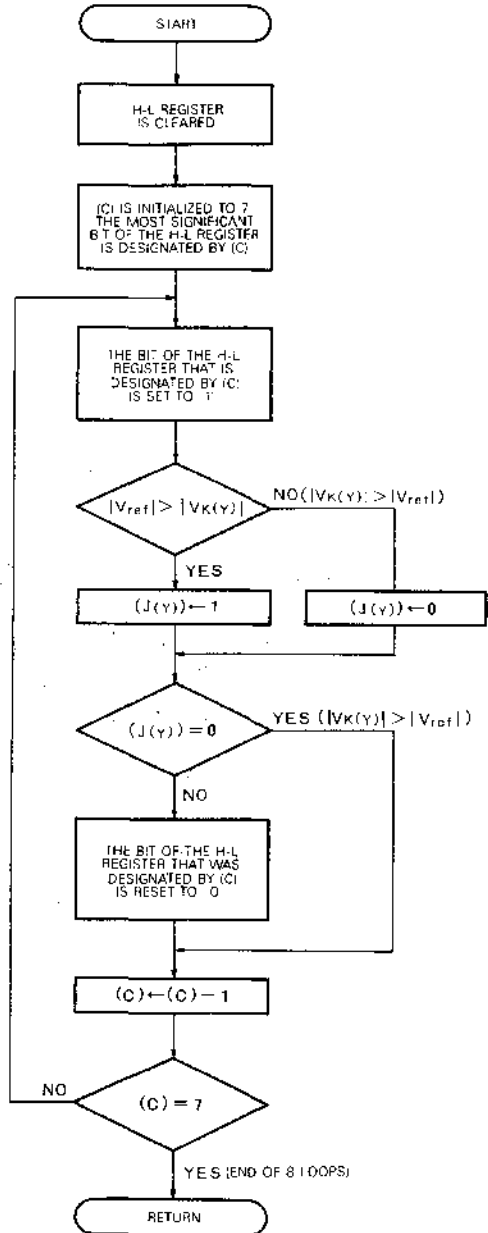

CPA	CPAS
NOP	NOP
	CPAE

This successive approximation method has a constant conversion speed—approximately 0.6ms at 600kHz—and thus it is suitable for examining analog value with large variations and detecting different analog values from multiple channels.

Subroutine Call

The subroutine is called after designating the terminal of the analog input port K and the bit position of the J register with the Y register. A-D conversion is performed

Fig. 2 A-D conversion subroutine flow chart for the successive approximation method

for the port K_0 in the following example.

```
L X Y 0, 0
BM ADC1
```

2.2 Sequential comparison method

Program Operation

In this method, the input voltage in the analog input port $K_{(Y)}$ is converted to an 8-bit digital value using the sequential comparison technique, and the result is stored in the H-L register.

Its program flow is shown in Fig. 3. First the appropriate contents of the H-L register are D-A converted, and the V_{ref} is compared with the input $V_{K(Y)}$.

If $|V_{ref}| > |V_{K(Y)}|$ then (CY) is set to "1" and if $|V_{ref}| < |V_{K(Y)}|$ then (CY) is reset to "0"

The H-L register is decremented when (CY) is 1 and decreases $|V_{ref}|$ by $V_{REF}/256$. Otherwise, the H-L register is incremented, when (CY) is 0, and increases $|V_{ref}|$ by $V_{REF}/256$. The comparison will come to an end when the magnitudes of $|V_{ref}|$ and $|V_{K(Y)}|$ are exchanged.

The contents of the H and L registers are stored in the A register, and the contents of the A register are either incremented or decremented. First, the low-order 4 bits (L register) are incremented or decremented, followed by of the high-order 4 bits (H register), and then the L register again.

To increment the A register, 1 is added to that register. Testing whether the (A) is 15 or not is performed by the A instruction and by checking if the carry is 1. To decrement the A register, 15 is added to the A register. Testing whether (A) is 0 or not is performed by the A instruction and by checking if the carry is 0.

It will test (H) = 0, when $V_{ref} = \frac{0}{256} V_{REF}$ is met, and will test (H) = 15, when $V_{ref} = \frac{255}{256} V_{REF}$ is met.

Subroutine Call

The subroutine call is executed after designating the terminal of the analog input port K and the bit position of the J register with the Y register. A-D conversion is performed for the port K_0 in the following example. However, it will reduce conversion time if the subroutine is called after setting an expected value in the H and L registers, in cases where the digital value can be anticipated.

```
L X Y 0, 0
(H) ← expected value
(L) ← expected value

3. Clear File

Program Operation

These are subroutines that are used in clearing files FO~F7, which are formed in the RAM area and are organized as up to 16 words each. The file organization is shown in Fig. 6. These are subroutines, selected by the Z register, that clear the addresses 0~MAX (MAX = 0~15) or that clear the addresses MIN~15 (MIN = 0~15). After MAX and MIN have been initialized and then an LXY instruction that designates the file number is branched, only the first LXY instruction will be executed, and the successive ones are skipped.

To use CFM to make a subroutine that clears the addresses MIN~MAX designated by the Y register of each file, the instruction set SEY max is inserted after the XAMI 0 instruction.

Subroutine Call

An example of subroutine call is shown in Fig. 7. The constants MAX and MIN first have to be equated by a pseudo instruction. A file group is then selected by the Z register as shown below:

When (Z) = "0": F0, F1, F2, F3

When (Z) = "1": F4, F5, F6, F7

then the BM instruction calls a subroutine of each file unit.

Fig. 6 Function of clear-file subroutine

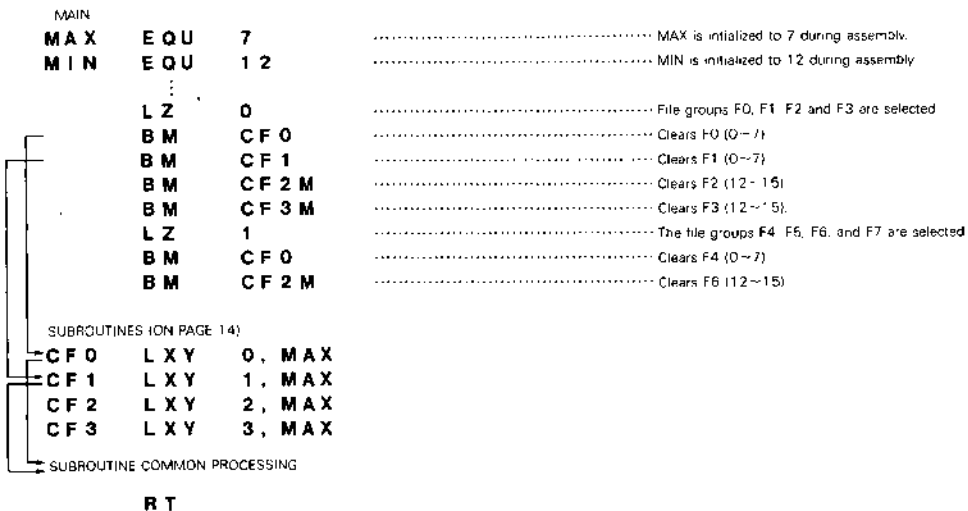

Fig. 7 How to call the clear-file subroutines

4. Right-Shift File

Program Operation

This is a subroutine that is used to right-shift the files F0~F7, as shown in Fig. 8. The contents of address 0~MAX (MAX = 0~15) in a file designated by the Y register are shifted right one digit. The most significant digit (MSD) is filled with 0 and the contents of the least significant digit (LSD) are stored in the A register.

Subroutine Call

The constant MAX has to be equated by using a pseudo instruction. Then the appropriate file group is selected by the X register before calling the subroutine. An example is shown below, in which the digit numbers 0~7 of the file F are shifted right 2 digits

```

MAX EQU 7
:
LZ 1
BM RSF 1
BM RSF 1
    
```

Fig. 8 Example of right-shift file execution

5. Left-Shift File

Program Operation

This is a subroutine that is used to left-shift the files F0~F7, as shown in Fig. 9. The contents of address MIN~15 (MIN = 0~15) in a file designated by the Y register are shifted left one digit. The least significant digit (LSD) is filled with 0 and the contents of the most significant digit (MSD) are stored in the A register.

A subroutine that is to left-shift MIN~MAX can be made by inserting

```
SEY max
```

following the XAMI 0 instruction. When MIN = 0 is equated, it performs the same digits as the right-shift file subroutine. The instruction SEY, however, may be omitted when the skip condition is altered by the optional XAMI instruction.

Subroutine Call

The constant MIN has to be equated by using a pseudo instruction. Then the appropriate file group is selected by the Z register before calling the subroutine. An example is shown below, in which the digit numbers 12~15 of the file F7 are shifted left one digit.

```

MIN EQU 12
:
LZ 1
BM LSF 3
    
```

Fig. 9 Example of left-shift file execution

6. Transfer of File

Program Operation

This is a subroutine that is used for transferring the contents of the files F0~F7. The data (MAX + 1 words) in the addresses 0~MAX (MAX = 0~15) of the file designated by the Y register is transferred.

As already discussed in section 1.3, changing file designation in the RAM is automatically performed by the TAM j and XAMD j instructions. An example is shown in Fig. 10, in which the contents of the file F0 are transferred to the file F1. Each time the TAM 1 and XAMD 1 instructions are executed, the designated file changes to F0→F1→F0... and so on.

Data-transfer subroutines of the address MIN~15 can be made by changing MAX to MIN and the XAMD j instruction to XAMI j.

Subroutine Call

The constant MAX has to be equated by using a pseudo instruction. Then the appropriate file group is selected by the Z register before calling the subroutine. An example is shown below, in which file F0 is transferred to file F1 and F5 to F7. Digits transferred in each file are 0~7.

```

MAX EQU 7
:
LZ 0
BM TF 1 0
LZ 1
BM TF 3 1
    
```

Fig. 10 File transfer example of (F1) ← (F0)

Note 2: The arrows show how the file is changed.

7. File Exchange

Program Operation

This is a subroutine that is used for exchanging the contents of the files F0~F7. The data (MAX + 1 words) in the addresses of 0~MAX (MAX = 0~15) of the designated files is exchanged.

Exchanging of in-RAM files is performed by the TAM j and XAM j instructions.

Data-exchange subroutines of the address MIN~15 (MIN = 0~15) can be made by changing MAX to MIN and the XAMD 0 instruction to XAMI 0.

Subroutine Call

The constant MAX has to be equated by using a pseudo instruction. Then the appropriate file group is selected by the Z register before calling the subroutine. An example is shown below, in which file F0 is exchanged with file F1 and F4 with F7. Digits exchanged in all files are 0~7.

```

MAX EQU 7
:
LZ 0
BM EXF01
LZ 1
BM EXF03
    
```

8. Increment/Decrement Memory

Program Operation

This is a subroutine that is used to increment or decrement the contents of a specific word in the RAM. The specific addresses that can be incremented or decremented are shown below.

```

M(z, 0, 0) (F00 or F40)
M(z, 1, 11) (F111 or F511)
M(z, 2, 13) (F213 or F613)
M(z, 3, max) (F3max or F7max)
    
```

Other addresses can be programmed by changing the LXY x, y instruction.

Subroutine Call

The appropriate file group is selected by the Z register before calling the subroutine. An example is shown below, in which M (0, 0, 0) is incremented and M (1, 2, 13) is decremented:

```

LZ 0
BM INMO00
LZ 1
BM DEM213
    
```

9. Skip Non-Zero Memory

Program Operation

This is a subroutine that is used in test if the contents of specific words in the RAM are 0. The specific addresses that can be tested are shown below.

```

M(z, 0, 0) (F00 or F40)
M(z, 1, 11) (F111 or F511)
M(z, 2, 13) (F213 or F613)
M(z, 3, max) (F3max or F7max)
    
```

If the contents of the specified address of the RAM are 0, the program execution returns to the instruction following the one that called the subroutine. If the contents are not 0, this instruction is skipped, and the return is to the second instruction following the call.

Other addresses can be tested by changing the LXY x, y instruction.

Subroutine Call

The appropriate file group is selected by the Z register before calling the subroutine. When the contents of the RAM are 0, execution returns to the following instruction. When the contents of the RAM are not 0, the execution returns to the second instruction.

The following is an example in which the contents of M (1, 1, 11) are tested:

```

LZ 1
BM SNM111
    
```

INST 1 ← Return if "0"

INST 2 ← Return if "1"

10. Skip Non-Zero File

Program Operation

This is a subroutine that is used to test if all the words of files F0~F7 are 0. There are two subroutines applicable: one for testing the addresses 0~MAX (MAX = 0~15) and the other for testing the addresses MIN~15 (MIN = 0~15).

If the contents of the specified file are 0, the program execution returns to the instruction following the one that called the subroutine. If the contents are not 0, this instruction is skipped, and the return is to the second instruction following the call.

In case of digit MIN~MAX, a program can be made by inserting SEY MAX next to the instruction XAMI 0 of the subroutine SNFM1.

Subroutine Call

The appropriate file group is selected by the Z register before calling the subroutine. In case the contents of the file are 0, the program execution returns to the instruction following the one that called the subroutine. If the contents are not 0, the program execution skips this instruction. An example is shown below, in which the contents of the file F0₀~F0₇ are tested.

11. BCD Addition of Files

Program Operation

This is a subroutine that is used to perform addition in the BCD mode among the files F0~F7. It performs BCD addition of 16-MIN digits in the addresses MIN~15 (MIN = 0~15). The flowchart is shown in Fig. 14, and an example is shown in Fig. 15.

First, the carry CY has to be cleared. The file FX1 is BCD compensated by adding 6 to its contents. Then the contents of the FX2 are added to the contents of the FX1 and the carry is checked. When the carry is off, 10 is added to its contents, which is the same as subtracting 6, and there is no need to BCD adjust. The files FX1 and the FX2 can be alternated by the TAM j and XAMI j instructions. When the BCD addition of the most significant digit is completed, the contents of the carry CY are checked. If (CY) = 0, the program execution returns to the main program after skipping the instruction following the call. When (CY) = 1, indicating an overflow, the program execution will return to the instruction following the call. It is possible to test for overflow state by testing the CY. In this case, the instruction following the instruction SZC is replaced with the instruction RT.

Selection of the files FX1 and the FX2 is made by changing x of the LXY x, y instruction and j of the TAM j and XAMI j instructions.

SUB-ROUTINE	x	j	(FX1) ← (FX1) + (FX2)
ADF 10	0	1	(F1) ← (F1) + (F0) or (F5) ← (F5) + (F4)
	0	2	(F2) ← (F2) + (F0) or (F6) ← (F6) + (F4)
	0	3	(F3) ← (F3) + (F0) or (F7) ← (F7) + (F4)
ADF 01	1	1	(F0) ← (F0) + (F1) or (F4) ← (F4) + (F5)
	1	2	(F3) ← (F3) + (F1) or (F7) ← (F7) + (F5)
	1	3	(F2) ← (F2) + (F1) or (F6) ← (F6) + (F5)
ADF 32	2	1	(F3) ← (F3) + (F2) or (F7) ← (F7) + (F6)
	2	2	(F0) ← (F0) + (F2) or (F4) ← (F4) + (F6)
	2	3	(F1) ← (F1) + (F2) or (F5) ← (F5) + (F6)
ADF 23	3	1	(F2) ← (F2) + (F3) or (F6) ← (F6) + (F7)
	3	2	(F1) ← (F1) + (F3) or (F5) ← (F5) + (F7)
	3	3	(F0) ← (F0) + (F3) or (F4) ← (F4) + (F7)

Subroutine Call

The value j has to be equated by using a pseudo instruction. The appropriate file group is selected by the Z register before calling the subroutine. The program execution will skip the instruction following the subroutine call when the result of the BCD addition is correct, and return to this instruction when there is an overflow. An example of (F0₁₅~F0₁₂) ← (F0₁₅~F0₁₂) + (F1₁₅~F1₁₂) is shown below:

```

MIN EQU 12
J EQU 1
      :
      LZ 0
      BM ADF01
Instruction 1 ← Return if overflow
Instruction 2 ← Return if no overflow
    
```

Fig. 14 BCD file addition subroutine flowchart

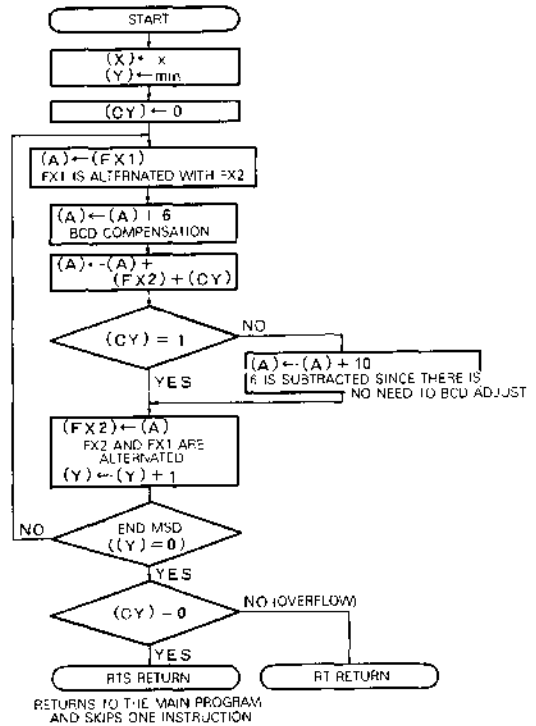

Fig. 15 BCD file addition (example of (F0) ← (F0)+(F1))

Note 3. The arrows show how the file is changed.

12. BCD Subtraction of Files

Program Operation

This is a subroutine that is used to perform subtraction in the BCD mode among the files F0~F7. It performs BCD subtraction of 16-MIN digits of the address MIN~15 (MIN = 0~15).

It has the same program procedure as BCD addition, performing subtraction by adding the 1's complement. When the borrow is 1, BCD adjustment is performed by adding 10.

File selection of the files FX1 and FX2 is made by changing x of the LXy x, y instruction and j of the TAM j and XAMI j instructions, as in BCD addition. Please refer to the procedure given in the section for BCD addition.

Subroutine Call

The value j has to be equated by using a pseudo instruction. An appropriate file group is selected by the Z register before calling the subroutine. The program execution will skip the instruction following the subroutine call when the result of the BCD subtraction is correct, and return to the next instruction when subtraction results in a carry. An example of (F7₁₅~F7₁₂) ← (F7₁₅~F7₁₂) - (F5₁₅~F5₁₂) is shown at right:

```

MIN EQU 12
J EQU 2
:
LZ 1
BM SBF 3 2
Instruction 1 ← Return if overflow
Instruction 2 ← Return if no overflow
    
```

13. Sign Change of file

Program Operation

This is a subroutine that is used to invert the sign in the sign digit, SIGN (SIGN = 0~15), of the files F0~F7. The positive state is indicated when the 8 bit is 0, and the negative state when the 8 bit is 1. Thus inversion is attained by adding 8 to memory.

Subroutine Calling Method

Pseudo instructions are used to fix the code digit. Register Z specifies the file group and the subroutine is called. Next, the 12th digit of file F0 is inverted as shown.

```

SIGN EQU 12
:
:
LZ 0
BM SCFO
    
```

MITSUBISHI MICROCOMPUTERS APPLICATION OF MELPS 4 SINGLE-CHIP 4-BIT MICROCOMPUTER

(M58840-XXXP) IN A MICROWAVE OVEN

DESCRIPTION

A typical example of an application in which a Mitsubishi MELPS 4 single-chip 4-bit microcomputer is used in the microwave oven.

The system is designed to control the magnetron, fan and buzzer of the microwave oven by the touch-keyboard input, and to display the time and temperature, along with the power, on the large fluorescent display tube, as well as displaying the MODE on the LEDs (8 pieces). Its features include controls for designating the start-up time and controlling the defrosting process (time and power), the cooking process #1 (time, temperature and power) and the cooking process #2 (time, temperature and power). In addition, the clock can be used as an independent timer.

The program for the microwave oven application is stored in the M58840-001P.

FEATURES

- Programmed operation for DEFROST, COOK 1 and COOK 2 processes
- Time, temperature and power controls
- Clock and timer
- Display of the time, temperature and power on the large fluorescent display tube
- The simplification in circuit design facilitates cost reduction and miniaturization of the oven.

FUNCTION

1. Microwave Oven Function

(1) Outline of operation

When the start key is depressed after setting up the cooking conditions (time, temperature and power) through the touch key, the oven starts operating in the following sequence regardless of the order the conditions were keyed in.

As soon as one process is completed, the next process is started, skipping those processes that are not designated, until finished. In addition, the clock can be used as an independent timer.

(2) Clock

The clock has a 12-hour dial and indicates hours and minutes.

(3) Timer

The timer actuates the buzzer at the specific time designated in minutes and seconds.

(4) Start time

It designates the start time and starts the cooking when that specific time is reached.

(5) Defrosting

Power and time can be selected for defrosting, but when no power setting is made, the oven automatically uses a 50% setting. During the set time, the system

controls the magnetron, on and off, to maintain the power specified, and turns the magnetron off as soon as the specific period is over. The oven is kept in this halt condition for the duration.

(6) COOK 1

The operating power, temperature and time can be selected for this process. If no specific power is designated, the oven automatically uses a 100% setting. The operating temperature can be selected in the range of 35°C~95°C. The magnetron is operated, on and off, at the power setting after the cooking has started until the selected temperature is reached. Although the magnetron is turned off after reaching the selected temperature, it is turned on again when the temperature in the oven falls 3°C below the selected temperature. This procedure is repeated until the time is reached for completion of the COOK 1 process.

When no temperature setting is made, the oven operates at the power specified and completes the COOK 1 process when the set time is reached.

(7) COOK 2

The procedures for COOK 2 are the same as those for COOK 1.

(8) Clear

The clear switch is used to change key entries or to advance to the next process and discontinue the process in operation.

(9) Reset

Depressing the reset key terminates the entire cooking process and shifts to clock operation.

(10) Stop

When the stop key is depressed or the door is opened, the cooking process is interrupted. The start key has to be depressed again if the operation is to be resumed.

(11) Display

The operating time, power and temperature are displayed on the fluorescent display tube. The tube displays key-entry data during the key entry. The clock is displayed on the screen by the use of the CLOCK key. It usually indicates remaining cooking time during the cooking operation, but memory contents can be recalled for the clock, power and temperature settings. The oven temperature can also be displayed.

The cooking mode is indicated on the LED.

2. Inputs

(1) Key input: K₀~K₇

22 keys are arranged in a matrix through the K ports and the D ports, using the touch keyboard for input. All inputs are checked 8 times in a 100ms period before being accepted as valid. This is done to prevent errors in operating the oven. Furthermore, successive key entry cannot be made until it is confirmed 8 times in a period of 100ms that there were no keys depressed.

MITSUBISHI MICROCOMPUTERS
APPLICATION OF MELPS 4
SINGLE-CHIP 4-BIT MICROCOMPUTER

(M58840-XXXP) IN A MICROWAVE OVEN

The following 22 keys are provided: defrost (DEFR), cook 1 (COOK 1), cook 2 (COOK 2), temperature (TEMP), power (POWER), start (START), stop (STOP), clear (CLEAR), reset (RESET), timer (TIMER), clock (CLOCK), start time (S. TIME) and numbers (0~9).

(2) Time detection input: K_{13}

This input is used to count the time. Rectified AC waveform from the power source is applied.

(3) 50/60Hz switching input: K_9

This input is used to compensate for the power source, 50Hz or 60Hz.

(4) Temperature sensor input: K_{11}

Voltage appropriate to the temperature is applied from the thermistor located in the temperature probe.

(5) Temperature probe SW input: K_8

This input is used in checking whether the temperature probe is operating.

(6) Door SW input, K_{10}

This input is used to check whether the door is open.

(7) Touch keyboard comparison voltage setup input: K_{14}

This is an input with which the detection level is set up for the touch keyboard. It very useful when the specifications of the touch keyboard are altered.

3. Outputs

(1) Magnetron control output: D_4

The magnetron is activated with a high-level output, and disabled with a low-level output. Alternate on/off operations are repeated with the designated power (duty) in units of 30 seconds. For instance, the magnetron is activated for a period of 9 seconds and disabled for a period of 21 seconds, when the power setting is 30%. It also provides on/off action for controlling the temperature.

(2) Fan output: D_3

The fan is started as soon as the DEFROST, COOK 1 or COOK 2 process is begun, and is turned off as soon as the stop switch is depressed or the cooking process is completed.

(3) Buzzer output: D_5

There are three buzzer-control outputs.

0.2-second buzzer . . . This buzzer is activated each time a validated key entry is made.

0.5-second buzzer . . . This buzzer is activated each time one stage is completed.

3-second buzzer . . . This buzzer repeats 0.2-second intermittent actuation for a period of 3 seconds when the timer completes its counting or the cooking process is completed.

(4) Fluorescent display tube: $S_0 \sim S_7, D_6 \sim D_9, D_2$

A large fluorescent display tube can be driven directly with these outputs. (With maximum output voltage of 33V, and maximum of 15mA for the D ports and a maximum of 8mA for the S ports.)

The display is activated dynamically, and its duty is

about 1/14, with an on duration of 0.9ms.

The following type of a display is taken into consideration. When indicating the temperature and a "C" is displayed in the least significant column, the colon in the center of the display is not displayed. Also for power display the colon is not displayed, and a "P" is displayed in the least significant column.

(5) LED display: $S_0 \sim S_7, D_{10}$

Key entry number or the cooking mode is displayed on the LED, and the contents of one or more of the following are displayed: [S. TIME], [DEFR], [COOK 1], [COOK 2], [TIMER], [START], [STOP], and [TEMP].

The LED is activated dynamically, and its duty is about 70%, with an on duration of about 9ms.

(6) Capacitive panel detection outputs, $D_0 \sim D_2$

Inverted D-port outputs are amplified and supplied to the touch keyboard in order to identify the key depressed in the matrix through the K ports.

Output D_2 is used for displaying the colon on the fluorescent display tube.

4. Key Entries

After depressing a function key, a number key is depressed. Then the data thus entered will be stored in the RAM, after another function key has been depressed, if no error was detected in the data.

(1) Setting the time

Setup of hours and minutes:

Used to set the CLOCK and S. TIME. Must be set within the range of 1:00~12:59.

Setup of minutes and seconds:

Used to set the TIMER, DEFR, COOK 1 and COOK 2 periods.

Must be set within the range of 1 second~99 minutes and 59 seconds.

Error:

When key entry is made over the above upper limits or more than 6 digits are entered, an error indication (EE:EE) is displayed.

An example of setting the clock operation is shown in the following illustration:

Example of key entry (1)

KEY	DISPLAY
1ST STEP (CLOCK)	: 0
2ND STEP (1)	: 1
3RD STEP (2)	: 12
4TH STEP (3)	1:23
5TH STEP (4)	12:34
6TH STEP (START)	12:34

MITSUBISHI MICROCOMPUTERS

APPLICATION OF MELPS 4 SINGLE-CHIP 4-BIT MICROCOMPUTER

(M58840-XXXP) IN A MICROWAVE OVEN

When a key entry error is detected in the fifth or sixth step, an error indication "EE:EE" is displayed, after the CLEAR key has been depressed. Then the data must be reentered. When there is no error in the key entry, the clock operation will start as soon as the start key is depressed.

(2) Setup of duty for the magnetron

The operating power must be set in the following sequence: [POWER] → [DEFER, COOK 1, or COOK 2] → [NUMBERS]. Power duty in the range of 0~100% can be used for COOK 1 and COOK 2 operations, but for the DEFER operation the range is 0~50%. Even though the rate is set over 50% for DEFER, a rate of only 50% will be used because of the limit.

Entry of power duty settings 0~90% is made by depressing one number key that is the desired setting to the closest 10%. An entry of 100% is made by depressing the 1 followed by a 0. Deviating from this will cause an error.

Example of key entry (2)

KEY	DISPLAY
1ST STEP [POWER]	P
2ND STEP [COOK 1]	100P
3RD STEP [?]	20P
4TH STEP [COOK 2]	:0

Automatically 100% of the duty is recalled from the memory in the second step, 20% is displayed in the third step, 20% is stored in the RAM in the fourth step, and then the time of the COOK 2 is recalled from the memory. (But only [0] is displayed in this case, because the data for COOK 2 has not yet been entered.

(3) Setup of temperature

The operating temperature must be set in the sequence of [TEMP] → [COOK 1 or COOK 2] → [NUMBERS]. The temperature must be within the range of 35°C ~95°C. Exceeding this range will cause an error.

5. Data Display

(1) Before the start

Data during key entry is displayed in the manner mentioned previously, but this data can be recalled from memory by depressing the appropriate function key when needed for reference.

Example of key entry (3)

KEY	DISPLAY
1ST STEP [CLOCK]	11:55
2ND STEP [TEMP]	C
3RD STEP [COOK 2]	62C
4TH STEP [COOK 1]	5:30
5TH STEP [POWER]	P
6TH STEP [COOK 2]	60P

In the first step the present time is displayed from the clock. Then the temperature setting for COOK 2 is recalled from memory in the second and third steps. The time setting for COOK 1 is recalled in the fourth step. Then the power setting for COOK 2 is recalled from memory in the fifth and sixth steps.

(2) After the start

After the start key is depressed, the remaining cooking time is displayed, but the following data can be recalled and displayed for 3 seconds.

Power: Depression of the [POWER] key displays the current power setting.

Clock: Depression of the [CLOCK] key displays the time.

Operating temperature: Depression of the [TEMP] key once displays the current operating temperature setting.

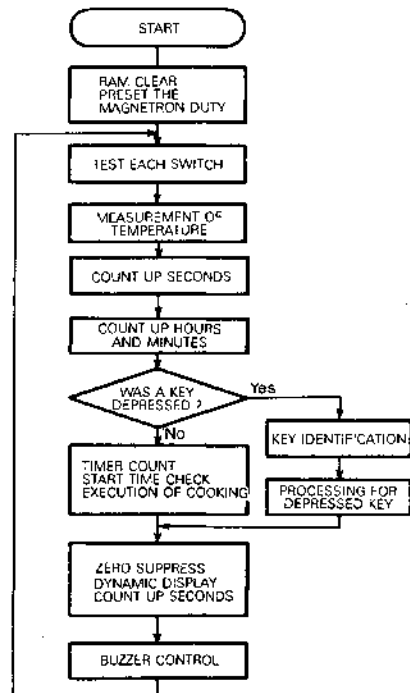

Measured temperature: Depression of the [TEMP] key twice displays of the measured temperature at the present stage.

6. Correction of Data

As the function keys are depressed to recall data, correction of the data can be made by entering the new corrected data after the key operation in the usual manner. To correct the data while in operation, the stop key must first be depressed to stop the operation.

7. General flowchart

A flowchart of the M58840-001P is shown in the following illustration.

MITSUBISHI MICROCOMPUTERS

APPLICATION OF MELPS 4 SINGLE-CHIP 4-BIT MICROCOMPUTER

(M58840-XXXP) IN A MICROWAVE OVEN

8. Routines for Other Applications

Program routines of the M58840-001P that may be suitable for other applications are shown below.

(1) Temperature measurement

After measurement of the temperature, the data, output as H and L signals, is converted to BCD.

(2) Counting seconds

Up to 60 seconds can be counted by supplying the power-supply waveform to the K₁₃ port.

(3) Counting hours and minutes

Up to 12 hours can be counted.

(4) Use of touch keyboards

Depression of a touch-keyboard key can be detected.

(5) Key identification

Up to 22 keys can be identified.

(6) Displaying

A fluorescent display tube and LEDs can be displayed dynamically.

(7) Temperature comparison

Temperature comparison can be made to detect a 2°C fall in temperature for temperature control.

(8) 0.5-second flickering

Display "C" or the LED can be flickered in units of 0.5 seconds.

(9) Count of time

The time settings can be decremented each second, and

used to terminate or start operations when the count reaches 0.

(10) Buzzer control

Buzzer actuation can be controlled for a duration of 0.2, 0.5 or 3 seconds. The 3-second actuation is on-off at 0.2-second intervals.

(11) Time monitoring

Time can be monitored and used to terminate or start operations when the time setting is reached.

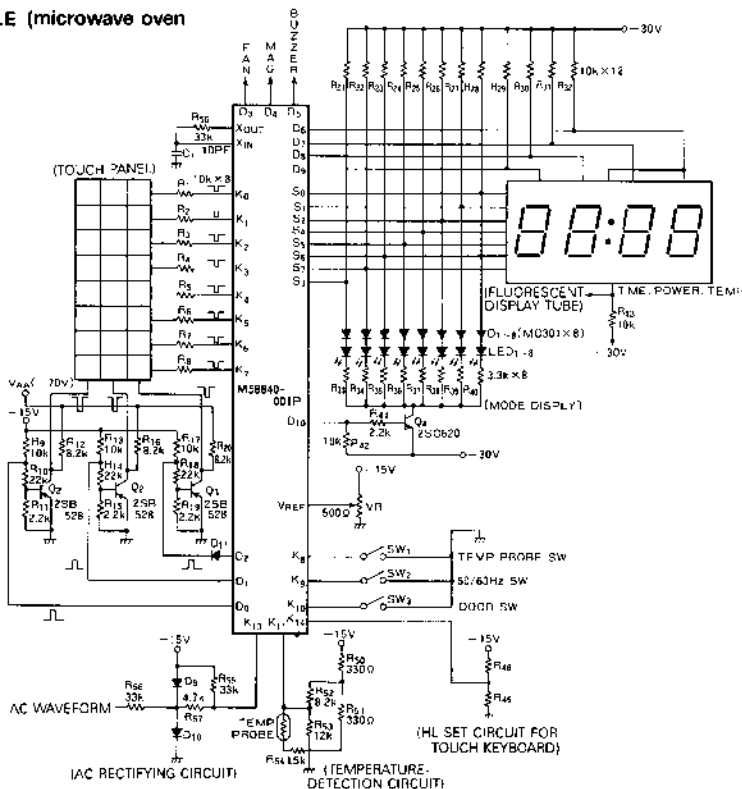

9. Typical control circuit of a microwave oven

A typical example of a microwave oven circuit is shown.

Details of input and output performance are as previously described. Please refer to the information provided for the PCA0402 in regard to capacitive touch-keyboard operation. The diode D₁₁ is provided to prevent counterflow because D₂ is also used for the colon output and display. The temperature-detection circuit K₁₁ compensates for the nonlinear output of the temperature probe and facilitates easy temperature conversion.

The touch-keyboard interface and the A/D conversion circuit are contained in the M58840-XXXP. The wide range of S ports and high maximum output voltage of the S and D ports simplify circuit design. This results in cost reduction, improved performance and improved reliability because fewer parts are required. The use of fewer parts also helps miniaturization.

APPLICATIONS EXAMPLE (microwave oven M58840-001P)

1. CODE-CONVERSION PROGRAMS

There are 4 code-conversion programs for conversions between hexadecimal numbers and their corresponding ASCII code in binary notation. Details of these programs are given below.

Table 1 Correspondence of number formats

Hexadecimal symbols	Machine language binary number	ASCII code in binary notation for hexadecimal symbols
0	0000	00110000
1	0001	00110001
2	0010	00110010
3	0011	00110011
4	0100	00110100
5	0101	00110101
6	0110	00110110
7	0111	00110111
8	1000	00111000
9	1001	00111001
A	1010	01000001
B	1011	01000010
C	1100	01000011
D	1101	01000100
E	1110	01000101
F	1111	01000110

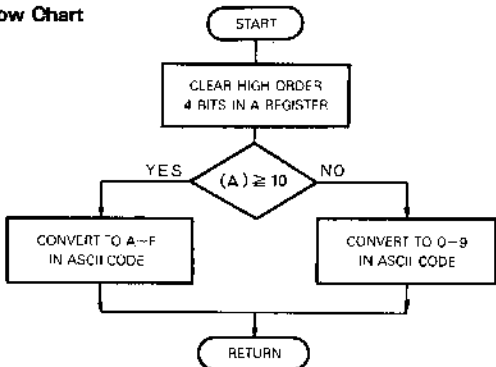

1.1 Binary (4 Bits) to ASCII (1 Character) Conversion (BTA)

This program converts the low-order 4 bits in the A register (a hexadecimal number 0~F) to the corresponding 8-bit ASCII-coded hexadecimal symbol '0'~'F'. The result is retained in the A register. Registers B, C, D, H and L are not affected.

Register Status

Register	Contents at start	Contents at return
A	Binary number to be converted in the low-order 4 bits	8-bit ASCII code
B, C, D, E, H and L		Contents at start

Flow Chart

Program Listing

1.3 ASCII (1 Character) to Binary (4 Bits) Conversion (ATB)

This program converts the 8-bit ASCII code in the C register (a hexadecimal symbol '0'~'F') to a 4-bit binary number 0000~1111. The result is retained in the low-order 4 bits of the A register. If the C register contains a code for a character other than a hexadecimal symbol 0~F, it is recognized as an error; the carry flip-flop is set, and the program is exited. Registers B, D, E, H and L are not affected.

Register Status

Register	Contents at start	Contents at return
A		Hexadecimal number in binary form in the low order 4 bits
D	ASCII coded hexadecimal symbol to be converted	ASCII coded hexadecimal symbol to be converted
B, C, E, H and L		Contents at start

Flow Chart

Program Listing

1.4 ASCII (2 Characters) to Binary (8 Bits) Conversion (ATB 2)

This program converts the two 8-bit ASCII codes in the H and L registers (2 hexadecimal symbols '0'~'F', high order in the H register and low order in the L register) to an 8-bit binary number (0~255₁₀). The result is retained in the A register. If the H or L register contains a code for a character other than a hexadecimal symbol '0'~'F', it is recognized as an error; the carry flip-flop is set, and the program is exited. The D and E registers are not affected.

Register Status

Register	Contents at start	Contents at return
A		8-bit binary number (2 hexadecimal digits)
B		4-bit binary number in the high-order 4-bits conversion of high-order hexadecimal symbol
C		Low-order ASCII coded hexadecimal symbol to be converted
H	High-order ASCII coded hexadecimal symbol to be converted	High order ASCII coded hexadecimal symbol to be converted

2. SORTING PROGRAM (SORT)

This program sorts records (1 byte in length) in descending order. Up to 65 535 records can be sorted. The binary number 255₁₀ cannot be used as data because it is reserved for the end-of-data mark. This data is stored in descending order according to its rank.

The program sorts by comparing a data item with all other data items, thus determining its rank. The data is then stored in descending order according to that rank.

This program can also recall the data associated with any rank. If the rank k ($1 \leq k \leq 65\ 535$) is stored in memory locations ORD and ORD+1, the 1-byte data associated with that rank is stored in the A register, and then control is returned to the user's program. If k is specified as zero, the A register is reset to zero and control is returned to the user's program.

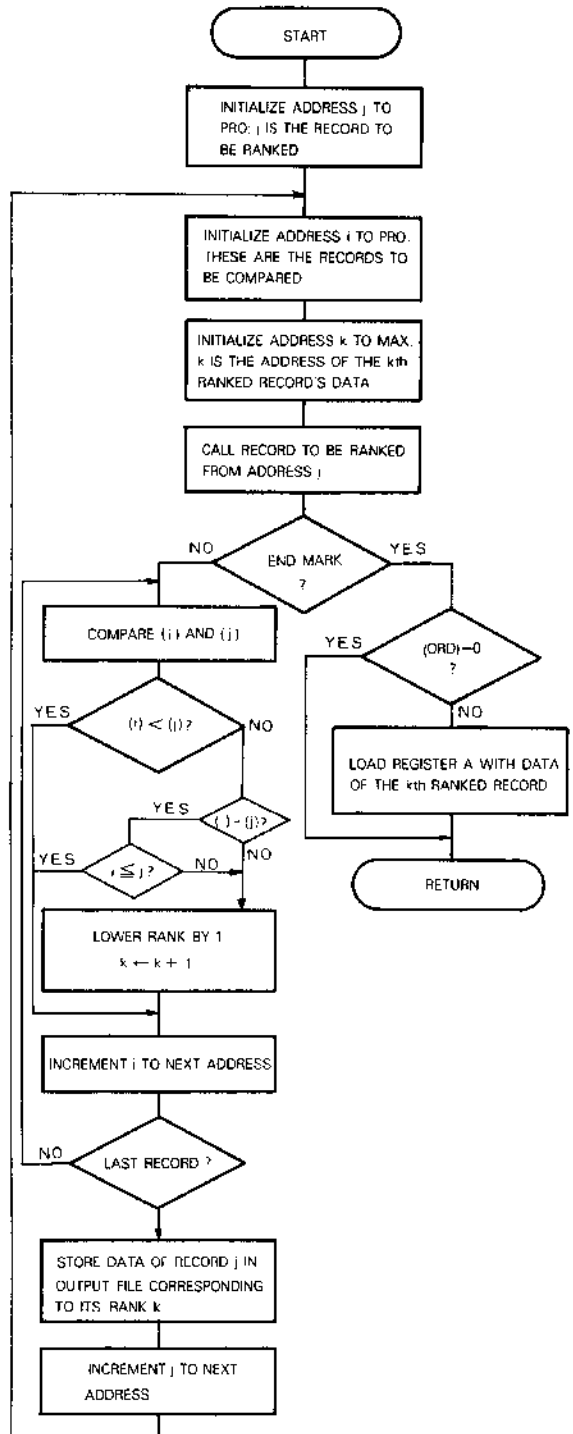

Register Status

Register	Use during execution	Contents changed at return
A	Calculates and recalls data of rank k	yes
B	Storage for data being compared	yes
C	Not used	no
D	Memory address for storing data after ranking	yes
E		yes
H		yes
L	Memory address of data to be ranked	yes

Symbolic Memory Address

Symbolic address	Use during execution	No. of bytes	Contents changed at return	
User's area	ORD	k (the rank of data to be recalled)	2	no
	PRO	Storage area for records to be sorted (PRO is the first address)	n+1	no
	MAX	Storage area for sorted data (MAX is the first address)	n+1	yes
Control area	DADD	Address in PRO of record being sorted	2	no
	RADD	Address in MAX for storing result	2	no
	M1	Address of record to be ranked	2	yes
	M2	Address of record being compared	2	yes
	COUNT	Counter for number of records	2	yes

Flow Chart

APPLICATION OF MELCS 8/2 SINGLE-BOARD COMPUTER

(PCA0801) IN DATA TRANSMISSION THROUGH A MASTER-SLAVE MULTICOMPUTER SYSTEM

DESCRIPTION

Three PCA0801 single-board computers are connected to form a master-slave microcomputer data-transmission system. Such a system contributes significantly to reducing the load on the host computer and to improving the operational efficiency and functions of the system. This is an example of a mode 2 application of the M5L8255AP programmable peripheral interface (PPI).

FUNCTION

One of the three PCA0801s serves as the master computer, and the other two as the slave computers that complete the system. When the No. 1 PPI (C.W.—03₁₆) is set to mode 2, data is transmitted between the master and either of the slaves using the I/O port PA as a bidirectional data bus.

OPERATION

The master computer, storing 200 bytes of the transmission data within its No. 2 EPROM (M5L2708K), starts to transmit that data to the No. 1 slave computer via the I/O port PA (PA₀~PA₇). After receiving the data, the slave computer inverts the data and stores it in its RAM (M5L2111AP). This inverted data is then sent back to the master computer, after which it is stored in the master computer's RAM.

The master computer now starts to transmit 200 bytes of the RAM data to the No. 2 slave computer, where the data is inverted and stored in the RAM to be sent back to the master computer.

The master computer, having completed storage of the data in its RAM, executes an inspection routine for the stored data, and compares the 200-byte contents of the

EPROM and the RAM for discrepancies.

If all the data is correct, LED 1, which acts as an indicator, is turned on. If not, LED 2 is lit, and execution is terminated.

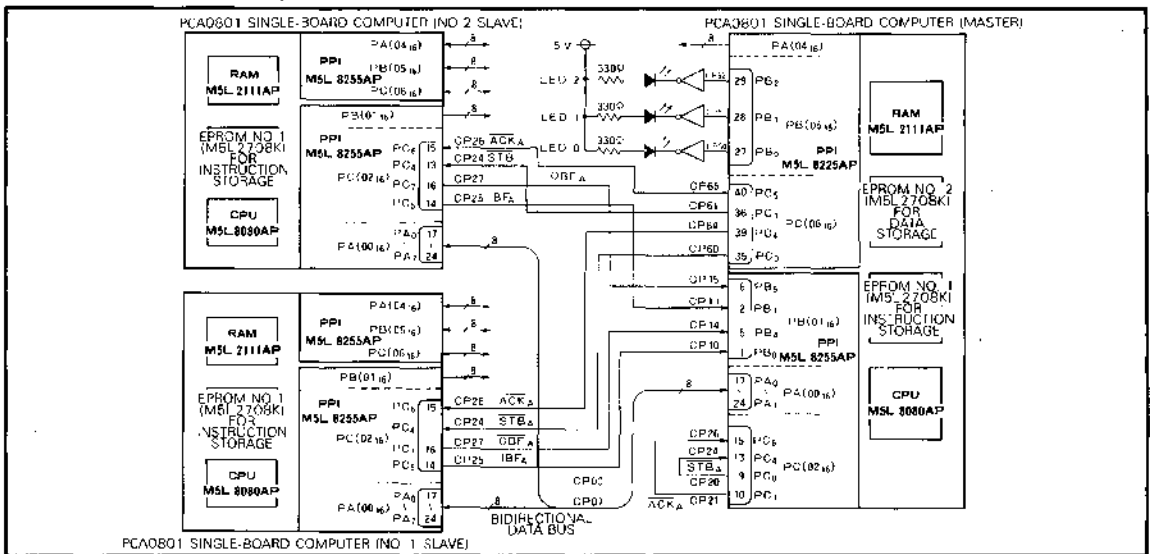

The operational status of the LEDs (on or off), and their significance, are shown in Table 1. These status indications are shown in the sequence of CPU progress, so that the operating status of the master computer may be readily recognized from the combination of LED 0~LED 2 indicators.

Table 1 Status as Indicated by the LED Display

CPU Sequence	LED	LED	LED	Description of the status indicated
	0	1	2	
↑	0	0	0	System is not transmitting data.
↑	0	0	1	Data is being started between the master and slave computer No. 1.
↑	1	0	0	Data is being transmitted between the master and slave computer No. 1.
↑	0	0	0	Data is completed between the master and slave computer No. 1.
↑	0	0	1	System is in the idle condition, with no transmission between the master and slave computer No. 2.
↑	1	1	1	Data is being started between the master and slave computer No. 2.
↑	0	1	0	Data transmission has been completed, having transmitted the data correctly.
↓	0	0	1	Data transmission has completed, but a transmission error has been found.

Note 1 "ON" indicates where the LED turns on, and "OFF" where the LED turns off.
 2 The slave computers, No. 1 and No. 2, must be in operation prior to the engagement of the master computer.
